THE MEALY PLUM APHIS

SOME years ago I read carefully the various published accounts of the life history of the Mealy Plum aphis (Hyalopteris pruni), and since have made many personal observations, of a somewhat detached nature, regarding the habits of the insect. During the past two years I have taken the matter more seriously, with the result that I hope I have settled the question of the life-cycle of this pest of the Plum. The damage done by it is not considered by some writers to be of a very serious nature, but on this point I differ from them. Those in this region who see the dirty appearance of affected Plums can come to no other conclusion than that the damage done must seriously affect the economy of the plant. It is not my intention, at present, to deal with remedial measures, important as they may be, but to give the results of observations carefully carried out almost daily for several months in succession.

In his report on Economic Entomology for 1907 Mr. F. V. Theobald stated that the Mealy Plum aphis appears in July, usually the latter part of the month, but in the previous year he stated that they made their appearance early in the month. Farther on in the report it is said that in the early autumn they all disappear from the Plums, and that unfortunately nothing definite regarding the life-cycle was known; that De Geer had stated he found this aphis on an Apricot, and described both winged male and wingless female; that in September he found an egg with a woolly coat fixed near a leaf-bud. This latter observation of De Geer seems to me the nearest I have seen.

In his Report for 1910 Mr. Theobald says: "It is now known that the Mealy Plum aphis, Hyalopteris pruni, is another form of the Reed aphis, Hyalopteris arundinis, and that a migration takes place between the two host plants."

Buckton states, in his "Monograph": "I consider Hyalopteris arundinis to be distinct from Hyalopteris pruni, from which it differs both in size, in form, and habit." Only the winged and wingless viviparous female are described in Buckton. No mention of "male" "oviparous female," or "eggs" are mentioned.

Dr A. D. Imms, in his Lectures, 1916, at the Manchester University, speaking of the Mealy Plum aphis and their migration, said that they go to Rushes and Aquatic Grasses.

In the *Journal* of the Board of Agriculture for October, 1916, Mr. J. C. F. Fryer has an article on Plum aphides, and gives the life-history of the Mealy Plum aphis, but states that the life-history has not been worked out in this country. "It is chiefly found on Plums," he writes, "during the latter half of summer, and there is a strong probability that the remainder of the year is spent on Grasses and Reeds. In Russia and the United States of

FIG. 1.—MEALY PLUM APHIS: QUEEN MOTHER WITH LARVAE BEFORE AND AFTER THE FIRST MOULT. × 10.

America it is said to live during the winter and early summer on Plums, and the rest of the year on Reeds, but it can hardly have a similar history in Britain."

I think it will be seen from the foregoing accounts that no British entomologists have taken these matters very seriously in hand, but they have depended to a great extent on the theories of others, and I am afraid that this is the case in regard to most of the species of aphides that inhabit the British Isles.

It will be remembered by those who read my article in the *Gardeners' Chronicle* of December 16, 1916, p. 294, that in a reference to the Mealy Plum aphis I said that I found three wingless females producing young on May 16, and that I should be on the look-out for this species earlier in 1917. I kept my promise, and as I had found eggs that I was almost certain were those of the Mealy Aphis, and as I had not found any other species on a particular tree (Plum), I felt almost sure I was on the right track, and I was. On May 7 I found a speci

FIG. 2.—MEALY PLUM APHIS: VIVIPAROUS WINGED AND WINGLESS FEMALES WITH LARVA AND PUPA. × 8.

men that had hatched out—in fact, it had moulted once before I discovered it. On the next day, the 8th, I found another, which seemed to be about the same age. These I labelled No. 1 and No. 2, taking the order of discovery for numeration, and I made daily notes in my book. No. 1 began to produce young on the 17th (May), No. 2 on the 18th. No. 1 produced one per day until the 20th; on the 21st it had nine, on the 22nd fifteen, and so they went on until one insect, No. 1, had produced 60 by the 31st, No. 2 60 on June 2. It is strange, but one of these specimens was on a shoot where I made my observations in 1916, as the old "tally" was left on. Sixty seems to be the maximum number of young produced by one of what I shall call these queen mothers, that hatch from the egg. These, when first hatched, are of a somewhat light olive-green colour, with a darker shade down the back. As time goes on they become lighter in shade; they are short-legged, sluggish creatures, somewhat burly in shape, and die as soon as their young are produced. That shown in fig. 1 I photographed just after it had produced what I considered its maximum number, and with it are four specimens of its family; the two on the upper part of the figures are before and the other two after the first moult. After the first moult they assume the mealy covering and characteristic markings of the species, and are all wingless females in the first generation (i.e., from the mother queen). These mother queens produce all their family on the same leaf. It is difficult to follow all the specimens, as there are many disturbing elements as the season advances—the presence of two or three species of parasitic flies, caterpillars of the winter moth, spiders, the larvae of hover flies, and others—

FIG. 3.—MEALY PLUM APHIS: OVIPAROUS FEMALE LAYING EGGS, FIVE OF WHICH ARE DEPOSITED AT THE BASE OF THE BUD. × 8.

so that it is necessary to have as many specimens under observation as possible to get anything like a true account of the life-history. The generation produced by the queen mother are all wingless females; these latter produce a mixture of winged and wingless ones, as seen in fig. 2. I found the first specimen with fully developed wings on June 20; they go on producing both forms until towards the end of the season. There is a certain proportion of the winged forms about the third generation that divest themselves of their mealy covering, no doubt in preparation for migration. Whether they have hosts other than the Plum I do not know at present, but there is certainly a large proportion that remains on the Plum all the year. They lay their eggs and propagate on the Plum, and large numbers, after mid-season, take possession of the long, sappy shoots (of the Plum) that are produced in the current year. These shoots in many instances become perfectly smothered with them. In August winged females are produced that retain their mealy covering; these seem to be local migrants, i.e., they only travel from place to place on the same tree. They are not nearly so agile as the winged forms produced earlier in the season. They settle down at the end of the month of August and the beginning of September on a

particular leaf, and there produce a brood of from 12 to 20 wingless forms: these specimens are much smaller than the wingless forms of the early season (vivipara ones); they are of a dirty sulphur colour with a light green band down the back. These I proved to be the egg-laying females, and, as far as I can tell, some only are fertile. Although I have watched very closely I have not been able to find males, but I have many times watched these females lay their eggs, and, as will be seen from the illustration, I have been able to photograph them in fig. 3 in the act of egg-laying. Some of these begin egg-laying in the middle of the month of September; on the 25th I watched two lay their eggs. It is very interesting; they travel backwards and forwards along the shoots until they find a suitable position at the base of a bud. When that is fixed upon they back themselves into position and there deposit the egg; the operation sometimes takes half an hour. They generally select the base of a leaf-bud, more particularly right down in the axil, and mostly on the outer or upper side of the shoot. I watched this operation of egg-laying on September 25, 27, and October 2. I found a single female on October 19; this was about the last. In some cases I found as many as six eggs at the base of a bud, but the more general rule is one. The eggs at the time of deposition are soft and flexible, the skin translucent olive-green, over which is a coat of silvery-looking substance that when examined with the microscope is found to be composed of little white-looking rods. After being exposed to the air for some time the eggs assume a more rigid character. I find that many of the eggs are destroyed by some enemy the nature of which I have not yet discovered. Considering that the eggs are laid so early in autumn and hatched so late in spring I would suggest that this species is not so hardy as some others. It will be observed that the eggs are dormant on the trees for seven months in the year. I have preserved specimens of the mother queen and the oviparous females, which, together with eggs and my field of observation, can be seen by appointment by any one interested. The photographs were taken by myself from the specimens under observation. I feel satisfied that I have been able to lift the veil of mystery and to trace the hitherto obscure life stages of this pest. *J. G. Blakey, Bromsgrove Road, Redditch*

LETTERS FROM SOLDIER-GARDENERS.

WITH THE EGYPTIAN EXPEDITIONARY FORCES IN EGYPT AND PALESTINE.

HAVING been unfortunate enough to be sent from the line owing to sickness, and spending four months among the sand hills in front of Gaza, I arrived by easy stages in Cairo, where, as a result of the attentions of the Red Cross Society, I soon became convalescent, and had the good fortune to be able to visit, on November 9, the show of the Egyptian Horticultural Society. This Society usually holds three exhibitions each season, and I was surprised at the healthy rivalry which existed between the various exhibitors, although no actual competition took place.

It would be unfair to compare this exhibition with Chelsea, or Holland House, or the Royal Caledonian Horticultural Society's shows in Edinburgh, but it was a very creditable show, and was held in the beautiful palace of Shereef Pasha, Sharia el Duwawin, Bal el Louk. After considerable trouble, I was fortunate in securing an introduction to the able and courteous secretary, Mr. Brown, who explained to me Egyptian horticultural methods.

A few notes on the show gathered during the course of the afternoon may be of some interest to readers of the *Gardeners' Chronicle*. Among the most noteworthy exhibits was one in the entrance hall, contributed by the Ministry of Agriculture (Horticultural Section). It consisted of bottled fruits and bottled vegetables. Dried fruits of various kinds were also included, while a most interesting collection of Oranges and Lemons aroused great interest on the part of the public. The following were a few of what were the pick of a very rare exhibit:—

FIG. 4. MEALY PLUM APHIS: OVIPAROUS FEMALES. × 18.

Lemon Hindii, a pink-fleshed Lemon about 17 inches in circumference, and beautiful and juicy when cut. Pomilla, Ponderosa Rabba, and the Sham Lemon were all equal in size to Hindii, and were quite a revelation to me. The Gilza, Rough Skin, Seedless, Adelaide Helvia and Jaffa Sweet, were all varieties of sterling merit. In Oranges, the Navelamcia was outstanding. Mandarine Clementini and Duncan's Grape-Fruit were among the best of a most interesting and educational exhibit

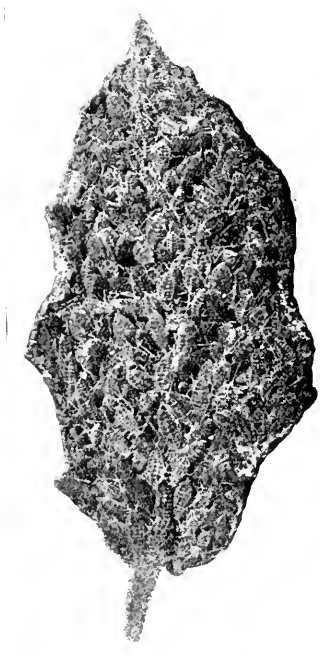

FIG. 5. PLUM LEAF COVERED WITH MEALY APHIS. × 3.

One fruit on each dish had been cut in halves to show the richness of the quality. The Certificate of Merit awarded by the jury was well earned, and the Ministry of Agriculture is to be congratulated on the good work it is doing in fostering the growth of fruits in Egypt. Another most interesting fruit exhibit was contributed by the Traders and Growers' Union, Nurserymen, Gheziret, Dabsha. Staged in quite English fashion, the most conspicuous dishes were Avocada Pear, Persea gratissima, Egyptian Lemon, Citron lanaria, Japanese Kaki, or Diospyros Kaki (these bright scarlet fruits interested me, especially as I had not been able to make a success of them at Tongswood), Mandarines, Syrian Apples, Californian Grape Fruit, Pomelo, Banana, and a most handsome dish of Pomegranates. Another exhibit worthy of its Certificate of Merit award.

Only one exhibit of vegetables was on view, and it was composed of Cauliflowers, Cabbages, Leeks, French Beans, Peas, Beet, Lettuce, Radish, Endive, Tomatos, and Black and White Egg Fruits, the last being the only dish worthy of special notice. In the flower section Chrysanthemums and Roses were most prominent. The exhibit of Border Chrysanthemums disbudded, shown by J. Keatinge, Esq., and awarded a Certificate of Merit, was of sterling quality. The same grower also showed a splendid collection of seedlings grown from seed in 1917; it was composed of Japanese incurved, Singles, and Pompons, which included some really fine sorts, well worthy of being again grown. The Gelzireh Sporting Club was awarded a Certificate of Merit for a group of Chrysanthemums in pots.

In Roses, J. Kershaw, Esq., was awarded the highest award, and a really choice exhibit included the varieties Wm. Sheen, George C. Waud, Viscountess Enfield, Lady Hillingdon, Edward Mawley, Mrs. G. Shawyer, Etoile de France, Dean Hole, Mme. Constant Soupert, Lady Pirrie, Cynthia Forde, and Entente Cordiale.

Mrs. P. W. Stout exhibited a mixed collection which included Roses in variety tastefully staged in vases; also Salvia, Browallia, Brugmansia, and Chrysanthemums, a very attractive and pleasing exhibit. (Certificate of Merit).

Gerbera Jamesonii and its hybrids were well staged by J. S. Cairns, Esq. Hardy Annuals were the subjects displayed by J. Home, Esq., and these were awarded a Certificate of Merit.

The outstanding block of cut flowers was undoubtedly that of J. Hopkins, Esq., and was entirely of Clerodendron splendens. This plant I have never seen in better form or colour (Certificate of Merit). Dahlias found Dr. H. P. Keatinge the only exhibitor, and his exhibit of Dahlia imperialis was most prominent and outstanding.

The entire exhibition was a very successful one, and the thanks of the exhibitors and visitors are due to Mr. Brown, who so successfully carried out the duties of secretary. The duties of a show secretary at home are trying enough, but out here, where English, French, Italian, and Egyptian are gathered together, all speaking their own language, the post must be profoundly difficult. *Charles Shaw, Gardener to C. E. Gunther, Esq., Tongswood Gardens, Hawkhurst, Kent.*

THE ROCK GARDEN.

RANUNCULUS RUTAEFOLIUS

THE pretty Ranunculus rutaefolius, the Rue-leaved Buttercup or Crowfoot, is rare in gardens, though it is an excellent plant for the cool parts of the rockery. The species has pleasing, glaucous, Fern-like leaves and white flowers, with a greenish eye. Although rather cold in its tones, it is a much more pleasing plant than this description would suggest, and grows 6 or 8 inches high. It grows in turf in its native habitats, yet it thrives in flat parts of the rock garden, and I have always found it do best in a situation exposed to the sun, but it needs an abundant supply of moisture. A porous soil of loam, sand, and grit is a suitable rooting medium. It is rather difficult to divide the plant until it is of some size. The nature of the roots would suggest root cuttings as a means of propagation, but I have not been successful in raising plants by this means. *S. Arnott.*

ORCHIDS IN 1917.

DURING the past year the Orchid Committee of the Royal Horticultural Society has awarded nine First-class Certificates and forty-one Awards of Merit to novelties, which is a smaller number than usual. The portraits of these certificated Orchids have been added to the Society's collection, which was begun in 1897, and now numbers 2,384 pictures. The principal exhibits at the R.H.S. shows have been sent by nurserymen.

Messrs. Armstrong and Brown have exhibited continuously, and their awards include two First-class Certificates, thirteen Awards of Merit, and ten Preliminary Commendations. Their Brasso-Laelio-Cattleya Lady Manningham-Buller, which secured a First-class Certificate and the Lindley Medal, was admittedly the finest new Orchid of the year and the best yellow variety ever produced.

Messrs. Charlesworth and Co. obtained four First-class Certificates, ten Awards of Merit, and three Preliminary Commendations. Their Eulophiella Rolfei and Odontoglossum crispum The Premier were remarkable.

Messrs. Sanders, Hassall and Co., J. Cypher and Sons, Stuart Low and Co., J. and A. McBean, and Flory and Black have also contributed to the shows. The silvery-white Brasso-Cattleya Lady Veitch of Messrs. Flory and Black was one of the finest Orchids shown at the fortnightly meetings.

The meetings of the Manchester and North of England Orchid Society have been well patronised, and large numbers of awards have been made by the Committee.

New hybrids have been plentiful, and of these two hundred and sixty have been recorded in the tables published from time to time in these pages. It is interesting as showing the wide interest taken in Orchid hybridisation that while a goodly proportion of novelties are from nurserymen, the greater number has been raised by amateurs. The names of Sir Jeremiah Colman, Sir Geo. L. Holford, Mr. W. H. St. Quintin, Mr. C. J. Phillips, Mr. R. Windsor Rickards, the Duke of Marlborough, Dr. Miguel Lacroze, and Mr. Frederick J. Hanbury, appear frequently in the list of raisers.

Cattleyas, Laelio-Cattleyas, hybrids in which Brassavola Digbyana or Sophronitis grandiflora have been used, Odontoglossums, Odontiodas and Miltonias are still the most popular of Orchids. Most of the novelties have been improvements on existing forms, rather than new crosses likely to give sections with distinctive colours or forms and tending to merge older types, and in some cases nullify the features originally aimed at. For example, the object in using Sophronitis grandiflora and Cochlioda Noezliana as parents was to impart their scarlet colours to the hybrids. This promised well in the first generation, but in after crossings the Sophronitis crosses have been largely merged in the class of Laelio-Cattleyas without scarlet tints, and in the Cochlioda Noezliana hybrids crossing them with Odontoglossum again has resulted in many cases in indifferent Odontoglossums. It would be well to try re-crossing again with Sophronitis and Cochlioda some of those which possess good shape and large size, in order to obtain the scarlet colour again, and it would be well to pursue similar methods with other hybrids that have given results different from the original objective. Steadily but slowly Orchidists are learning more about the probability of crosses in respect to the influence of certain parents and colour production.

It is known that certain well-marked species with desirable qualities transmit their features to succeeding generations. Odontoglossum Pescatorei, which possesses fine shape and a specially broad labellum, if only used once as a breeder, can be traced for many generations in the progeny. Odontoglossum Harryanum asserts its firm substance and peculiar form of markings; Odontoglossum crispum has played an important part in hybrid Odontoglossums, and, through a fine form of O. Wilckeanum, was one of the chief factors in a famous Continental strain.

Cattleya Warneri in any strain gives large size and good shape; Cattleya Gaskelliana is valuable for hybridising; whilst Cattleya Dowiana aurea, the most largely used of all Cattleyas for breeding, has an influence in giving size and colour variation. The past year has brought us many fine yellow-petalled Laelio-Cattleyas, the desired colour being now frequently obtained in the outer segments of the flower, and with the curious result that in yellow-petalled flowers with parents having coloured labellums, the labellums of the resultant hybrids are in some cases much darker than those of either of the parents. On the contrary, certain crosses known to produce frequently white-petalled hybrids invariably also have the labellums toned to a much lighter shade than the parents. Cyanic colours appear to be easily extinguished in certain combinations. These colours appear to be largely floral surface tones, and may be extracted by immersion in water.

Reverting to the list of registered hybrids, some of the crosses should not have been made, as the parents used were too closely allied. Some, again, in the first flowers raised, did not come up to expectation, but it is probable that a large proportion will, on development, prove worthy garden plants, especially as crosses which sometimes do not appear sufficiently distinct often flower at a different time from those they resemble. This is one of the great benefits of Orchid hybridising, for raisers have succeeded not only in giving new and richer colours to their hybrids, but in producing plants that will flower in succession throughout the whole year. It needs a careful selection of parents to avoid those with defective characters in the flowers, for the defects may be handed on as readily as good features; for example, useful as it has been, Laelia purpurata transmits its defective petals for several crossings.

The raising of fine species true from seeds is a field which might be more exploited than it has been up to the present. In the matter of the perpetuation of pure species, of which only a single specimen or a very small number may have been imported, there is a danger that the species may be lost to cultivation, only to be obtained again by chance importation. The raisers of seedling Orchids would do a very desirable work in raising true from seeds small batches of such plants for distribution, a work which might be done in botanic gardens. It will be many years before species of Orchids can be imported as formerly, and home-raising should be practised.

NEW HYBRID ORCHIDS

(Continued from November 24, p. 306.)

Hybrid.	Parentage.	Exhibitor.
Brasso-Laelio-Cattleya Antoinette	C. Portia coerulea × B.-L. Helen	Sir J. Colman.
Brasso-Laelio-Cattleya Anzac var. Vesuvius	B. L. C. Marathon × L.-C. Dominiana	Charlesworth and Co.
Brasso-Laelio-Cattleya Lady Manningham-Buller	B.-C. Digbyano Mossiæ var. Queen Alexandra × L.-C. Ophir	Armstrong and Brown.
Cattleya Achine	Maggie Raphael alba × labiata alba	W. H. St. Quintin, Esq.
Cattleya Adula Dorman	Dormaniana × Adula	Sir J. Colman.
Cattleya Labiatana	labiata × Percivaliana	Duke of Marlborough.
Cattleya Mrs. James Watson	Maggie Raphael alba × Trianæ The Queen	Messrs. Sanders.
Cypripedium Hallwolmer	insigne Harefield Hall × Lord Wolmer	Duke of Marlborough.
Cypripedium Hippolyta	Dante × Hera Euryades	Messrs. Sanders.
Cypripedium John Hartley	Reginald Young × Shogun	John Hartley, Esq.
Cypripedium Mauviridi	Mandine × viridissimum	Duke of Marlborough.
Cypripedium Miss Ruth Bonsall	Actæus Drewett's var. × Miss A. Audrey Locke	Fred J. Hanbury, Esq.
Cypripedium Polinx	Earl of Tankerville × Mr. F. Sander	G. Hamilton Smith, Esq.
Cypripedium Vega	Germaine Opitz × Priam	G. Hamilton Smith, Esq.
Laelio-Cattleya Alecto	L.-C. Ingramii × C. Fabia alba	W. H. St. Quintin, Esq.
Laelio-Cattleya Argo	C. Bowringiana × L.-C. Geo. Woodhams	Baron R. Schröder
Laelio-Cattleya Diana var. Buttercup	Ophir × Jacobus	Armstrong and Brown.
Laelio-Cattleya Empheno	L. C. Prince Leopold × C. Dowiana aurea	W. H. St. Quintin, Esq.
Laelio-Cattleya Haroldensis	Haroldiana × Epicasta	Sir J. Colman.
Laelio-Cattleya Lydaurea	L.-C. Lydia × C. Dowiana aurea	Fred J. Hanbury, Esq.
Laelio-Cattleya Mrs. R. P. Murray	L. pumila × exoniensis × L.-C. Issy	Fred J. Hanbury, Esq.
Laelio-Cattleya Perciclive	C. Percivaliana × L.-C. Clive	Duke of Marlborough.
Laelio-Cattleya Schröderae	L.-C. Bella alba × C. Maggie Raphael alba	Baron R. Schröder.
Laelio-Cattleya Selene	L. C. Fascinator × C. Trianæ	Charlesworth and Co.
Odontioda Hypatia	Odm. ardentissimum × Oda. Diana	Charlesworth and Co.
Odontoglossum General Allenby	crispum nigrescens × hybrid	Flory and Black
Odontoglossum xanthinum	ardentissimum xanthotes × luteo-purpureum Vuylsekeanum	Charlesworth and Co.
Sophro-Cattleya Doreas	S.-C. Dora × C. Dowiana aurea	E. H. Davidson and Co.
Sophro-Laelio-Cattleya L. McKenna	S.-L.-C. Oedipus × C. Dowiana aurea	E. H. Davidson and Co.

TREES AND SHRUBS.

TURKEY OAK AS A PLANTATION TREE

THE good account given by Sir Herbert Maxwell on p. 218 of Quercus cerris is encouraging to intending planters. As a plantation tree it is very rapid in growth, producing clean, straight boles when the side branches are suppressed. It is unfortunate if the timber has been proved unsuitable for outside purposes. It is surprising to learn that Quercus cerris is subject to no disease, although it seems doubtful if it will prove a long liver. I notice here one or two trees starting to die from the top, much after the manner in which Elms often go. Perhaps this Oak needs a lighter soil than the native species; the trees in question are growing on a strong, heavy soil, such as that in which the English Oak often thrives well. Self-sown plants are frequent here. *T. H. Bolas, Mount Stewart, Co. Down.*

BULB GARDEN.

ALBUCA NELSONII.

A POT of bulbs of this species flowered this summer at Holland House, Kensington. It is the finest of the known species of Albuca, and comparable to Galtonia princeps, to which it is closely related. The scapes are not so tall as they could be if the bulbs were of full size, but each bears a raceme of ten to twelve large white flowers, with a dull red stripe down the back of each segment. The bulbs came direct from Nelson, New Zealand, and the name is suggestive, but the species was named after Mr. Nelson, of Broadway, who discovered it in Natal, introduced it to this country and flowered it in 1880. It is a stately plant, carrying its flowers erect, not pendent, as in Galtonia; it belongs to a group including several strong-growing species, and is most nearly allied to A. altissima. It does not require a high temperature under glass to develop in full beauty. There is a full-sized figure of a leaf and flower spike in the *Gardeners' Chronicle* for August 14, 1880, p. 199. *J. F.*

AUTUMN CROCUSES.

"FORMAKIN" (Vol. LXII., p. 212) is unfortunate in having his Autumn Crocuses destroyed by mice and rats. When I observe any signs of mice or rats having attacked my Crocuses, I put a little of Harrison's rat poison on the spot, without any bait whatever, and the mice and rats never return after tasting the poison. This poison is said to be harmless to larger creatures. I think there is less danger of birds or other creatures touching the poison when there is no bread or other bait. *S. Arnott.*

THE DEFERTILISATION OF FLOWERS BY INSECTS.

ALTHOUGH volumes have been written upon the fertilisation of flowers by insects, I do not remember to have seen any statement that insects sometimes cause the defertilisation of flowers by depollinating them.

In June, 1911, I received from South Africa a living plant of Euphorbia gorgonis, Berger, which is one of the succulent species. This plant flowered freely in August of the same year, and I pollinated the stigmas of many of the female flowers with pollen from different parts of the same plant, but no fruit resulted. I was not at all surprised at this result, because I was well aware that many (possibly most) of these succulent species are not fertile to pollen taken from the same plant.

In 1912 the Royal Botanic Gardens, Kew, also became possessed of a plant of the same species, and as my plant and the Kew plant were in flower at the same time I pollinated several stigmas of female flowers that were in a receptive condition upon my plant with pollen taken from the Kew plant, and some of those on the Kew specimen with pollen from mine. The operation was performed with the aid of a pocket lens, so as to make sure that the stigmas were properly dusted with pollen, which I clearly saw adhering to the stigmas. I marked the flowers on my plant that I had pollinated, and the next day examined them with a strong lens to see if I could discover any trace of pollen-tubes. But I could not find the slightest trace of pollen on any of the stigmas. I could only surmise that it might possibly have become deliquescent under the action of the stigmatic juices. No fruit was produced upon my plant. It was only in September last that what I believe to be the right solution was arrived at.

Happening to be looking for a flower of the scarlet Pelargonium that had pollen upon its anthers, for examination under a microscope (it makes a lovely object when properly illuminated), I had found one with two of its anthers covered with pollen, and was wondering why so many of the flowers were destitute of pollen and why only two anthers of this particular flower bore pollen. I also remembered that on some previous occasions I had found Pelargonium flowers destitute of pollen and had thought that their barrenness was due to the effect of hybridisation, when the reason was made plain to me by a fly (one of the pollen-eating Syrphidae) settling upon the Pelargonium-flower. Either it had visited the flower before and knew its details, or it could see at some distance which side of the flower the pollen-bearing anthers were on, for it settled directly by them, and during its stay upon that flower made no attempt whatever to go to the other anthers, which were destitute of pollen. The fly very considerately allowed me to watch its actions with a lens of short focus, so that I could see it rapidly picking up the pollen, and very soon it had cleared every grain off both anthers as clean as if it had never contained any pollen at all. Whilst I was watching the fly eating the pollen from the anthers I noticed that the stigmas of that flower were well dusted with pollen. The fly also perceived that they were pollinated, for as soon as it had finished with the anthers and cleansed its feet of pollen it turned its attention to the stigmas and very soon had picked off every grain of pollen from their surface, thus depollinating the flower and destroying its chance of being fertilised. Having witnessed this, I can now give a shrewd guess as to what happened to the pollen I placed upon the stigma of Euphorbia gorgonis in 1912!

The flies belonging to the family of Syrphidae, I believe, feed largely upon pollen, and doubtless often prevent flowers from being fertilised by eating the pollen that may be upon their stigmas. *N. E. Brown.*

The Week's Work.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

CLIMBERS.—It cannot have escaped notice how climbers and shrubs in general trained to walls become in the course of years a tangle of worthless shoots, frequently intermixed with dead wood. Neglected plants should be cut down close to the ground. Some of them refill their places almost immediately, subsequent to renewal of growth, of which Polygonum baldschuanicum, Piptanthus nepalensis, Menispermum canadense, Vitis Coignetiae, and Buddleia variabilis may be mentioned as examples. Early flowering climbers, such as Forsythia suspensa and Garrya elliptica should be left at present, but the others and many more may be pruned as advised at once. The young shoots for training should be chosen at an early stage of growth, and tied before they become bent, or liable to break.

SURFACE-DRESSING OF VIOLETS.—In many gardens Violets have been neglected, inasmuch as old plantations have not been destroyed and new ones made. A dressing of old potting soil, or the surfacing material of vine borders spread among the plants, will mitigate considerably loss from the above neglect. It does no harm to partly cover the leaves with the topdressing material, for the first heavy rain will wash it off again. Plants of Lily-of-the-Valley may also be given a dressing of similar material, to be followed later by applications of soot, poultry manure, or superphosphate.

THE ROCKERY.—All Alpine plants should be given the usual winter attention, including cleaning, topdressing, the restriction of too robust growers, removal of weeds, stirring of surfaces, rearrangement of stones, and finally an application of light soil sifted to make it suitable to sprinkle among the fine-leaved plants.

HOLLYHOCKS.—Plants of Hollyhock raised from seed sown last autumn should have timely attention in potting, so that the seedlings suffer no check to growth. Give ample pot-room if strong plants are expected to be ready to plant out in April. They should be grown in a temperature of 55° to 60° to induce a rapid growth. There is still time to sow seeds for the present year's flowering in the warmer parts of the country.

SHRUBBERIES.—There may be shrubberies still to clean, and dead wood to cut out of overgrown shrubs as well as shoots to shorten here and there, work which may be done in weather unfit for the carrying out of other operations, and, indeed, one feels that the only reasonable excuse for the upkeep of flower gardens and pleasure grounds in these times is that so very much of the work involved may be done in bad weather.

RELIEVING LABOUR.—Much labour may be saved by laying down beds and borders to grass. By this means I have reduced labour considerably, and still have more beds to put under the lawn mower. It need not be more than a temporary measure to allow for more important work to receive due attention.

WALL ROSES.—Those that need pruning may be pruned at once. The object is to get bloom earlier than if the work were delayed till March, and the best results are obtained from Roses trained on the walls of dwelling-houses and hot houses.

FRAMES.—Beds of cuttings should be examined, and where low, green growth has gained a footing in the surface soil it must be removed and a thin layer of sand sprinkled among the plants. If previously heated, no growth will appear again. Pentstemons and other plants that are rooted should be freely ventilated in suitable weather. The frames may be taken away from Violas and other hardy plants.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

SEASONABLE WORK.—The season for general repotting operations is approaching, and the necessary potting materials should be procured. In recent years Osmunda fibre has been used as a potting medium for most kinds of Orchids with good results, but at the present time it is almost unprocurable, so that a substitute has to be found. Many growers have used A 1 fibre with good results. I have obtained the best success with this material by thoroughly scalding it before cutting it into short lengths, adding an equal proportion of half-decayed Oak leaves that have been rubbed through a rather fine sieve, and a liberal amount of crushed crocks and chopped Sphagnum moss. Treated in this way A 1 fibre forms an economic, pliable, and porous compost. There is no better implement for cutting the fibre than an old chaff cutting machine with one knife removed; where only a small amount is used a pair of ordinary sheep shears will answer the purpose. By the end of the present month the cleansing of the houses should be finished. Each plant should be examined for insect pests, the receptacles washed, and the labels rewritten if necessary.

TEMPERATURES.—During the past season we have employed less fire-heat at Gatton in the warm houses than usual, and the plants seem to have benefited by the treatment. Lath blinds have been drawn over the roof-glass during cold nights, and the atmosphere of the houses kept drier. The night temperatures have been maintained as nearly as possible as follows:—The East Indian or hottest house 60°; Cattleya house 55° to 58°; cool house 50°, with a rise of about 5° in each division during the day. The temperatures have been even lower during very cold nights.

VENTILATING.—The ventilation of the respective houses needs very careful attention at this season of the year. Fresh air in moderation is essential to the well-being of Orchids: a stagnant atmosphere is doubtless one of the principal causes of spot and other diseases in Orchids. Draughts, however, must be rigorously prevented. The bottom ventilators should be opened on the leeward side of the house on all favourable occasions, in volume in accordance with the weather conditions.

WATERING.—The application of water at the roots at this particular season also needs very careful attention. Plants at rest should be given only sufficient moisture to prevent shrivelling, whilst those that are growing actively should be allowed to become dry at the roots before water is again applied.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

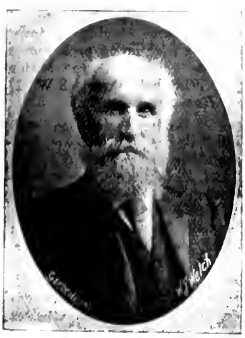
MANAGEMENT OF THE HOUSES.—By the careful use of water, both in regard to watering the plants and the damping down of the houses it is possible to keep the temperatures in all the houses much lower than is generally recommended in normal times. The inmates of the plant stove will not suffer in the least in a temperature of 55° on very cold nights, provided the atmosphere is not overcharged with moisture. The watering of all plants should be done before noon, and it will be safest to err on the dry side rather than over-water the roots. Air should be admitted to the plants by opening the top ventilators a little during the warmest part of the day. The temperature of the houses containing greenhouse plants may go down to 50° or even lower on cold nights. If blinds are attached to the roofs of the houses they should be lowered when severe frost is imminent.

THE FORCING HOUSE. Batches of the various forcing shrubs should be placed in a warm house at regular intervals. It will hasten the process of growth if the plants are syringed with water warmed to a temperature of about 80°. Batches of forcing bulbs may be placed in heat as required. Narcissi which are well rooted may be brought on slowly in any of the cooler houses, and introduced into more heat as required. Lily of the Valley crowns may be dug up in clumps from the permanent beds and placed on a hot bed in a heated pit. Cover them with a little moist sifted soil, and water with warm water. Keep the glass covered with mats or litter till the spikes are about 4 or 5 inches high, then gradually inure them to the light. Water must be given when required, or the flowers will flag.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

FRUIT TREES IN SHRUBBERIES.—In existing conditions the experiment may well be tried of planting standard Apples and Pears in shrubberies. These are not only productive of food, but have at the same time a decidedly ornamental effect. The same may be said of standard Plums, Damsons and Cherries. The aim of the gardener should be at present to produce the maximum quantity of fruit from any given space. However carefully trained trees may appear when denuded of their foliage, if these do not result in good crops the object is not attained. Any vacant wall space should be utilised. It matters not what the aspect may be, some kind of fruit may be chosen for every site, and the roofs of sheds may be covered with fruit trees as well as the sides. If new trees be planted by the middle of March no harm will ensue. Fruit pergolas are not so general as they might be; I have seen many a garden where this feature might be advantageously added, especially in windy or exposed situations.



THE FRUIT ROOM.—In frosty weather care will be needed to see that the fruit-room does not drop in temperature too near to freezing-point: 35° F. should be considered the minimum. The flavour of Pears will be affected by a lower temperature than 40°. I do not advise artificial warmth if it can be avoided. Well-protected sides, double doors, and shuttered windows, will keep out a great deal of frost; failing shutters, protect the windows with mats or sacking. Probably the ideal fruit-room is one which is sunk below the ground, or one that is excavated in the side of a hill. Take advantage of vacant shelves by thinning out the late varieties. Do not let the fruits touch each other if it can be prevented. Be careful in the handling, and take up each fruit separately, so as not to mark it. Take note as to which varieties are keeping best, and reserve these for the latest use. Make a note of them, so as to extend their cultivation either by planting fresh trees or by double grafting. For this latter purpose secure enough good shoots from the prunings for the purpose, and well bed them in moist soil or ashes until the time for grafting arrives. It will now be more essential than ever to take every precaution when packing dessert Pears and Apples, so that no injury is done to them in transit. Forward late Pears towards the ripening stage by placing them in a temperature of from 55° to 60° F.

THE KITCHEN GARDEN.

By J. [illegible], Gardener to the Hon. [illegible] SPENCER [illegible], M.P., Wormleighton, Southam.

FORCING ASPARAGUS. No vegetable is more appreciated than Asparagus, and it is one of the easiest to force. Forcing of late crowns is the only method of forcing early Asparagus during the winter. Any heated pit containing a good lasting bottom of leaves should be composed chiefly of leaves, and covered with about six inches of soil, will answer the purpose. Place the roots closely together and force them in a temperature of 55° to 60°; the lower the temperature in reason the better will be the "grass." To provide the necessary roots the plants may be lifted from an old bed or two, and preparations must be made to have fresh beds to take their places.

THE SEED ORDER. The seed catalogues are being received from the various firms, and the order for such as are required should be dispatched in good time, as all business staffs are depleted, and those who delay sending may receive their seeds very late. Novelties in vegetables appear each season in most seedsmen's catalogues, and a few of the more promising new varieties should be given a trial in small quantities.

GENERAL REMARKS.—The weather during the past month has not been favourable for preparing the ground for next year's crops. Continued falls of snow and rain have made the carting and wheeling of manure on the ground an almost impossible task. Advantage should be taken of every frosty morning to push this work forward using all available labour for the time being. Ground that is to be trenched this spring should be spread with manure and other fertilising materials, such as burnt refuse and soil from old hot beds. This work may be done during frosty weather, but on no account when the ground is covered with snow. Previous arrangements having been completed for the rotation of crops, the ground should be heavily or lightly dressed with manure, according to the requirements of the individual crop. Ground intended for Onions, if not already prepared, should be attended to at once. Select an open situation and dress the soil liberally with manure. Dig deeply, and as soon as convenient, to allow as much time as possible for the soil to become well pulverised before sowing time arrives.

FRUITS UNDER GLASS.

By W. J. GOSS, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

STRAWBERRIES.—Where a pit is available it may be utilised for the first batch of Strawberry plants, and, if filled with leaves, will provide sufficient warmth to promote root action. Before arranging the plants they should be looked over, all dead and decaying leaves removed, and the surface top-dressed with a loamy compost containing a little fertiliser and soot. Air should be freely admitted; very little water will be required till the plants are making fresh foliage, when it must be given more frequently, always with the chill off. Directly the flower spikes appear remove the plants to a shelf in an early Peach house, where the temperature does not exceed 55°. Spray the foliage with tepid water during bright weather. Where the plants are placed in houses from outside, a temperature of 45° will be sufficient until the flower spikes appear.

FORCING.—The scarcity of fuel, coupled with the difficulty of obtaining labour, makes it necessary to curtail the forcing of fruits. Cleaning should be completed by thoroughly washing every portion of woodwork and glass with carbolic soap. Fresh lime should always be used to limewash the walls where red spider has been troublesome. The pruning and cleansing of the trees should be pushed forward. It is essential that Peach trees should be pruned and trained before the buds are further advanced. The growths should be thinned out so as to leave only sufficient shoots to lay in at 4 inches apart. Remove the old top-dressings from the borders and replace with a fresh compost. The water pipes are much improved in appearance by a coating of lamp-black. See that all valves and boilers are in working order.

LATE VINERIES.—By this time the latest Grapes should be cut. Place the bunches in bottles in a dry room where the temperature is even and low. Lady Downe's and Black Alicante will retain their appearance for a considerable time in such a structure. A few pieces of charcoal placed in the bottles will keep the water sweet. The vineries will then be ready for cleansing operations. Pruning may be carried out immediately afterwards. Do not prune old vines too closely, but only to the best round, plump bud at the base, which in most cases contains an embryo inflorescence. Thoroughly wash the rods with an insecticide, and remove all loose bark. Examine the borders for young surface roots, and should these be absent or in an indifferent condition, remove the soil down to the main roots, and replace with fresh chopped turfy loam. Cover the rougher material with a few inches of a finer compost, and finish off with a dressing of short manure. All borders, if at all dry, should be thoroughly soaked with clear water, and the houses kept cold and freely ventilated until required for starting.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41 Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.0.

ACTUAL TEMPERATURE:—*Gardeners' Chronicle* Office, 41, Wellington Street, Covent Garden, London, *Thursday*, January 3, 10 a.m.: Bar. 30; temp. 35.5°. Weather—Fine.

A National Rose Garden for America.

The American Rose Society Test Garden Committee has recently issued a pamphlet describing the National Rose Test Garden proposed to be established under the direction of the Bureau of Parks of the City of Portland, Oregon, and under the auspices of the Portland National Rose Test Garden Association. The pamphlet states that this garden has been officially designated by the American Rose Society as the testing ground of that Society for the Pacific North-West, and that all awards made in connection with the garden will be recognised by the American Rose Society.

When fully developed the garden will cover 7 acres or more, as the Bureau of Parks has arranged for an expanding policy, and in choosing the site all conditions which enter into the successful cultivation of the Rose have been duly considered. The position decided upon, though within 15 minutes of the business centre of the city, commands a view of the city itself, the rivers, and a wonderful panorama of the Cascade Mountains, with their peaks, covered with eternal snow, some 60 to 80 miles distant; while the terraces on which the garden is to lie are situated in a natural amphitheatre of hills with an exposure ranging from north-east to south-west, thus receiving protection from winds.

The American Rose Society is youthful and vigorous, and has the advantage of being able to draw on the experience of the older societies of England and France and to adopt and develop the enterprise of each. From the former it has taken the idea of a Rose Annual, the first number of which we welcomed last year, while from the French Society, it has doubtless taken into consideration the well-known Rose trials at Bagatelle, and proceeded to the enterprise we are noticing.

In one respect, the method of making awards proposed by the American Society must be considered a great advance on the methods adopted in Europe. Both the English and French awards to new Roses are made to flowers or plants considered by the judges to be of sufficient merit, irrespective of their competitors. The comparison the judge has to make is not between two exhibits before his eyes, but between the plant or flower he is inspecting and some ideal in his own mind. It is small wonder that so faulty a system leads to criticism, and that the value of the awards so made has come to be regarded as unsubstantial and ephemeral.

It is greatly to the credit of the American Society that it has had the courage to abandon this system, and strike out a line of its own.

The Roses to be tested are to be entered in one or more of five sections, and first and second prizes are to be awarded to the best Roses in each section. Thus the comparison to be made by the judges is between plants actually before their eyes, and we may feel some confidence that the results will prove of practical value.

The difference between the two systems is not unlike that between the syllogistic idealism of Plato and the new philosophy of Francis Bacon, between the flower and the fruit, between barren learning and practical utility, the logic of the schoolmen and the advance of science. The American awards will have a definite value. It is what we might expect from so practical a nation, and makes for the useful development of the Rose.

All Roses submitted are intended to be tested in threes. One will be placed in the natural soil of the garden, treated only with manure, and another in soil specially treated with commercial fertiliser. In both these cases the plants are to be sprayed and treated in every manner necessary to resist mildew, black spot, and other diseases, and they will also be carefully protected from insect pests. The third plant in each case will be given ordinary garden cultivation, but will be unsprayed, the tests in this section being designed solely to ascertain the disease-resisting qualities of the plant. This section of the garden is to be sufficiently far removed from the other sections to prevent contamination of those plants which are being tested for other qualities.

In forming the prize list, the only differentiation at present adopted is between climbing and non-climbing varieties. Thus the first section is general, the second section for the best non-climbing Rose, the third for the best climber, the fourth for the best Rose raised by an amateur, and the fifth for Roses of local origin. If the enterprise succeeds, we may hope in future years to see this differentiation carried a step further, and classes developed for exhibition and decorative flowers, Polyantha, Pompon, and other sections, and thus there may gradually grow up a classification of Roses simply for garden purposes, capable of taking its place side by side with the existing system of classification.

Roses are allowed by the regulations to be entered under names or numbers. While this in itself may not be unreasonable, it is much to be hoped that a further regulation may be added requiring every successful competitor to give to his plant, if exhibited under a number, a proper name before it is eligible to receive an award, and thus to avoid the uninteresting experience annually awaiting the visitor to our Daffodil shows, where beautiful flowers are staged under numbers only, which it soon becomes impracticable to remember or to notice.

When Roses are entered for trial at Bagatelle there is a useful rule, though perhaps not sufficiently strictly enforced, requiring the parentage to be stated, a feature which adds to the interest of the trials. The American Society appears to have made no provision to this effect, and it may be worth consideration whether in subsequent tests the omission should not be made good.

These, however, are points of minor importance, and do not detract from the pleasure with which we welcome this new enterprise of American Rose-growers.

OUR ALMANAC.—The *Gardeners' Chronicle* Almanac will be published as a supplement to the issue for next week.

HORTICULTURAL CLUB.—The difficulty respecting the provision of fresh headquarters for the Horticultural Club since the Hotel Windsor was taken over by the Government has been met by an arrangement recently concluded with the Farmers' Club, whose rooms are at 2, Whitehall Court, S.W. I. By this arrangement members of the Horticultural Club may use the rooms of the Farmers' Club freely and with all privileges. Whitehall Court is situated exactly at the rear of the War Office, which is almost opposite the Horse Guards, so the rooms are easily reached from Victoria Street, Westminster. The Club premises are on the second floor, and this is reached by means of a lift which will be found on the right upon entering 2, Whitehall Court. Refreshments can be ordered in the Club rooms, and there are luncheon and dining rooms in the building, so that Whitehall Court has all the advantages of a first-class hotel. Members staying in town for a night or more and wishing to book rooms should address their enquiries to Major HORNSBY, Manager, Whitehall Court, S.W. 1. *R. Hooper Pearson, Hon. Sec.*

SIR DANIEL HALL.—Horticulturists as well as agriculturists will welcome with pleasure and satisfaction the announcement that a K.C.B. has been conferred on Mr. A. D. HALL, Secretary to the Board of Agriculture. Sir DANIEL HALL has had a long and distinguished connection with agriculture, at Wye and Rothamsted, and as a Development Commissioner. One of the most versatile of men, he possesses the secret of combining thoroughness with variety of knowledge. Although professionally and whole-heartedly devoted to agriculture, Sir DANIEL has nevertheless found time to become an expert horticulturist, and there is probably no amateur living who can rival him in his knowledge of Tulips. His work on the soil is a masterly book—one of the few text-books in the language which it is a pleasure

as well as a profit to the grower. *Pilgrimage of British Farming* shows the same qualities of grace and power.

CARNATION MARION WILSON (see fig. 6).—The Perpetual flowering Carnation Marion Wilson is a distinct variety which is likely to find favour with growers of this type. The flower measures nearly 3½ inches across. In addition to large size it is possessed of stout substance. The form is not so regular as in some sorts, but perfect symmetry is not so desirable a quality for the florist's purpose as boldness and a striking colour, so that for market purposes the variety will doubtless become popular. The general tone is pale yellow, with a few vermilion markings here and there on the petals. Plants grown out of doors have flowered freely, and the foliage is not browned by the sun, as sometimes happens in the case of other yellow Carnations of the same type. Cut blooms were shown at the R.H.S. meeting on December 4 when the Floral Committee gave the variety an Award of Merit and these lasted fresh for nearly a fortnight.

PROFESSOR HUGO DE VRIES.—On February 16 of the present year Dr. Hugo de Vries will have completed his 70th year, and will, in accordance with Dutch law, retire from his professorship in the University of Amsterdam. Recognising the great and distinguished services which DE VRIES has rendered to botanical science, and particularly to the science of plant breeding, his colleagues in Holland have decided to publish in book form in his honour the collected essays of DE VRIES. Recognising that his work is known and valued in all parts of the world, the Dutch committee formed to carry out this project invite subscriptions from all parts of the world. The contemplated work will consist of six volumes, each of 550 pages, and the publication will extend over three years. The subscription, of 45 florins, may be paid in three annual instalments, and should be sent to the secretary, Prof. Dr. Th. H. Stomps, Weesperzijde 23, Amsterdam.

MOLES.—Among the minor effects of the war are the increase in numbers of such animals as rabbits and moles. The multiplication of the numbers of moles is likely to have curious consequences, for moles are voracious feeders. According to observations made by Miss FRANCIS PITT, and recorded in the *Scottish Naturalist* for September, a mole will eat its own weight of earthworms in 24 hours. A mole weighing 4 ozs. kept in captivity by Miss PITT ate in one month 7½ lbs. of earthworms.

BEQUEST TO A GARDENER.—It is reported that Mrs. S. A. PATTISON, of Knightsbridge, London, lately deceased, left a thousand pounds to her former gardener, Mr. JAMES NORRIS.

BRITISH ROSE GAINS AN AWARD IN AMERICA.—Messrs. DOBBIE AND CO. have been awarded a Silver Medal and Diploma for a new Rose sent for trial to the Panama Pacific Exposition, San Francisco, 1915. The Executive reserved the right to name all seedlings that obtained awards, and it has named Messrs. Dobbie's variety the Thomson Rose. In forwarding the Diploma, the British Embassy at Washington states that the delay in making the announcement is due to the fact that the authorities concerned had hitherto feared to send the Diplomas, etc., across the Atlantic for fear they might be destroyed, and that it would be impossible to replace them. The Thomson Rose is an improved Mrs. F. Straker, and is very floriferous. It will probably be put into commerce in the autumn of 1919.

HORTICULTURE IN AMERICA.—An old correspondent of the *Gardeners' Chronicle*, referring to the influence of the war on gardening in America, writes us as follows: "The coming year may be hard on horticulture in America. We are feeling certain effects at this time, due to decreased importations. The Dutch bulb situation is very disconcerting, but I feel that the total result will be to the great benefit of American horticulture. Hitherto the trade has lagged behind the demand, preferring to sell only those things which could be bought in Europe at a price lower than they could be propagated in America. The result has often been the distribution of quantities of material that did not actually fit the climate of America, where the greatest amount of gardening was done. You can interchange the European material with the Pacific Coast but not generally with the East. So, I think that the ultimate result will be to the benefit of American gardens, because they will have to develop their own materials and rely on their supplies more on the things that actually fit."

FIG. 6.—CARNATION MARION WILSON: COLOUR YELLOW, WITH VERMILION STRIPES.

THE MARKETING OF CUT FLOWERS.—An interesting article on the treatment of cut flowers for marketing was read by Mr. WM. COLLIER at the 20th annual convention of the Canadian Horticultural Association at Montreal. The great attention paid by North American florists to the preparation of cut flowers for the market is no doubt in part due to the long distances over which the blooms have to be carried; nevertheless the fact that the care bestowed on the flowers is apparently repaid by results indicates that it should be worth the while of florists in this country to try similar methods. American Rose growers, for example, regulate the daily cutting of blooms according to weather conditions, and make a strong point of transferring the blossoms without delay to "coolers" or refrigerators kept at a temperature of from 38°-40°. The object is to "harden" the blossoms, and to secure the accomplishment of this object the cut flowers are left for 12—or, in the case of Roses, preferably 24 hours—in the cooling chamber, after which the blossoms are graded. Chrysanthemums, Lilies, and other cut flowers are treated in a similar manner, but in the case of Carnations some growers prefer to harden the blossoms in a temperature somewhat higher than that to which Roses are exposed. Mr. COLLIER holds the view that even those growers who have markets near at hand will find it pay to harden off their cut flowers before marketing them, for the superior lasting qualities of blossoms so

THE MARKETING OF CUT FLOWERS.—An interesting article on the treatment of cut flowers for marketing was read by Mr. WM. COLLIER at the 20th annual convention of the Canadian Horticultural Association at Montreal. The great attention paid by North American florists to the preparation of cut flowers for the market is no doubt in part due to the long distances over which the blooms have to be carried; nevertheless the fact that the care bestowed on the flowers is apparently repaid by results indicates that it should be worth the while of florists in this country to try similar methods. American Rose growers, for example, regulate the daily cutting of blooms according to weather conditions, and make a strong point of transferring the blossoms without delay to "coolers" or refrigerators kept at a temperature of from 38°-40°. The object is to "harden" the blossoms, and to secure the accomplishment of this object the cut flowers are left for 12—or, in the case of Roses, preferably 24 hours—in the cooling chamber, after which the blossoms are graded. Chrysanthemums, Lilies, and other cut flowers are treated in a similar manner, but in the case of Carnations some growers prefer to harden the blossoms in a temperature somewhat higher than that to which Roses are exposed. Mr. COLLIER holds the view that even those growers who have markets near at hand will find it pay to harden off their cut flowers before marketing them, for the superior lasting qualities of blossoms so hardened will make the produce more acceptable to the market. Flowers such as Sweet Peas and Violets require, however, if they are to arrive at the market in the best condition, to be despatched as soon after picking as is possible.

WAR ITEM.—Private J. HUMBLE, formerly employed in the gardens of Stourton Hall, Kinver, Staffordshire, has been killed in action. He was the youngest of six brothers serving with the Colours.

MR. R. A. ROLFE AND THE "ORCHID REVIEW."—The receipt of the issue of the *Orchid Review* for November-December, 1917, reminds us that it completes the 25th volume of this useful periodical. Some four older readers

will remember the circumstances which prevailed at the time of its promotion. REICHENBACH had left instructions that his herbarium in Berlin was not to be opened until twenty-five years after his death. He had for many years occupied the position of botanical botanist for Orchids, and to him English and Continental cultivators had sent their specimens with a view to the spread of accurate knowledge concerning classification. On REICHENBACH's death in 1889, disappointment regarding the locked-up treasures of his herbarium was general. We ourselves wrote: "It would be affectation to pretend that we did not receive the announcement we have to make with chagrin and sorrow. The task of Orchidists in this country is by this action rendered peculiarly laborious and perplexing." For a period there was some doubt as to who would take up the work which had ceased with REICHENBACH's death, but eventually by the devotion of Mr. R. A. ROLFE to the study of Orchids at Kew, and later by the establishment of the *Orchid Review*, all was done that was possible to help forward the cultivation of Orchids in this country, and to maintain the interest of those engaged in raising new hybrids. It is only those most intimately associated with the Editor and the plants treated upon in his journal, who know the difficulties he had to overcome for some years. Indeed, throughout the whole period the task of keeping the *Review* up to the high level it attained has been considerable. At the present time, when the mind and energies of the nation are mainly directed to other matters than Orchid cultivation, this pursuit does not loom so largely as it has done in past years. But collections must be maintained, even in such a period as that through which we are now passing, for the named hybrids and the many thousands of as yet unnamed seedlings represent a sum of energy which must not be wastefully thrown away. It is satisfactory, therefore, to know that in spite of the difficulties connected with the printing of journals, the *Orchid Review* is to be continued, and we hope that with the resumption of peace it will enter upon a period of increased success.

NOTES FROM AMERICAN JOURNALS.

INVENTORY OF IMPORTED SEEDS AND PLANTS.

In his preface to the Inventory of seeds and plants imported into the United States during the period from January 1 to March 31, 1914, Mr. David Fairchild draws attention to a number of interesting and promising plants. Among the former is the Kerruelen Cabbage, Pringlea antiscorbutica—familiar, at all events by name, to readers of Darwin's *Voyage of the Beagle*. It is a low sprawling plant, bearing heads of leaves sometimes 18 inches across, and with a dense white heart with a taste like Mustard and Cress.

Phaseolus aureus is a Chinese Bean from which the Chinese produce a starch said to be superior to that yielded by either Maize or Wheat.

The several varieties of Flax from Addis Ababa, Abyssinia, should be of interest to Flax growers of this country, particularly at the present time when there is need for a considerable extension of the area under this crop.

LIMESTONE.

According to experiments made by Mr. N. Kortlieff at Rutgers College, New Jersey, the value of ground limestone increases with the degree of fineness to which it is ground. Ground so finely as to pass through sieves with 200 meshes to the inch limestone is said in its soil effects to burn lime.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CUPRESSUS FORMOSENSIS. Mr. H. White, Sunningdale Nurseries, Windlesham, has sent me two nice plants of this species, which he raised from seeds received from F. R. S. Balfour, Esq. Mr. White tells me that though the thermometer in the Sunningdale nurseries went down to zero twice during last winter, C. formosensis was not injured. I must therefore suppose that the death of my own plant, recently recorded in the *Gardeners' Chronicle*, was due to soil rather than climatic conditions, as the Giant Cypress of Formosa has proved hardy also at Monreith, where I saw it recently.—*H. J. Elwes.*

SUGAR FROM SUGAR BEET.—I grew last season a small quantity of Sugar Beet in these gardens, and the cook succeeded in making syrup and sugar, both of which are good. She has given me the recipe and particulars, which are as follow:—Boil the Sugar Beet as in the case of ordinary Beet. When cold, peel the roots and cut them into slices; put into a pan, and cover with clean cold water. Place the pan on the stove, and let the contents simmer for ten hours. Strain, and afterwards boil the liquid down, from about one gallon to half a pint. This will give syrup. For sugar, boil down still and when cold pound the mass in a mortar.—*W. Fisher, Effects Gardens, Killarney.*

GROUND OPERATIONS.—Mr. C. Davis quotes me (p. 262, Vol. LXII., to give my experience on the subject of digging. In my opinion the right method is to trench all light ground, so far as is possible, during the autumn, but land of a very heavy, tenacious character is much better left undisturbed until the new year. Towards the end of February is the ideal period for digging such heavy ground. I have always found that trenching very heavy land in autumn means that after falls of rain and snow the soil again becomes solidified, and it is in anything but a proper condition for the planting and sowing of crops, and especially root vegetables. I am fully alive to the fact that during this period of shortage of labour work cannot always be done at the proper time; nevertheless, the fact remains. In these gardens we are unable to practise trenching to the same extent as in former years, but fortunately the whole of our kitchen gardens had been trenched and retrenched in previous years, so that the necessity for deep cultivation is not so urgent as on gardens where the system has not been practised.—*Edwin Beckett, All Saints' House, Gardens, Hertfordshire.*

STORING APPLES.—How to keep Apples satisfactorily is indeed to the attention of fruit growers for many years past, and good advice has been offered widely on many occasions, yet it is surprising the number of people who are still ignorant of even the most elementary rules governing the keeping of fruit. For some reason or another, far too many hold the opinion that the fruit should be stored in a dry, airy room, and even go as far as to have open lattice work for shelves, which is absolutely wrong. Again, they take the greatest care that the fruits should be laid on singly, until, more than instead of the fruit keeping fresh and plump, they soon shrivel and the decay naturally intensifies. The ideal place is a well-designed, frost, rat and mouse-proof fruit room, and where even a small quantity of fruit has to be stored, it is well worth the outlay and trouble to erect. At Aldenham we never hesitate to pile the fruits one on top of another, even to six or seven layers, but it is essential to handle the fruit very carefully in all ways and sorting, always selecting any which show the slightest blemish. The cooler the temperature provided it is kept above freezing, the better. If by chance one finds a diseased Apple in mid-winter, as I have on many occasions, which has been covered with leaves, it is beautifully fresh and plump.—*Edwin Beckett.*

Obituary.

ANDREW CAMPBELL.—The death of Mr. Andrew Campbell, gardener to Lady Ardilaun, St. Anne's, Clontarf, Dublin, is a severe loss to Irish gardening. He came to St. Anne's as a boy in 1869, and, with the exception of a few years when he went to Muckross, Killarney, to improve his knowledge and to gain further experience, he passed the remainder of his life in the service of the Ardilaun family, partly as foreman at St. Anne's, later as head gardener in Lord Ardilaun's estate in the West of Ireland, Ashford, Co. Galway, and from 1895 as head at St. Anne's. It is chiefly in this last-named place that he made his reputation as an accomplished and tasteful gardener. He took a keen interest in all that concerned the progress and welfare of gardening, giving lectures and demonstrations to young gardeners, judging at shows, and encouraging and helping various societies and associations. His skill extended to all branches of gardening, both indoor and outdoor, and his name will always be associated with the fine varieties of Lobelia, Anemone japonica, and other plants raised by him.

WILLIAM FROMOW.—By the death of Mr. William Fromow, at Chiswick, on December 30, the horticultural trade loses a well-known London member. The nursery and seed business, which has branches at Chiswick, Hounslow, Windlesham, and Bagshot, was established in 1829 by deceased's grandfather. Until recently the firm consisted of three members, Messrs. Joseph, Edwin, and William Fromow. Deceased, who was aged 65, leaves a widow, one daughter, and three sons.

JOHN M. DOW.—The death took place, on the 12th ult., of Mr. John M. Dow, a well-known nurseryman and seedsman, of Falkirk. He succeeded his father in the business, which was established in 1826, and carried it on until recently under the name of David Dow and Son. Mr. Dow, who was 79 years of age, was for a long time treasurer of the Falkirk Horticultural Society.

JOHN SMITH.—We regret to record the death of Mr. John Smith, Fern Cottage, Well Street, Monifieth, at the age of 88 years. He was a native of Dundee, but spent the greater part of his life in Monifieth, where, previous to his retirement over twenty years ago, he was employed as head gardener in the Fountainbraw Nurseries of Messrs. W. P. Laird and Sinclair, Ltd.

ALEXANDER MCALLISTER. The *American Florist* records the death of Mr. Alexander McAllister, formerly a florist at Passaic, U.S.A. Mr. McAllister was a native of North Ireland. He settled in America with his parents when five years of age.

G. SCOTT.—We regret to announce the death of Mr. G. Scott, nurseryman, seedsman, and florist, of Ellesmere. Mr. Scott, who was a septuagenarian, was found dead in the 26th ult., in a greenhouse adjoining his residence.

JOSEPH BURTON.—Mr. Joseph Burton, Superintendent of the Public Parks, Leicester, died at the Abbey Park, Leicester, on the 14th inst., at the advanced age of 81 years. Mr. Burton was born at Flitwick, Bedfordshire, and began his career in the gardens of Major Brooks in that district. Later he was appointed foreman in a nursery at Huddesden, where he became associated with the late Mr. Gordon. In 1854 he removed to Leicester, and gained further experience at Messrs. Warner's Abbey Nursery. Subsequently he was appointed gardener to the late Mr. Charles Nixon, Stonygate, Leicester. He was a prominent member of the old Leicestershire Horticultural Society, and won a large number of prizes at exhibitions. In March, 1882, he accepted the appointment by the Leicester Corporation as foreman gardener, previous to the opening of the Abbey Park, and in 1892 he was appointed successor to the late Mr. John Burns as Superintendent of the Public Parks and the Recreation Grounds. He also had charge of the arrangements of the annual Abbey Park Flower Show.

ON INCREASED FOOD PRODUCTION.

POTATO SIR JOHN LLEWELYN.

IN reply to *T. N. B.* (Vol. LXII., p. 216) I may say that I have not yet tried the Sir John Llewelyn variety. Considering that it has seventeen years to its credit, I am surprised to learn that it still remains so free from disease. The large tubers and smooth white skin are suggestive of attack sooner rather than later. No doubt its earliness is a great shield against the late blight (Phytophthora), but I imagine that the nature of the soil has also much to do with relative freedom from disease. If *T. N. B.'s* soil is alluvium, or on chalk, that would account to some extent for successful results, by limiting the size of the tubers, contributing to the production of starch and general good quality, as well as warding off disease. Several varieties last year, in my experience, were attacked by disease that was not late blight, and that, too, in light soil. That Sir John Llewelyn should keep so well in a house is also surprising. Witch Hill, Epicure, British Queen, and some others kept in doors began sprouting some time ago.—*J. F.*

PROTECTING POTATOS.

THE great shortage of Potatos last winter and spring will long be remembered, and this was due to many causes, but one, and that a very important one, was, I am certain, not recognised by the majority. Many stores of Potatos were unfortunately frozen owing to lack of adequate protection. The majority of the holders of such stocks were content to rely upon the protection used during mild winters and applied no further covering when the sharp snap of frost visited us, with the result that the tubers were frozen and rendered worthless. This occurred alike to small and big holders, both in buildings and where clamped in the open, as well as the many tons lost by the hundreds stored during transit. It is to be hoped that the experience of the many will render them all the more careful to take precautions against such happenings this year, and a word of advice as to this, in case of a sharp spell of severe weather, may not be out of place at this season. In view of the great value of the Potato as food in these troublesome times, I am convinced that warning against a repetition of last year's disaster can hardly be made too public.—*E. Beckett.*

CABBAGE "SUTTON'S HARBINGER."

DURING the past few years I have grown as many varieties of Cabbage as possible with a view to testing the earliest to mature. I have to confess to in saying that "Harbinger" is well ahead of any other sort I know. Seed was sown July 27 last was germinated in skeleton frames and the seedlings planted out on a south border on September 1, at a distance of 1 foot 6 inches between the rows and 1 foot from plant to plant. So early as the middle of December fully 25 per cent. were ready for cutting, and the others are coming in rapidly. The stock is apparently correctly true, so far as I am able to detect, with not a semblance of a rogue amongst them. Later batches of the same variety are equally promising.—*E. Beckett.*

FORCING VEGETABLES.

THE forcing of vegetables on hot beds is to be encouraged in these times of food scarcity, and in places where large quantities of fallen tree leaves are available a supply should be obtained for mixing with stable litter, and the heap turned two or three times. If stable dung is not available leaves may be used by themselves for making hot beds. Stake out a piece of ground the length of the frame, and make the hot bed 2 feet wider than the frame at the back and front. Spread the hot-bed material evenly and tread it firmly until the heap is about 5 feet high. The higher the bed and the firmer it is made the more lasting will be the heat. When the bed has settled down a little fill up uneven spaces and place the frames in position. Place some rough material in the bottom of the frame. A stake should be plunged into the fermenting material, and when the heat of fermentation is declining three parts fill the frame with soil. Old potting soil mixed with loam and old hot bed manure make an ideal compost for nearly all kinds of vegetables. The materials should be thoroughly mixed. Let the lights be tilted at the back to allow superfluous heat and moisture to escape.

POTATOS.—If it is intended to force Potatos seed tubers of an early variety should, in the meantime, be sprouted in trays. When the growths are about half an inch long the tubers are ready for planting. The frames need not contain quite so much soil as for smaller growing vegetables, and this will permit of space for subsequent dressing. Plant the tubers with a trowel about 15 inches apart, and cover them with about 2 inches of soil. Admit a little air to the frame in the daytime, but close it early in the afternoon. As the shoots develop admit more air to promote sturdy growth. Protect the frames at night in frosty weather with garden mats. When moisture is needed at the roots use water from a tank in a warm greenhouse, and apply it in the mornings. When the shoots are 5 or 6 inches high the plants should be earthed up, placing the soil carefully between the rows, and watering it with a rose can. The crop will not need much more attention beyond ventilation. On favourable occasions the lights should be removed entirely. If the frame touches the glass, lift the frame up with a crowbar placed under bricks at each corner, and arrange some more hot bed material round to keep the warmth in. I grew Midlothian Early last year on this system, and also on beds in a greenhouse, but had much the best results from frames on hot-beds.

CARROTS AND TURNIPS.—Selected early maturing varieties of both Carrots and Turnips force readily, and give delicious roots for the table. The soil should be sifted through a ¼-inch sieve and the frame almost filled with it. In a day or two the soil will sink a few inches, and should then be raked over and the seed sown in drills 6 inches apart. Cover the seed with fine soil to a depth of half an inch. Water with tepid water through a fine rosed can, and close the frame. See that the frame does not become too warm, and if there is a danger of this direct it admit a little air. When the seedlings have made rough leaves thin them out sparingly, and sprinkle a little fresh soil along the rows. Do not over-water the plants, moisture arising from the hot bed will suffice while the plants are small, but direct watering may be needed as the size increases in power. The lights may be removed on warm days.

LETTUCE.—It is extraordinary the rate at which Lettuces grow in frames on hot beds. It is best to raise the plants in a warm greenhouse, and when they are large enough to handle transplant them to the prepared frames at about 9 inches apart for the Tom Thumb varieties and a little more for the larger sorts. We rely on the variety Commodore Nutt for our earliest supplies. The flavour is good, and the plants stand well. Lettuces may also be forced in greenhouses as they do not require much soil, but in too much warmth they will become infested with green fly. The roots should never be allowed to become dry or the leaves will have a bitter taste.

RADISHES.—Radishes have not the same food value as Potatos or Carrots, Turnips, or Beet, but they may be forced quickly. Some growers sow a few Radish seeds amongst other vegetables in frames, and this practice answers very well. Small growing varieties are used, as the roots mature in about three weeks, and the plants have to be cleared off. But as a rule they do better by themselves, as they will start quicker at and moisture than most vegetables. Give the roots plenty of water or they will be [illegible]. *R. W. Thatcher, Carlton Park Gardens, Maidenhead Harborough.*

CONTINUOUS CROPPING OF VEGETABLES ON THE SAME SITE.

THE question of rotation or successive cropping, as indicated by C. Turner (p. 247), is one which opens up a wide field for observation, speculation, and practical experiment. Happily, we have many data in the past upon which we can lean and take as a guide for future experiment. I accept all that he has quoted from the text books as perfectly correct from their standpoint. There is a great difference, however, between spade culture and agriculture. Good land is a mine of plant food if properly worked. When a crop of vegetables is taken off garden ground, it usually means that roots, stems and leaves are removed. This has to be made good in the form of manure, and by trenching, hoeing, and giving other good cultural treatment to enable the soil to contribute its fresh quota of plant food. On the farm this cannot be done; hence the necessity for rotation cropping in order to economise the plant foods in the soil. The land is very shallowly ploughed, and subsoiling is not general. Only the straw and the excrements of domestic animals are returned to the land, with the addition of artificial manures for certain crops; but this is altogether inadequate to restore the fertility of the land without a rotation of crops. A farm of good rotation with which I am familiar would run as follows. First year after grass, Corn; second year, Swedes, Turnips, or Potatos; third year, Corn with grass and Clover seeds; fourth and fifth years, Hay or pasture. On fertile land a second crop of Corn, Yavel is often taken off after grass, but it is seldom, if ever, so good as the first, showing that the fertility of the land has been reduced by the exhausting crop of grain.—*J. F.*

GROUND OPERATIONS.

THE words of your able correspondent, Sir Herbert Maxwell, in his concluding article on "Notes from a Galloway Garden" (p. 255), "It is from records of experience and observation under various conditions of soil and climate that we make progress in the craft," apply especially to ground operations. My policy is to dig in dry weather, not when it is raining, snowing, or freezing, and to dig a portion of the ground extra deep every year. We have had two months of ideal weather for all outside work; planting, pruning, training, cleaning, and protecting trees and bushes. My soil is light, with a gravel subsoil. The ground, which was cropped with Peas, Runner and French Beans, Autumn Cauliflower, Broccoli, Carrots, and Beet, has been dug two spits deep, and that for Onions three spits deep, adding a liberal quantity of manure.

The recent frosts have made the soil like powder, and it is ready for sowing in January and February with Broad Beans, Peas, Parsnips and Spinach. There is another account of the subject. Broccoli, Leeks, Celery, Brussels Sprouts, Kale and Savoys still [illegible] Asparagus in the kitchen garden should be dug [illegible]. I have had many loads of [illegible] decayed [illegible] and I prefer it to [illegible] I use [illegible] manure all round [illegible] manure [illegible] for the Potatos. A [illegible] manure [illegible] for the Potatos.—*Japonica.*

CROPS AND STOCK ON THE HOME FARM.

NEED FOR AN INCREASE OF CEREALS.

IN writing my first article for the New Year I desire to make a strong appeal to landowners, farmers, agents, and all who have any control of land, to add to the existing area of arable soil by ploughing up fresh grass-land. There is a likelihood of a shortage of cereal foods generally, and if we once allow the stocks of grain to be depleted it will be a long time before they are satisfactorily replenished. Apart from the national necessity, I can say from a personal point of view that much grass land in the country would be more productive if it were under the plough than it is at present. As a member of an advisory committee whose object it is to increase the arable land by 2,000 acres for cereal crops from a total of 37,261 acres in this area, I have ample opportunities for seeing that under their present tillage many fields yield to the occupier far too little in proportion to what such land ought to produce under cultivation.

I am afraid there are individuals who lack the energy necessary to make the most of their land, and there appears to be a want of knowledge of the fact that many fields now producing little ought to be made more productive.

An excuse I often hear is, "If I break up that pasture, imagine how many years it will take to replace it." This line of argument has little justification, as, under correct treatment, a good grass plot can be produced in a few years. Too many of the so-called pastures are only pastures in name. Instead of being prepared and sown with selected grasses, they were allowed to "fall down" to grass from an exhausted Sainfoin or Clover ley which had all too often become overrun with obnoxious weeds, and so long as the field was green and produced something it was called a pasture.

It is such examples as these that should be ploughed and made to produce their share of cereals. Where a pasture produces desirable grass for cows and crops of Hay of not less than 1½ ton per acre, no sane person would ask for such to be ploughed at present, because there are many plots of an opposite character that should by compulsion be ploughed and made to grow their share of corn. There are persons who excuse themselves by saying, "Oh, that field is too wet to grow Corn"—then, I say, make it drier; all too often the natural watercourses are not kept free; if they were, an improvement would quickly be apparent.

I cannot overlook the fact that there are many thousands of acres already under arable culture that do not produce crops sufficient to warrant the treatment they receive, and they need manure. Where *bona fide* want of capital prevents the purchase of manures the Government is prepared to assist by granting loans.

It is surprising what increases in the Oat crops can be secured by the aid of sulphate of ammonia sown at the rate of 1 cwt. per acre at the right moment; not only does this stimulant increase the yield by several bushels per acre, but there is, naturally, a corresponding increase in the bulk of straw, which is a boon to the cattle. The increase in crop does not stop at the Corn and straw, but we should consider the extra manure that is produced, which means in the near future still heavier crops of cereals, roots, or Hay.

There does not appear to be a shortage of motor ploughs; if there is, the various agricultural committees are prepared to send out horses and men to plough either grass or arable land. Therefore there need be no hesitancy in ploughing on that score. It is, perhaps, now too late to sow Wheat on newly ploughed grass-land with a prospect of success, although there are some few exceptions in situation, and with the newer varieties of Wheat that are more adaptable to late sowing, success may still be assured.

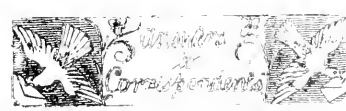
Oats are quite the most certain of cereals to sow on newly ploughed grass-land, because this cereal luxuriates in new turf more than any other. The months of February and March are quite early enough to plough grass-land for next season's Oat crop, but it is advisable to procure at once the necessary manures which so facilitate the growth of the plant, because it may be difficult to procure them later.

By way of illustration and as a guide to the inexperienced who contemplate ploughing a plot or more of what I term a poor pasture—one that only produces half a ton of Hay per year, with a little aftermath feed for cows. Such a pasture possibly has not had manure for twenty years, but the grass has been cut, made into Hay, and carted off the field all the same, until the soil has become so poor that its principal crop is Ox-eye Daisies. Such a plot will produce as many as 56 bushels of Oats per acre. This, at the present Government price of 45s. 5d. per quarter, would amount to £15 16s. 9d. The manures required would be, say, 4 cwt. of agricultural salt, 3 cwt. superphosphate, and 1 cwt. sulphate of ammonia, in all costing, say, £3 per acre. Add to this ploughing, harrowing, rolling, sowing, and harvesting and thrashing, with rent, in all, a round sum of £6, with the straw thrown in. Multiply this acre by twenty or forty and see what is the result—surely a reasonable profit and much pleasure in the production of valuable food for the country.

Potatos succeed admirably on newly ploughed grass-land provided the method of cultivation is correct. Plough at once 4 inches deep, using the skim coulter well to bury the turf. In every furrow use a subsoil plough as deep as possible to provide a better root-run for the

MR. EDWIN MOCKNEY.

Potatos. In February cross-plough deep enough to bring the turf upwards to enable its being disintegrated and made friable by repeated harrowings before planting time comes round in March or April, according to the situation. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham.*



FLOWER OF SPRING CABBAGES OPENING. If you do not state when the Cabbages were planted; if they were set out too early they would be almost certain to make succulent leaves, which, if arrested by sharp frost, would be liable to open and present a bleached appearance.

FOOD CROPS IN FRAMES AND GLASSHOUSES. *H. F. H.* Potatos offer one of the best food crops for cultivation under glass. Early varieties that mature quickly, such as May Queen, Duke of York, Sharpe's Express, and Puritan, all of which are strong growers and heavy croppers, should be chosen. The sets should be placed in shallow boxes at once and sprouted in gentle warmth. Plant the tubers carefully, when the shoots are 1 inch long, in rich soil, allowing a distance of 2 feet between the rows and half that distance between the plants in the rows. Carrots should be sown in frames at once in rich soil, and the surface of the bed should be within 15 inches of the roof-glass. Early Gem is the best sort for sowing now. Cauliflowers may be grown in pots, and the seeds should be sown at once. Early Forcing and Magnum Bonum are suitable varieties. Tomatos may be planted largely in heated houses. The seed should be sown forthwith in heat and the seedlings potted as soon as they are large enough for transference. Successional sowings of this vegetable should also be made, choosing the variety Ailsa Craig.

NAMES OF FRUITS: *H. A.* 1, Barnack Beauty; 2, Gravenstein.—*G. F. M.* Apple Thomas Rivers; Pear decayed.

NAMES OF PLANTS.—*Correspondents not answered in this issue are requested to be so good as to consult the following number.*

Charles O. L. Pearce. Aeschynanthus speciosus. Native of Java. Introduced in 1845.

POTATOS WITH DISCOLOURED FLESH: *W. T.* The internal markings are caused by the disease known variously as "internal disease" or "sprain." It does not cause a rot, and the tubers can safely be used as "seed."

TENNIS COURT WITH HARD SURFACE: *J. L. B.* If the soil on which your tennis court is to be made is chavey or close, draining will be necessary before making the surface. For this purpose, use 2½ inch agricultural tiles at 9 or 10 feet centres to the main drains, and 4-inch field pipes at the sides. At the bottom, place a layer of stone shivers, rough engine ashes, or gravel, whichever is most easily available, to a depth of 4 inches, and carefully level and roll them. Place a layer of finer ashes 2 inches deep over the rough material, and level and roll again. Next place a layer of fine blaes to a depth of 1 inch, or broken brick may be employed if blaes is not procurable. Again roll firmly, and then place a layer of ½-inch blaes or brick to a depth of half an inch, level, water, and roll again. Finish off with a coat of fine screened blaes or brick ¼ inch size, and level, water, and roll once more. A good finishing material is Hart's fine brick and tile dust composition. The pre-war cost of a tennis court on the above lines would be from £70 to £100. To make a tennis court of tar-macadam, proceed as follows. After the ground has been levelled and consolidated, fix a creosoted wooden border 3 inches by 1 inch round the required area. At the bottom place a layer of broken stones or brick, size about 1½ inch or 2 inches, to a depth of 4 inches, mixed with shivers or ashes; roll thoroughly with a 10 or 15 cwt. roller. Then place 1½ inches of tar macadam in two layers, the first composed of stone in 1½ inch and 2 inch sizes, thoroughly coated with standardised bituminous tar, the second composed of crushed limestones which will pass through a ¾ inch screen, but not through a ½ inch screen, heated and mixed with bituminous tar. Roll each layer separately. From centre to sides it is necessary to have a slope of about 1-16th to 1-8th of an inch to allow of the water draining from the surface to the sides of the court. After the tar macadam has had about a week to harden, it is advisable to paint it with a light coat of bituminous tar and dust the surface with powdered limestone, which will fill up the interstices and leave a surface practically impervious to water. The pre-war cost would vary from 2s. 6d. to 3s. per square yard.

TENANT'S GREENHOUSE: *A. B.* If, as appears to be the case, the structure was merely resting on the ground by its own weight, you were quite entitled to remove it; you should ignore the demand for its return, as well as the false accusation which you suggest this demand implies.

THE
Gardeners' Chronicle
No. 1620.—SATURDAY, JANUARY 12, 1918.

CONTENTS.

ILLUSTRATIONS.

THE MARKET FRUIT GARDEN.

THE old year ended and the new one began with a continuance of the wintry weather which started on December 2. Comparatively few nights in December were free from frost, while on many days the temperature in the shade did not rise above freezing point, at least on the ground level. As a rule, however, in my southern district the frost was seldom severe, the maximum being 11 on the screen on the night of the 19th, while only once besides the degrees of frost exceeded seven. In the latter half of the month there was more snow than we commonly have in December, and the fall of the 16th remained on the ground longer than any previous fall during my seventeen years' residence in my present home. The renewal of snow on the last night of the past year, only two nights after the land had been cleared, was unwelcome. Throughout nearly the whole of December the wind was in a cold quarter, at first mainly north-west or north, and later north-east or north.

THE RAINFALL OF 1917.

The following table shows the rainfall and number of days on which it was measurable for each month in the year at my station:

Month.	Fall in Inches.	Number of Rain Days.
January	1.18	12
February	0.82	6
March	1.45	19
April	1.45	14
May	1.50	10
June	3.51	7
July	2.57	11
August	5.66	20
September	1.50	9
October	4.29	22
November	1.50	8
December	2.24	13
Year	27.67	151

The figures for the year compare with 33.90 inches and 171 rain days for 1916, and with 29.86 inches and 150 rain days as the average annual totals for the sixteen years of my residence here, up to the end of 1916. It will be seen that the total fall for 1917 was more than 2 inches below the sixteen years' average, in spite of the excess in June and the great excesses in August and October. The heaviest annual rainfall in the seventeen years now completed was 37.16 inches for 1903, 36.50 inches for 1915 being next. The lightest was 19.32 inches for 1901, followed by 22.70 inches for 1902, and 24.10 inches for 1904. In no other year was the fall so little as 26 inches. Since 1908 the total has never been so little as 27 inches. If I had any choice as a fruit grower in my present place, I should choose an annual rainfall of 20 inches to 24 inches. The great or considerable excess over the latter quantity in the last nine years I hold accountable for the increase of fungous diseases, particularly Brown Rot.

WORK HINDERED IN DECEMBER.

Efforts towards making good as far as possible the impairment in the condition of orchards due to the serious hindrances to hoeing throughout the greater portions of the summer and autumn were largely frustrated by the wintry character of December, when digging was not half done. The women, upon whom mainly reliance for digging has to be placed this season, came to work on fine mornings, when the land was not too wet, covered with snow, or hard with frost, but were often sent home by rain or snow, and the few men available have had to spend much of their time in hedging, instead of digging. However, if we should be fortunate enough to get a good spell of favourable weather before the end of February, there will be time to finish the work. For pruning the weather has been too cold to be

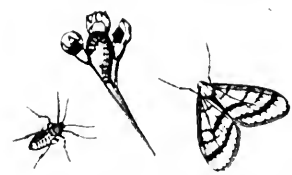

FIG. 7.—WINTER MOTH: CHEIMATOBIA BRUMATA. WINGLESS FEMALE AND WINGED MALE.

pleasant, but snow on the ground has not stopped it, and the pruners have persevered with their work on most days, except in the first two hours of the coldest mornings, when more stirring operations were substituted.

WINTER MOTH AND FROST.

Early in December, on the day after 8° of frost had been registered 4 feet from the ground level, some female Winter Moths were found on an Apple tree in a perfectly lively condition. One male was found on the same day. This appears to indicate that the pests can withstand a considerable severity of frost. Possibly they would not survive a prolonged frost, but the females might live long enough to deposit their eggs.

FRUIT CROPS AND PRICES IN 1917.

Strawberries, Raspberries, and Cherries I do not grow for market, but they yielded well as grown for home use, reckoning blackbirds and starlings as home users in relation to Cherries, nearly all of which they consume. Black Currants with me were not so abundant as in 1916, the bushes in my largest orchards having passed their prime. Prices were highly satisfactory, beating the record, so far as my experience goes, but not yet sufficing to make the total return equal to that of 1916. There was a good crop of Plums, taking all varieties together, but prices were low, mainly in consequence of the shortage of sugar—much lower than in 1916, and still further below those of the peace year, 1913. Moreover, the averages for late Plums were greatly reduced by the very large proportion of "drops," blown off by gales, which had to be sold at 1s. per half-sieve, or less. Even for gathered fruit prices were much lower than in 1913. The greatness of the yield of Rivers's Early Prolific, which started well, caused a slump after a week or so, and this affected the sale of Czars, while Victorias, Monarchs, and Pond's Seedlings made only moderate prices. My ranges, with rail and market expenses to come off, were 2s. to 6s. 9d. per half-sieve for Early Rivers, as compared with 7s. 6d. to 8s. in 1915; 5s. to 5s. 6d. for Czars, against 5s. 6d. to 8s.; 2s. 3d. to 5s. for Victorias, against 4s. 6d. to 6s. 6d.; 3s. to 4s. 6d. for Monarchs, against 5s.; and 3s. to 4s. for Pond's Seedlings, against 5s. to 6s. 6d. As to the Apple crop, it it had not been for the almost complete destruction of the blossoms on hundreds of trees, and the partial destruction on most others by the phenomenal attack of caterpillars, we should almost certainly have had a record crop. As it was, although immature trees of some varieties yielded badly, those that did crop fairly or abundantly gave quantities beyond expectations, because of the almost entire absence of "scrumps," and the full or fair size of the fruit generally. As with Plums, however, the gales brought down huge quantities of fruit, and these "drops" had mostly to be sold at low prices, though not much lower than gathered fruits of the same varieties have made in some past seasons. It was not until the glut caused by the hurried marketing of "drops" was finished that prices rose above an average peace-time level, but then they became higher than they had ever been in my experience, except, perhaps, in an occasional year of extreme scarcity. The lack of the competition of American and Canadian Apples had much effect upon prices after October.

Pears, which do not flourish in my district, and are grown on only a very small scale, cropped fairly on the whole, and sold well.

APPLES KEEPING WELL.

There are reports to the effect that Apples are not keeping well this season. Where this is the case, I think the reason must be either that they were gathered too soon, or that "drops" were stored with gathered fruit. There is no advantage in storing even the best of keepers without selecting them for perfect soundness, and selling all that are bruised or flawed in the slightest degree before the end of November. It is my usual practice to select and store the main portions of the late keeping varieties, partly until December, and partly till February or March. Lane's Prince Albert and Blenheim Pippin will usually keep well until Christmas, or possibly later, while Bramley's, Newton Wonder, Dumelow's Seedling, and Chelmsford Wonder should remain sound generally up to March. I have never known these varieties to keep better than they have kept this season. In consequence of the unusual prevalence of sooty blotch, however, I have kept a smaller quantity of Apples than usual. Probably the fungus does not affect keeping quality, but there was the fear that it would develop and possibly spread in store, so that it seemed advisable to sell the disfigured Apples when the best were selected for long keeping. If it had not been that the latest varieties were keeping remarkably well, the temptation to sell out at the high prices of December would have been irresistible. If there be any truth in the rumour that some American or Canadian Apples are to be allowed to come as parts of cargoes, the speculation of keeping some of home growth may prove an unfortunate one. In any case, however, a grower who is holding over a moderate quantity should not be condemned as a "profiteer," because it is certainly desirable that a portion of the Apple crop should be kept back to meet the demands of consumers in February and March.

QUALITY IN CULINARY APPLES.

Although among my culinary varieties of Apples there is not one which does not cook well, there are differences in sweetness, flavour, and proportions of waste in relation to thickness

or thinness of skin and size of core. Some tests made this season with early, mid season, and late varieties have thrown light upon these points. The method of testing adopted was that of trying the Apples baked whole and eaten when hot or warm. Early Julyan, which is sold for dessert as well as for cooking, mashed well, and needed only a moderate quantity of sugar, an important merit at the present time. The skin is thin, and the proportion of core is not large. It was not surprising to find Charles Ross, a regular dessert variety, sweeter, and it must further be declared the richest in flavour of any of the varieties tested, although Newton Wonder proved a good second in the two meritorious points named. The former has a somewhat thick skin, and a larger core than some of the other varieties, while the latter shows less waste. By the way, Newton Wonder is one of the pleasantest Apples to eat in its raw state at this period of the season. It is sweet, juicy, and firm, and although it has not much flavour other than sweetness, this may be said of nearly all the dessert Apples that keep well over Christmas, as they lose the spicy flavour which characterises them when they are gathered. D'Arcy Spice Pippin is an exception, and Allington Pippin is at its best at the present time—the best not being very good. Cox's Orange Pippin also keeps its flavour well, but is now past its prime. To return to the cooking test, Chelmsford Wonder was found, as in previous years, to be one of the best of cookers, while its skin is very thin indeed, and the waste in core is small. It requires a little more sugar than Bramley needs, and the latter is to be commended for fairly rich flavour, but its waste in thickness of skin and core is considerable. Dumelow's Seedling, more commonly known as Wellington, is justly famous as one of the best cookers. Its substance is soft and juicy, and its flavour excellent, while it is not at all wasteful in skin or core. But it is wasteful in respect of sugar, as its acidity is much greater than that of any of the varieties named above. Close to it in this last respect, but not nearly up to its merits, is Bismarck, which I should place lowest in the list of Apples tried. Lane's Prince Albert is a very good cooker, but not particularly striking in any of the points mentioned. To go back to a mid season variety, Royal Jubilee must be praised as one of the most economical cookers, as it needs hardly any sugar, and its skin is very thin. Its flavour is fairly rich, though less so than that of Charles Ross or Newton Wonder. Queen is more acid and more wasteful in skin and core. Warner's King is of richer flavour than Queen, but has one of the thickest of skins, and in texture is coarser than any of the varieties named above, with the possible exception of Bismarck. *Southern Grower.*

FIG. 8.—PRUMNOPITYS ELEGANS AT KEW (IN FOREGROUND). 12 TO 15 FEET HIGH.

NOTES ON CONIFERS.

XVIII.—PRUMNOPITYS ELEGANS.*

THIS South American Conifer, sometimes known as the Plum-fruited Yew, is of comparatively recent introduction, having been first sent to England in 1860 by the Veitchian collector, Richard Pearce. In the Andes of Southern Chile it is an alpine tree having a vertical range of 4,000 feet to 6,000 feet. In cultivation it is generally bushy in habit, any plant over 10 or 12 feet high being considered an exceptionally good specimen. In England it appears to prefer the milder climate of the western counties, where it attains a larger size than anywhere else in the country. The best specimen I know of is in the famous collection at Menabilly, in Cornwall. This tree was 35 feet high when I measured it in 1908, and branched into many stems at 1 foot from the ground. Unfortunately I have no record of the date when this fine specimen was planted. There are also notable examples of the Plum-fruited Yew at Tortworth Court, Gloucester, where I saw it fruiting last year. Mr. Banting, gardener to Lord Ducie, informs me that the largest specimen at Tortworth is now 20 feet high, and was planted in 1879. Eastnor Castle, Ledbury†; Kilmacurragh, Co. Wicklow; Fota Island and Lakelands, Co. Cork; and Poltalloch, Argyllshire, are other places where this Conifer has done exceptionally well.

At Rostrevor, Ireland, there is a tree about 25 feet high. I shall be glad to hear of any exceptionally good specimens.

At Yattendon Court, Berkshire, where there is an interesting collection of Conifers planted by the late Mr. Alfred Waterhouse in 1878, the Prumnopitys has attained a good size, and several trees fruited freely in 1913, as will be seen from the illustration in fig. 10. The fruit, which is not common in cultivation except in favourable seasons, is eaten by the Chilians. The Kew trees are the best I know near London, and probably date from the early seventies, but there is no official record of their having borne fruit. Webster‡ says: "It thrives satisfactorily when planted in smoky and dusty localities, and may sometimes be seen potted up and offered for sale in Covent Garden market; it makes a neat and effective pot plant, and one which, unlike many other Conifers, does not change colour with the advent of winter." Hansen§ says that Prumnopitys is rarely met with on the Continent except in Western France, as in gardens at Cherbourg. He adds that the wood is said to be very fine-veined, and consequently much valued by ebonists. Authorities differ as to whether the Plum fruited Yew is to be kept as a distinct genus, or placed among the Podocarps. The genus Prumnopitys was founded by Professor Philippi, of Santiago, in 1859 (*loc cit.*), on the plant now under discussion, Philippi having previously described it as Podocarpus andina, a name retained by Pilger, the latest monographer of the Taxaceae, and often wrongly applied to another species, P. chilina. In the true Podocarps, however, the peduncle and ovule-bearing scale become fleshy when mature, while in Prumnopitys this receptacle does not become fleshy, "receptaculam carnosum nullum," the fruits being pseudo-terminal or sessile on a common rhachis. In 1847 Endlicher proposed the name Stachycarpus for a section of the genus Podocarpus distinguished by this character and included in it P. spicata, P. andina, P. ferruginea, P. falcata, and P. taxifolia, and this section, containing species having fruits on a loose spike the axis of which does not become fleshy, was afterwards established as a genus by Van Tieghem, who gives an elaborate account of the structure and affinities of our plant, correctly citing it as Stachycarpus andinus. One hesitates however, to disturb a name in common use, and the substitution of Stachycarpus, a name practically unknown to the majority of botanists and horticulturists, would certainly lead to confusion. I therefore hesitate to adopt it. *A. Bruce Jackson.*

4d. WEEKLY, Postage ½d.

THE GARDENERS' CHRONICLE

19/6 YEARLY, Post Free.

Published every Friday at 41, Wellington Street, Covent Garden, London, W.C. 2. (Telegrams: "GARDCHRON, RAND, LONDON." Telephone: GERRARD 1543).

The dates of Meetings herein given, supplied by the Secretaries of the respective Societies, are as complete as circumstances will allow, but some appointments are not made at the time of publication, and others are liable to alteration.

☞ During the operation of the Daylight Saving Bill the times given for Astronomical and other notes must be altered accordingly.

JANUARY.

DEGENERATION OF POTATOS.

THE question of degeneration of Potatos is well worthy of consideration in these days of the necessity for an increased production of food. I am firmly of the opinion that in the great majority of cases Potatos destined for seed purposes do not receive good treatment, and at the present time every endeavour should be made to encourage those seedsmen and growers who make the production and selection of seed sets a speciality. The whole history of the cultivated Potato reveals the necessity of wise and judicious planting for the production of seed tubers. The importance of keeping stock in a high state of excellence is realised by every producer of foodstuffs, and the recent sales of pedigree Shorthorn cattle in the North of Scotland, record prices being the rule, show that the stockbreeder, at least, is determined to maintain his herd in an efficient condition. If it pays the stockbreeder to give huge prices for stock, it will also pay the Potato grower to buy seed sets that have been carefully selected. The average Potato crop per annum is something above six tons per acre. I saw crops raised last autumn which yielded a return of 20 tons per acre. This is an instance of a commercial and not an experimental planting of Potatos. In trials last season I saw returns well over 40 tons per acre, and this simply instances what the Potato is capable of doing if soil conditions and the seed are right.

There can be no question, I think, that degeneration in certain Potatos is an accepted fact. How, considering average conditions, could it be otherwise? A decade ago this matter was the subject of an article in the *Journal of the Board of Agriculture*.* In that article it was pointed out that during the past few years many inquiries had been addressed to the Royal Botanic Gardens, Kew, as to the reason why Potato tubers failed to form sprouts at the proper season, even when placed under proper conditions for doing so. This condition of things, it was stated, was not confined to this country. In Germany† serious losses were sustained owing to the sterility of Potato sets. The German experience was that very few of the eyes produced sprouts, and the sets at the time of lifting were not shrivelled and dried as is the case under normal conditions, but were solid and firm and in many cases had actually increased in size. The results of investigations made by Dr. Schlich and Dr. Steikermann proved the absence of any specific disease, and failure was attributed to the practice of growing the same kind of Potato from sets produced on the spot for a long time.

A French investigator, Dr. Delacroix,‡ described the occurrence, on a large scale, of a similar sterility of Potato tubers. In this case there was also an absence of any specific disease, and the trouble was considered to be due to decadence and loss of vitality brought about by the employment of the asexual method of reproduction invariably followed.

We have thus three very definite cases of decadence recorded over ten years ago, and the non-sprouting of seed sets was undoubtedly a very common occurrence last spring. The writer of the article in the *Journal of the Board of Agriculture* to which I have already made reference states that the sterility, or failure to form sprouts, was investigated by experiments conducted at Kew, and extending over three years. The non sprouting trouble was accompanied by a combination of two distinct specific conditions. These were stated to be: (1) more or less arrest of the development of the vascular system of the tuber; (2) comparative absence of the ferment or enzyme called diastase from the tuber.

The results of investigation, so far as the article referred to is concerned, point out that degeneration in Potatos has been caused by the methods of selection and the lines followed in producing certain improvements, which have in some instances favoured other unsuspected modifications, which have resulted in sterility of the tubers. The improvements cited are: increase of crop; improved flavour; smooth and even surface; immunity from disease.

The summation of the matter simply amounts to this: The demand by the public for ware is for tubers that possess a shallow eye, so as to avoid waste in paring. I admit, of course, that no Potato should be pared, but the majority of consumers still require education upon this point of domestic economy. Whilst a tuber with a shallow eye may be an improvement from the culinary standpoint, it is the result of certain methods of inter-breeding and selection which have been accompanied by a serious degeneration—in the case of many varieties—of the fibro-vascular system. In short, shallow-eyed tubers are defective in a means whereby the starch stored in them can be utilised by being converted into a liquid condition in order to feed the young shoot emanating from the shallow eye. It is declared that in many high grade Potato diastase is produced in such small quantities that it can only convert a very meagre proportion of the starch that is present into sugar. Thus the shoot must emerge from the eye usually at the apical end of the tuber in a state of semi-starvation.

Now, the above facts may explain another matter. During the last ten years the country has had to combat Wart disease due to Synchytrium endobioticum. I have observed that many of the most consistently immune varieties to that disease are sorts having deep eyes. That was a type of Potato that was practically driven out of commerce, but as necessity knows no law growers who have to deal with infected soil conditions have been compelled to accept them. Are these deep-eyed immune varieties they possess undoubted vigour and they are heavy croppers able to develop such a sufficiency of diastase that they feed the shoot so thoroughly and satisfactorily that it gives it great power to resist the attacks of the fungus which causes wart disease? On the other hand, are shallow eyed varieties unable to develop sufficient diastase to enable them to feed the shoot so that it has the power or stamina to resist attack? These are points which scientists might consider. In an attack of wart disease it is known that infection take place through the eyes of the tuber, and investigators have stated that the starch grains are the last to be attacked, and remain white and uninjured in the affected cell.§ Has the spread of wart disease been promoted by degenerate varieties of Potatos?

Our hitherto loose methods in the importation of seed sets have also resulted, to a certain extent, in the introduction of the disease known as Macrosporium solani. Dr. Hornet has instanced at least three separate occasions upon which "leaf curl" disease has been introduced into Scotland from the Continent with the Potato known as "President." This disease is, I am afraid, spreading very rapidly in Britain, and the authorities may require to give it serious attention. It is, apparently, a disease of a contagious character, and would seem to require control, otherwise another certain source of degeneration is likely to arise. Had wart disease only been rigidly dealt with on its first appearance, how much destruction might have been saved! Let us try and avoid more trouble in respect of notifiable diseases amongst Potatos, but this can only be done by encouraging the selection of sound seed by careful growers.

It has yet to be proved, I think, that vegetative methods of propagation are responsible for degeneration. Take, for example, the case of the old show Dahlia "James Cocker." Mr. Robert Fife, an undoubted expert upon the Dahlia, assures me he has propagated that variety from cuttings for over forty years, and he sees no sign of degeneration. He maintains that it is still as good as it was when he handled it first. I have yet to learn, too, that Potatos raised from cuttings will degenerate provided that the cuttings are well cultivated. I have seen some heavy crops raised from cuttings, but further experience with the tubers so raised is necessary before any statement can be made on this method of propagation.

It is clear that there has been degeneration in many varieties of Potatos during the last twenty years, but I would attribute this almost solely to inter-breeding coupled with bad methods of seed selection, and careless cultivation. *George M. Taylor.*

A DAY'S TRAMP IN THE HIMALAYAN FOOTHILLS IN OCTOBER.

STARTING out from Motiana (7,984 feet above sea level), we skirted some precipitous rocks with many waterfalls. Here was the wild Maidenhair in profusion, and a red succulent plant of the Sedum class, making a bright show of colour, but not now in flower.

We also noted a delicate pale blue Hawkweed, a branching Harebell, a wild white Scabious, and a belated Begonia still in bloom. Along the watercourses white Spiræas were flowering, and later in the day we saw several plants of wild Doronicum, and a most beautiful Delphinium of blue shade. The coolies, who seem to be very fond of flowers, presented my wife on the way with bunches of wild Violets and Cinerarias. The ground in places was carpeted with Potentilla nepalensis, making a rich glow of colour. We passed an orchard at the hamlet of Kodiali, and shortly afterwards we had tiffin, when the woods got thicker, and selected a site near some magnificent Deodars, while Spruce, Firs, and Holly give the locality quite an English aspect. After an hour's steady climb we suddenly debouched upon Narkanda (9,132 feet), showing a wonderful panorama of snow mountains beyond the wooded Pine slopes.

The next morning we took a walk along the Baghi road, covering just four miles in the hour. Here the lateral growth of the Pine trees is but feeble, but in height they more than atone for their lack of breadth. We came to huge slabs of rock, which run straight up in jagged blocks, giving the effect of flying buttresses of some giant cathedral, and well named "The Cathedral Rocks." Their bare sides are softened by grey blue clumps of a beautiful rock Campanula, the feature of which is the length of its stigma; the natives call them "Sinseri," and these, combined with Maidenhair and wild Cinerarias growing in the crevices of the rock, could not have been bettered by any rock garden made by human skill. On the return journey a large snake crossed our path, and we had much difficulty restraining the natives from stoning it, but the snake seemed eager to hide itself in the jungle opposite, and quickly achieved its purpose.

We passed some terrestrial Orchids, now, alas! dying down; no seed remained, but what was left of stem and leaves resembled a Bee Orchid. The sun had now gone in, and it was so cold that when we reached the Dâk Bungalow at Narkanda we had to warm ourselves by a fire before tiffin. The afternoon we spent admiring the panoramic effects of the snow mountains, and we better to do this we climbed up 300 feet, and from here we could see Simla, and Jakko Mountain, nearly fifty miles to the south, and obtained a complete view of the range of snow mountains to the north. *Charles Orr White (Captain).*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

PREPARATIONS FOR FORCING.—A sufficient quantity of leaves and stable litter should be prepared as fermenting material for the hotbeds. Fallen tree leaves are to be preferred to manure, as they furnish a more gentle and lasting warmth. If an isolated bed is made, it should be about 18 inches wider than the frame to be placed on it. Mix the materials well together, turning them at short intervals, to allow the rank gases of fermentation to escape

CARROTS.—Young tender Carrots may be grown in brick pits for very early supplies, using only sufficient fire heat to keep out frost. The sweetest and most delicious roots are those grown in frames during April and May. Should the weather continue favourable, prepare a bed and sow the seed with as little delay as possible. Two lights will afford roots over a long time, and a second sowing made a month or six weeks later will continue the supply. Early Gem, Champion Scarlet Horn and Improved Early Horn are suitable varieties for forcing.

FRENCH BEANS.—In winter French Beans give only very light crops, and they need much room and fire heat; batches raised during the next two months are much more productive. Kidney Beans require plenty of warmth, light and room, and unless these conditions can be provided it is unwise to sow seeds before March, when climbing French Beans, such as Tender and True, are much more profitable. The climbing varieties may be planted out and the shoots trained close to the roof-glass on strings or sticks. Magpie, Ne Plus Ultra, and Canadian Wonder may be sown in 8-inch pots from this date forward.

PEAS.—Peas are not amenable to hard forcing, nor are they very profitable under glass, but an early crop may be had, and the best results are obtained by growing dwarf varieties in pots. The plants need plenty of light and air. Seed of such varieties as Little Marvel, Laxtonian, Pioneer, and Excelsior may be sown at once in small pots to have plants in readiness for forcing when pits are available.

GENERAL REMARKS.—Roots of Rhubarb and Seakale should be prepared for forcing according to demand, selecting the strongest crowns for the purpose. A Mushroom house, or any dark, warm structure will be found suitable for forcing these plants. Set up seed tubers of early varieties of Potatos in trays or boxes; place the very earliest varieties, such as Sharpe's Victor, May Queen, and Midlothian Early, in a warm pit for growing in pots and frames later.

THE ORCHID HOUSES

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

SEED-SOWING.—The raising of seedling Orchids is now very general, and in many establishments hybrids are the principal feature of the collection. Many of the seed vessels are ripening, and with the turn of the year, bringing lengthening days, the conditions become favourable to the successful germination of the seed. Orchids may be dealt with in two groups, epiphytic and terrestrial. Seed of the terrestrial group, which, so far as potting purposes are concerned, may include Odontoglossums and Cochlodas, is best sown around the base of a plant of the same genus. Some raisers are successful in sowing on pots of about 60 size containing medium sized seedlings, whilst others have equally good results by using larger pots containing older specimens. If large specimens are used as host plants, select varieties of no particular merit; for example, some of the O. Edwardii crosses; such plants may be utilised during successive or alternate seasons. The plants should be repotted at least one month previous to seed sowing, and it is always advisable to sow in several pots, in order to ensure a crop of seedlings. Before sowing, water the compost freely, and scatter the seed evenly over the surface. For several weeks afterwards use extra care in watering, or much of the seed may be washed away. In dealing with Cypripediums, select plants that have been recently repotted or those with compost in a sweet, healthy condition. With epiphytic Orchids, and particularly those of the Cattleya group, a different procedure must be adopted. It is best to have suitable cases in which to hasten the germination of the seeds. If cases are not available, a propagating frame may be substituted. The temperature must be kept equable and the surroundings moist. In a close frame there is less evaporation of moisture than in the house itself, therefore there will be less need for frequent waterings. The following is the method of sowing:—Place a piece of new canvas, cheese cloth, or some such porous material about 4 or 5 inches square, on the palm of the hand, and cover it with finely-chopped Sphagnum moss. Wrap the edges of the cloth about the moss, forming it into a ball. The ball should be pressed firmly into a well-drained pot or deep Orchid pan without side holes, of a size just large enough to hold it. Let the surface be ½ inch below the rim. Fill the sides with chopped Sphagnum-moss, from which the larger heads have been removed. The seeds sometimes fail to germinate on the canvas, when a good crop is secured on the Sphagnum moss, while the reverse often occurs. The material in the pots should be watered thoroughly, and when the superfluous moisture has drained away, the seeds may be sown on the canvas. Transfer the pots to the cases. The soil should never be allowed to become dry, and the pan should be shaded from strong sunlight.

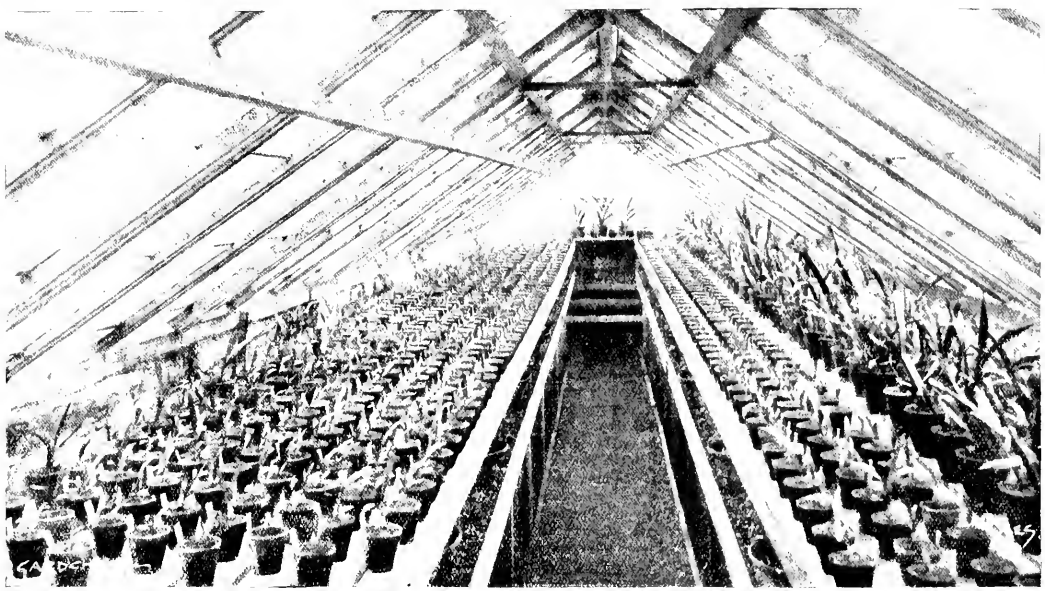

FIG. 9.—HOUSE OF SEEDLING ORCHIDS.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

FIGS IN BORDERS.—Considerable economy in fuel may be effected by not starting early houses containing trained trees growing in borders. In the meantime the work of pruning should be completed at the earliest opportunity. Remove old, exhausted, and weak growths wherever there are sufficient short-jointed, medium-sized shoots to replace them. Some of the new shoots at the base of old, established trees trained on trellises near the roof-glass should be trained in to replace old, fruitless branches. After the work of pruning is completed tie the branches in bundles and sling them temporarily to the trellises with stout cord. Scrub the woodwork and wash the glass with soap and water, and limewash the walls. The trees may then be cleansed thoroughly of insect pests, such as scale and red spider, by means of an insecticide. When tying the branches permanently allow sufficient space for light and air to enter the tree. Give the borders attention, removing old top-dressings and mulchings, and replace with a compost consisting of fibrous loam, mortar rubble, wood ash, and a small quantity of

manure from a spent Mushroom-bed. A mulch of half-decayed manure may be applied with advantage when the fruits are swelling. Should the borders be dry give sufficient water to wet the roots thoroughly before the trees are started into growth: until that time the houses should be left open and kept as cool as possible. When forcing is started maintain a moist atmosphere. The night temperature should be 50° to commence with, gradually increasing the amount of warmth to 55° when the trees break into growth. The opportunity may be taken when pruning to select a few well-ripened shoots, some 3 or 4 inches long, as cuttings. They will root readily in a moist atmosphere and, with careful pinching, form fruiting trees in twelve months.

FIGS IN POTS.—Early Fig trees in pots in active growth require plenty of water at the roots. Use tepid water both for watering and syringing, which should be done twice daily. Maintain a moist atmosphere with a free circulation of air. Late trees in pots for successional fruiting should also receive attention. Follow the treatment recommended for Figs in borders.

MELONS.—With inefficient labour it is not advisable to sow Melon seed too early, for unless a suitable temperature is maintained the plants will be ruined in their early stages of growth. Where there is no difficulty in this respect, select seeds of an early variety, sow them singly in small pots, and plunge the seed-pan in a bottom heat of 75°. When the seedlings are through the surface place the seed pans near the roof glass, to ensure sturdy growth. The plants may be repotted once before they are placed in large receptacles.

PROPAGATING VINES.—Should young vines be required for planting this year they may be raised from eyes inserted at the present time in uno moiel Melon or Cucumber pits. Place the eyes singly in 2½ inch pots filled with fibrous loam. The temperature should be 65°, and the atmosphere not too moist.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

FRUIT TREES ON WALLS.—Take advantage of every favourable opportunity to complete the work of pruning and training. With good management, the work may be done without much discomfort to the staff. If wall nails are used, the French nail of wrought iron is much more durable than the older kind of cast iron. The point is more blunt, but with care this defect will not occasion any trouble. Medicated shreds have now almost superseded the older sort made of ordinary cloth. The shreds may be had in reels of various widths, to be cut into suitable lengths. I have been forced to use the tips of the yellow Willow for tying, and they are quite suitable when in expert hands. The use of wires on fruit walls does away to a great extent with the need for nailing. The wires are strained horizontally along the wall, but perpendicular strands of tarred string must be supplemented for Peach and Nectarine trees or any kind of tree trained in fan shape. I am not in favour of galvanised wire, and have discarded it for wrought or annealed wire. I found that the young growths of Peaches and Nectarines were killed when they came into contact with the galvanised wire. To remedy this I had recourse to painting, and found that to be efficacious. This also needs to be done occasionally in the case of the wrought wire. In wiring walls, a mistake is frequently made of arranging the wire at, say, one inch away from the wall, whereas it should be as close to the wall as possible, to prevent cold currents of air passing behind the trees.

AUTUMN-FRUITING RASPBERRIES.—I strongly recommend the cultivation of autumn fruiting Raspberries. The fruits are most useful, both for dessert and cooking purposes. They are in season with us from the middle of August to the middle of November. In France I have seen the canes bearing very heavy crops. In one instance I noted that the plants were temporarily covered with old lights to obtain fruits as late in the season as possible. I would advise that a small plantation, at least, be formed. Ground for planting this small fruit should be prepared at once by deep trenching. Dig in a fair amount of farmyard manure as the work proceeds. The canes should be cut down to the base and planted in rows at 4 feet apart, allowing a space of 2 feet between each set of stools. Planting should be finished early in February. It is immaterial whether the plantation is made in a light, open situation or one shaded by other fruit trees, provided the shading is not very dense. Where the ground contains roots of other fruit trees it is not possible to trench in the same thorough manner as in the open, but it should be kept well cultivated. During the past season our best crops were obtained from canes that were rather heavily shadowed by early standard Cherries. In this instance the variety was the Hailshamberry, which with us is one of the best of the Brambles. The old Belle de Fontenay is not to be despised; it is one of the dwarfest and wants but little support. November Abundance, a more recently introduced variety, has also proved to be excellent for its late fruits.

PLANTS UNDER GLASS.

By E. J. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CHRYSANTHEMUMS.—The bulk of the cuttings should be inserted without further delay, so that the old stools may be disposed of. Any varieties which have failed to produce sufficient cuttings should be placed in a warm house and syringed twice daily. Recently-rooted cuttings must not be coddled, or they will make spindly growth. Place them on a shelf near the roof glass in a house from which frost can be excluded. These young plants must not be exposed to cold draughts.

WINTER FLOWERING PELARGONIUMS.—After Pelargoniums have finished flowering they should be placed near the roof glass in a light, airy house, where the growth will become somewhat hardened and suitable for cuttings. When ready, the shoots may be taken off and inserted around the sides of 5 inch or 5 inch pots in a compost consisting of loam, leaf mould, and sharp sand. Pass the soil through a ¼ inch meshed sieve. Place a little fine sand at the base of each cutting, as it is inserted in the pot, as a precaution against damping. Make the soil firm around the base of the shoot. After watering the soil, place the pots on a shelf in a house with a temperature of about 50°.

SCHIZANTHUS.—When the earliest plants of Schizanthus are ready for transference, they should be given their final shift into pots about 7 inches or 8 inches in diameter. Use a fairly rich compost, such as a mixture of loam, leaf mould, manure from an old Mushroom bed, and sharp sand. When potted, place the plants on a cool base in a light house or pit. Unless it is required to hasten the plants into flower, do not employ artificial warmth, except to exclude frost. Godetias, Clarkias, and other annuals may be afforded similar treatment. These plants are all subject to attacks of aphis, which may be destroyed by light fumigations with a nicotine compound.

RICHARDIA AFRICANA.—The earliest plants of Richardia africana are flowering, and in order to keep the flowers fresh for as long as possible, the plants should be grown in a cool house. The roots need plenty of stimulants, and they must never be allowed to become excessively dry. Later plants may be hastened into flower as required by growing them in more warmth.

BEGONIA GLOIRE DE LORRAINE.—As plants of Begonia Gloire de Lorraine pass out of flower they should be partly cut back and placed closely together in a moderately warm house. Allow them to rest for a week or two by reducing the amount of water at the roots. At a still later period the shoots should be shortened and the plants placed in a moist, warm house, to encourage the growth of suitable shoots as cuttings. The roots must be watered very carefully, or many of the plants will die. Spray them two or three times daily with lukewarm rain-water. When the young shoots are large enough they may be inserted in shallow pans filled with fine sand. Place them in the propagating case and shade from bright sunshine until roots form. This Begonia may also be propagated from leaves, but this method of increase should only be adopted when cuttings cannot be procured, as cuttings always make the best plants.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

GLADIOLUS.—Corms of Gladioli should not be cleaned bare, as used to be the custom. It is far better to allow the outer skin to remain, and also any small corms that may cluster about the old one, until the time for planting both. I have allowed a large quantity of the plants, chiefly seedlings and two-year-old corms, to remain in the ground with a layer of soil spread above them after the foliage was removed. The strain at present grown is much hardier than the old seedlings from Gandavensis, and also much less liable to disease, while the plants increase immeasurably more.

SPANISH IRIS.—The shoots of Spanish Irises here are well above ground, which is somewhat weedy, though forked over in October. The weeds are mostly Chickweed, which is not easily eradicated by hoeing. A light forking is far better, and it can be done when the surface is not dry enough to permit of hoeing. A thick dressing of soot is very beneficial to the Irises, and should be applied not later than February. Flag Irises should have been cleaned and surface-dressed.

ANNUALS FOR FILLING BEDS.—It is not necessary now to apologise for utilising annuals in flower beds. Rather, the person who neglects them, and especially in these times, might be expected to make his apologies. A flower garden may be furnished very pleasingly with annuals alone. A number of beautiful kinds are tall growing and need much labour in staking and tying; those I am about to recommend need no support. I have also discontinued the growing of Antirrhinums on account of the labour involved in producing strong plants. The two plants that have given the greatest satisfaction are Godetia Schaminii fl. pl. massed with a broad band of Saponaria calabrica around it. I am using these plants for the third year in succession. Two years ago Verbena venosa was mixed with the Godetia, but the raising of the Verbena entails considerable labour, and perhaps is not worth it. A mass is very beautiful by itself. Last year a few beds here were filled with common Marigolds; and of these there are the improved varieties Lemon and Orange coloured, which are also very effective. The blue grey Cornflower is also fine, and others of blue shades to plant are Larkspur Emperor, Phacelia Campanularia, and Nigella Miss Jekyll. I strongly recommend Tagetes signata pumila for its clear yellow. This plant is easily raised in heat. April is soon enough to sow the seeds, and when they are inserted thinly the seedlings do not require transplanting till they are ready to dibble into the ground at the end of May. Silene Armeria is also a good subject, but requires some attention to associate it properly. All the Emperor Larkspurs are useful. I raise them in March in heat and transplant from the seed box whilst the seedlings are still small, after hardening them. The Nemesias are so well known as to need no recommendation. A very valuable, easy-to-produce plant is to be found in the old Ageratum mexicanum, which in rich soil attains considerable proportions. For associating with pink flowers it is admirable. Seeds sown in heat in March provide large plants by the end of May, and should the stock be limited from seed, it may be rapidly increased from cuttings taken from the seedlings and in turn from the rooted cuttings. There are also the Single Asters, either in mixed colours or separately. The seeds should not be sown till April in a cold frame, thence dibbled into flowering quarters, at a few inches apart. Though comparatively tall, the plants do not need stakes as supports. Besides these I shall note only Virginian Stocks for carpeting Gladiolus; Nasturtium Aurora (Dwarf), for very poor soils, and Tropæolum aduncum as a trailer.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, January 10, 10 A.M.: Bar. 29.5; temp. 43.0°. Weather—Occasional sunshine.

1918.

Our readers will scarcely feel surprise at the many omissions of pre-war events to be found in the Almanac for 1918 which we issue with the present number. The times are out of joint, and the immediate issues before the country far too serious to allow individuals or societies to indulge in amenities that in times of peace not only contribute to the joy of life, but in the case of the great horticultural exhibitions and village flower shows, have educational results of the greatest value. In present circumstances the labour they occasion and transport facilities needed for their staging cannot be provided; consequently the great provincial shows, such as Shrewsbury, Wolverhampton, York and Newcastle, are abandoned, as they have been since 1914, and the Chelsea and Holland Park shows of the Royal Horticultural Society, which lapsed last year for the first time, are omitted from the calendar.

It is profoundly to be regretted that the violent interruption of our everyday habits injuriously affects the gardening charities. Both the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund have been in the habit of promoting annual banquets that served to raise very large sums of money over and above the amounts obtained from the usual subscriptions and donations. The committees of these essential institutions are now deprived of this valuable source of income, whilst the need for financial help increases from year to year. In proof of this, we may draw attention to the announcement in another column of the forthcoming annual meeting of the Benevolent Institution. The highest number of pensioners the committee can recommend, having due regard to the financial outlook, is fifteen, yet the list of approved candidates includes the names of fifty-eight aged gardeners and gardeners' widows. What disappointment there must be after such an election, notwithstanding the timely help the Victorian Era and Samaritan Funds mercifully contribute to those who prove unsuccessful at the polls. If we realise these facts as we should, we shall each and all do our utmost to compensate in some degree at least for the losses our charities have to bear owing to the war, in order that the stream of charity be not dried nor the necessitous lack the kindly help that has previously been given them. This is surely a case where sympathisers would do well to purchase National War Bonds for presentation to the Funds.

In view of what has already been said, it is a source of pleasure to see that the Royal Horticultural Society will continue to hold the fortnightly meetings, thus providing the only public occasions on which gardeners may meet each other and their friends, and inspect seasonal displays of vegetables, fruits and flowers.

The food question dominates all others for the time being. The whole industry of gardening is bending itself to the task of raising increased food crops, and skilled gardeners, including both professionals and amateurs, are leading and helping the movement, first by doing all the practical work they can accomplish themselves, and secondly, by advising and encouraging the less experienced in the cultivation of their allotments and waste land. Do not let any of us for a moment lose sight of the fact that the most that can be done in these ways is the least that will suffice to solve the food problem now to be faced by our people, nor indulge in ignorant optimism that would weaken our efforts and dull our enthusiasm. These primary calls on the services of gardeners must be met fully and frankly. In addition, they must attend as best they may to the collections of valuable plants, the neglect of which would cause serious waste of accumulated efforts on the part of plant collectors and plant breeders; and give what care they can to the more permanent features of the garden, in order, for instance, that trees and shrubs may not be allowed to suffer unnecessarily in the present crisis.

So shall we tide over the period that must elapse before a satisfactory peace is established, when we may confidently anticipate an era in which gardening of all types will spread abundantly, more appreciated than ever for the calm and seductive enjoyment it will afford after a period of unparalleled unrest.

THE VICTORIA MEDAL.—Owing to the death of five holders of the Victoria Medal of Honour of the Royal Horticultural Society, the Council has appointed the following gentlemen to this distinction, viz.: Mr. W. JACKSON BEAN, Mr. F. J. CHITTENDEN, Sir HERBERT MAXWELL, Bart., F.R.S., D.C.L., LL.D., Dr. A. B. RENDLE, F.R.S., Sir ALBERT KAYE ROLLIT, LL.D., D.C.L., Litt.D.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The seventy-eighth annual general meeting of the members and subscribers of this institution will be held at Simpson's Restaurant, 101, Strand, London, on Thursday, the 24th inst., at 2.45 p.m., for the purpose of receiving the report of the committee and the accounts of the institution (as audited) for the year 1917, electing officers for the year 1918, and for the election of fifteen annuitants on the funds from a list of 58 candidates. The chair will be taken by Sir HARRY J. VEITCH, treasurer and chairman of committee, at 2.45 p.m. The poll will be open at 3 p.m. and close at 4 p.m.

TRIALS AT WISLEY.—The Royal Horticultural Society will carry out trials of the following vegetables at their gardens at Wisley during 1918:—Climbing Beans of all kinds (½ pint of smaller, 1 pint of larger), Brussels Sprouts (½ ounce), Carrots (½ ounce), Kale (½ ounce), Vegetable Marrows (one packet). The quantity of seeds required should be sent so as to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Horsley station, L. and S.W.Ry.), from whom the necessary entry forms may be obtained, on or before January 31, 1918. A trial of autumn-fruiting Strawberries will also be carried out. Twenty plants of each variety intended for trial, or a packet of seeds, should be sent to the gardens on or before February 28, 1918.

WASTE LEATHER AS A FERTILISER.—In the course of an article on the uses to which condemned Army boots can be put, the *Journal of the Royal Society of Arts* states that on account of its nitrogen content, leather waste is regarded as possessing considerable potential value as a manure. It decomposes very slowly, however, and requires special treatment to make it effective. Chrome-tanned material is found to be hurtful to plant life.

THE NORTH OF ENGLAND HORTICULTURAL SOCIETY.—This Society has just issued a "statement of affairs," and it is satisfactory to find that the deficit of £632 in the Society's accounts has been wiped out, and a credit balance obtained of £74. The acting secretary, the Rev. J. BERNARD HALL, contributes to the pamphlet a detailed programme for reconstruction after the termination of the war—a programme that suggests a very wide range of activities.

THE LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE (UNIVERSITY OF LONDON).—A course of public lectures has been arranged by the London School of Economics in connection with the Ministry of Food on "Problems of Food Control in Time of War." Another course of public lectures has been arranged in furtherance of the aims of the Imperial Studies Committee of the University on "The Empire, its Commerce and Commercial Requirements," the subjects dealt with being artificial manures, fodder, meat, fibres, timber, wood pulp and paper-making materials, leather and tanning materials. A new course of lectures on "Business Organisation" is also announced in the Department of Commerce. Particulars can be obtained from the Secretary of the School, Clare Market, W.C.

FOOD PRODUCTION IN CEYLON.—The Ceylon Board of Agriculture is taking active steps to increase food production in the island, and to that end has issued instructions and circulars to cultivators, including principal headmen, presidents of village tribunals, and local authorities. It recommends in particular the greater production of Yams, Sweet Potatos, Manioc, and vegetables of all kinds.

POTASH FROM KELP. According to an article in the *Popular Science Monthly* (New York) the undertaking recently established in California for obtaining supplies of potash from seaweed is proving so successful that one firm alone is producing three times as much potash

as was previously imported annually from Germany. The Kelp is cut by means of a reaper which cuts the weed 4 feet below the water. The Kelp is carried from a boat-harvester by a continuous belt elevator to a crushing mill. It is stated that sufficient potash is being obtained by these means to supply not only American needs but also those of all the Allies.

THE ORDER OF THE BRITISH EMPIRE. The services rendered by the Food Production Department are recognised in the list of new members of the Order of the British Empire. The Director-General, Colonel Sir ARTHUR HAMILTON LEE, K.C.B., M.P., as a result of whose untiring energies the Department has grown rapidly in strength and effectiveness, becomes a Knight Grand Cross. Mr. LAWRENCE WEAVER, who, as head of the Supplies Division, is doing a work the great value of which is highly appreciated both by the Government and by the leaders of the country, becomes a C.B.E. A like honour is conferred on Prof. T. B. WOOD, who has rendered conspicuous service to the Board of Agriculture, and who was recently appointed a Development Commissioner, and on Viscount GOSCHEN, head of the Labour Division of the Food Production Department. Among the list of Officers of the Order are Mr. CHARLES MARTIN, who, as Assistant Director of Horticulture, was conspicuously successful in obtaining the production of large quantities of last year's fruit crop; Professor E. J. RUSSELL, F.R.S., Director of Rothamsted Experiment Station, who is an active member of the Technical Advisory Committee; Mr. P. G. DALLINGER, Assistant Director of Supplies, and specially in charge of subjects relating to the Potato; Mr. THOMPSON, also of the Supplies Division; and Mr. FRENCH, who is general secretary to the Department. The membership of the Order has been conferred on the Hon. ALICIA CECIL, Assistant Director of Horticulture, whose services in building up a county horticultural organisation have been of great value to the Department; and Lieut. ASCROFT, in charge of the spraying section of the Horticultural Division.

SHORTAGE OF BASKETS AND BAGS.—Enquiries amongst fruit growers and market gardeners have revealed a very serious shortage in baskets and bags. All fruit growers, market gardeners, and others who may have baskets and bags in their possession are asked to take every precaution against loss or damage.

Photograph by E. J. Wallis.

FIG. 10.—PRUMNOPITYS ELEGANS: FRUITING BRANCH (SLIGHTLY REDUCED) FROM TREE AT VATTENDON COURT, BERKSHIRE.

(See p. 12.)

RUBBER FROM WEEDS.—A note* on the investigations carried out in Germany claims that promising results have been obtained by extracting rubber from weeds, and in particular from Euphorbia Peplus. It is claimed that 1 hectare (2½ acres) will yield 42 kilos of rubber and 120 kilos of fatty substances. Euphorbia Cyparissus promises even better results.

CANALS AND WATERWAYS.—A report has been issued on the subject of the use at present made of the canals and inland waterways of the country, by the County Purposes Committee which was asked to investigate and report on this subject in September last by the Corporation of London. The report states that a number of industries suffer through the deficiency in cheap water transport, which throws an unnecessary burden on the railways; and further suggests that the whole system of the inland waterways of the country should be brought under one control, that of the State.

OIL FROM THE BICUHYBA NUT.—The Brazilian "Bicuhyba" nut, which is found principally in the States of Minas Geraes and Espirito Santo, is understood, states the *Journal of the Royal Society of Arts*, to have been tested in the United States as an oil-producing nut. The flesh is said to contain slightly more than 60 per cent. of fats, and the shells a little more than 4 per cent. The flesh of the nut constitutes about three-fifths of its entire weight. At current prices for the Bicuhyba nuts, the cost of the extracted oil would be about 1½d. per lb., without freight.

PRICES FOR HOME-GROWN ONIONS.—The British Onions Order, dated December 24, 1917, made by the Food Controller under the Defence of the Realm Regulations, provides that no person shall sell British Onions by wholesale except to a regular wholesale dealer or to a retail dealer, and no person shall buy British Onions by wholesale except a regular wholesale dealer or retail dealer, and no wholesale dealer or retail dealer shall sell or dispose by wholesale of British Onions purchased by him except in the ordinary course of his business as a dealer in Onions. Every sale of a quantity exceeding 7 lbs. shall be deemed to be a sale by wholesale. Notwithstanding the provisions of this clause a grower whose whole crop of British Onions does not exceed 10 cwt. may sell such Onions by retail subject to the restrictions imposed by the subsequent clauses of this Order. No person (except a regular wholesale dealer or retail dealer purchasing for resale) shall in any week directly or indirectly purchase a greater total quantity of British Onions than 7 lbs. in all, and no British Onions shall be purchased, whether by one person or by several, for consumption in any household in excess of a quantity of 7 lbs. in all in any week. The maximum price on the occasion of a sale of British Onions by retail shall be at the rate of 3d. per lb. No additional charge may be made for packages or for giving credit or for making delivery. The maximum price on the occasion of a sale of British Onions by the grower shall be at the rate of £15 per ton on the basis (i) that the Onions are either loaded by the seller into trucks at the seller's railway station or (at the buyer's option) into a ship or barge not less convenient to the seller; (ii) that bags (if required) are supplied by the buyer, and (iii.) that no commission is paid. If bags are provided by the seller the price per ton may be increased by a sum not exceeding 10s., whether the bags are returnable or not; the maximum price and terms of sale shall be varied as mentioned in that clause. The maximum price on the occasion of any sale of British Onions other than a sale thereof by the grower or a sale by retail shall be at the rate of £19 per ton, on the basis that the Onions are delivered ex warehouse or market at the seller's customary place of sale and that bags are provided by the seller.

ON INCREASED FOOD PRODUCTION.

EARLY POTATOS

ALL who possess early borders should endeavour to produce as many new Potatos as possible before the old stock is exhausted. The ground should be dug deeply, and, if necessary, a dressing of decayed horse manure applied. Pulverise the soil thoroughly, and leave it exposed to the weather until the time for planting arrives. The seed tubers should be selected at once and placed in shallow boxes to sprout. Choose moderate-sized tubers, and let them be fully exposed to the light in a place that is not too warm, or exposed to cold draughts. A room or shed having a temperature of 45° is suitable. At the time of planting the ground should be forked over and trenches made with a spade 6 inches deep. A layer of well-decayed leaf mould or the material from a spent Mushroom-bed may be placed in the bottom of each trench to a depth of 2 inches, and as planting proceeds place the material carefully around the plants with the hands. Allow at least 2 feet between the rows and 1 foot from plant to plant. When the young shoots begin to show through the surface, careful attention is necessary to protect them from excessive cold. Dry soil may be placed around the stems as they push through the ground, or the borders may be covered with thatched hurdles, which are easily removed when the weather is warm. Neglect of covering soon results in the destruction of a valuable crop. One of the best Potatos for early cropping is May Queen. A few early Potatos may also be grown close up to a south wall on which fruit trees are trained. Soil for the purpose may be placed just under the wall, and removed as soon as the crop is lifted. Old soil which has been used for growing Melons, if exposed to the weather during the winter, will be suitable for the purpose. *J. D.*

MANURING FOR POTATOS (see p. 9).

Japonica expresses doubts as to the wisdom of autumn digging and manuring of ground of a distinctly porous nature intended for a Potato crop. For many years I grew a considerable quantity of both early and late Potatos on such land, and was forced to the conclusion that it was not a profitable method, and, had labour permitted, I would have delayed all digging and manuring of this light soil until the early spring, but this could not be done. My method for the Potato crop was to bastard trench the ground during the winter, as circumstances permitted, and at planting time to spread over it a quantity of well-decayed manure which had been especially reserved for the Potatos.

The sets were planted in drills, and I found that not only was the manure well mixed with the soil through the drill making and filling, with, later on, hoeing and earthing up, but that it remained just where it was wanted, in reach of the Potato roots. An additional advantage was that by this system the crop did not suffer from summer droughts as was the case when the manure was buried under the top spit in the orthodox manner.

I am convinced that the often-repeated advice to spread chemical manures along the bottom of Potato drills is a wasteful mistake, for long before any roots can get to it all the virtue of the sulphate of ammonia and superphosphate of lime, which in these days form the base of Potato manures, will be washed by rains into the sub soil. A far better plan is to delay the application of chemical manures until the haulm is 4 inches or 5 inches high, and then to spread it alongside the rows and hoe it in as soon as circumstances permit. A generally suitable mixture for this purpose would be sulphate of ammonia 3 parts, superphosphate 5 parts, well mixed and spread at the rate of 3 ounces to 4 ounces to the yard run between the rows.

GROUND OPERATIONS.

THE correspondence on this subject makes it abundantly clear that no hard-and-fast rules can be laid down in gardening. The measure of success depends on local conditions and the practitioner. Many of us have found that it pays best to dig certain heavy soils as early in the winter as possible, throwing the spits up roughly to allow frosts and winds to exert their beneficial influences in disintegrating the lumps, so that when seed time comes the clods fall to pieces, giving that fine tilth which the old-time writer ever insisted on, and which is so essential to perfect seed germination and the raising of healthy and vigorous seedlings. But in opposition to this generally practised method, Mr. Edwin Beckett tells us that towards the end of February is the ideal period for digging heavy, tenacious soils, and we know what he has accomplished by that method, so that in his particular case it is no doubt correct. But I see several objections where a considerable area of heavy land is so treated in these days of labour shortage. The period for cultivating heavy soils is generally strictly limited, for if not caught when at the right condition they will "set as hard as bricks," and even a moderate tilth becomes an impossibility, and one may have to wait weeks for the right weather conditions to again occur. Consequently, the seed sowing would be late if all the required ground had not been dug, and except in favoured instances this would be the case. Many light soils may be dug, levelled, and sown within a couple of days of rain, even in the early spring, when the air is not so drying as it becomes later in the season. *A. C. Bartlett.*

—— Having had a few years' experience in the cultivation of Onions on the heavy clay soil of Middlesex, it may interest Mr. Davis and others to know that the following method of preparing the beds has, without exception, proved the best means of obtaining good results. Before the winter I incorporate with the heavy soil ashes from the garden fire, spreading them over the ground to a depth of 2 inches. The soil is thrown up roughly in digging. The beds are 5 feet in width at the base, sloping to 4 feet wide on the surface. An alley is formed between the beds 1 foot wide and 1 foot in depth, and the soil from the gully is thrown on to the beds, leaving it rough, to be disintegrated by the weather. The clods break readily after they have been subjected to frosts, and when the surface has been made fine again, the beds are in condition for the final preparation in the spring, when I sow a mixture of soot and salt lightly over the surface, and finish off for the planting of box-sown Onions, or for sowing the seed direct, as may be, drawing the drills at right angles to the alleys. Heavy soil prepared roughly with the ashes and afterwards finished off with a light coating of lime I have found to answer for both Leeks and Cauliflowers raised under glass. *W. J. Taylor, Framewood Gardens, Stoke Poges, Bucks.*

PREPARATION OF FRESH ALLOTMENTS

I LIVE in a large manufacturing town where plots of building land and other almost derelict spaces have been, or are being, laid under contribution for allotments. They are prepared for the reception of crops by thorough working of the soil, usually bastard trenching. Unless the turf be badly infested with Coltsfoot, Sorrel, or Couch Grass it is dug in, for if there is any natural fertility in such soil it resides in the turf. The method adopted is to break it up with the spade and place it between the subsoil and the surface layer as the work proceeds. It is unlikely that the supply of manure will be equal to the demand, therefore the needs of those crops that require it should be met first. Onions, Potatos, Peas, and Beans require much more manure than the Brassica family. A medium that is too rich will produce loose Cabbages and Savoys, and leaves at the expense of flowers in Cauliflowers, and it is one of the causes of loose Brussels Sprouts. The succulent growth induced also renders those that have to pass the winter liable to suffer from the severity of the weather. Farmyard manure, in addition to supplying the elements of fertility, adds humus, which improves the physical condition of the soil. Humus is necessary in some form, therefore where manure is unobtainable, a substitute must be sought. There are many; decaying leaves will serve the purpose well, and may be incorporated with the soil now. Spent hops are useful, and can be obtained cheaply from a brewery. Leaves and tops from vegetable crops, if free from disease, should be placed to rot down, and be dug in as required. It should be borne in mind that these materials are not equal to manure. In all cases they should be supplemented by artificial fertilisers, applied nearer cropping time. It is difficult to convey the proper meaning by suggesting the weight of manure to apply to a definite area of soil. The different samples vary from wet to dry, and ratio of manure to straw. A dressing for crops that require an abundance of manure should be four inches thick. Half that thickness is sufficient for the less aggressive kinds. The work of digging should now proceed with all possible haste. If the soil is left as it falls from the spade the weather will exercise an ameliorative influence. Many of the war-time plots are as badly in need of lime as of manure. It is well known that to mix these two substances is bad practice, but they can be applied at the same time by spreading the lime over the surface after the manure has been dug in. It will gradually work down, sweeten the land, and not interfere with the proper action of the manure. Air slaked lime should be employed at the rate of one stone to 40 square yards. No attempt should be made to work the soil further until the middle of March, when it will benefit by being forked over. As it dries after that date, early vegetables may be sown. In the South of England it may be profitable to sow earlier, but in our dour Northern climate I have never known it to be so. *Geo. H. Copley, Horton Park, Bradford, Yorks.*

PARSNIP CANKER.

SERIOUS losses were caused to Parsnip growers last season through the disease known as Parsnip canker. The subject has since been investigated by the Food Production Department, and it has been found that the trouble is not caused by a special fungus disease, but is due primarily to the presence of superficial cracks which are formed in the shoulder of the Parsnip root during the growing season. The cracks are formed in great abundance when a spell of wet weather follows a dry period during August and September. In the case of Carrots and Turnips, somewhat similar cracks become healed over by the formation of a layer of cork, but the Parsnip root is unable to form this protective layer, with the result that insects, fungi, and other soil organisms easily gain entrance and set up decay. In the most badly affected districts the trouble has probably been aggravated by faulty culture, such as over-manuring and lack of lime. In order to reduce the amount of cracking to a minimum it is advisable (1) to select moderately good soil where liming has not been neglected, and (2) to sow late—the end of April rather than in February or March. A dressing of salt previous to sowing, 5 cwt. per acre on heavy soil and up to 10 cwt. per acre on light land, would also probably prove beneficial.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE DEFERTILISATION OF FLOWERS BY INSECTS (see p. 4).—The failure of flowers to get fertilised may be due to a variety of causes, as is well known to gardeners, but I do not recollect anyone having described the cause mentioned by Mr. Brown. The depollination of flowers, used by the same author, is the more correct term for the action of insects, because those flowers which are habitually self-fertilising take the earliest opportunity of placing the stigma in contact with the pollen, and after the pollen tube is well protruded and fixed, the depollination of the flowers would be difficult or impossible for insects, and fertilisation follows with certainty. There are, or were, many self-fertilising varieties of Pelargonium zonale and its hybrids with P. inquinans, also of other species, which regularly set fruit in the open or under glass. I have, for many years, watched the pollen-devouring Syrphidae, and they are numerous in individuals and species. Pollen is scarce in the highly developed flowers of Pelargonium in this country at all times, except from June to September inclusive. At other times only a few of the 5-7 antheriferous stamens produce pollen, or none at all. The filaments seldom even elongate, in species other than the zonal group, when the light and heat are not equal to the requirements of the plants. The pollen devouring insects are by no means confined to the Syrphidae, for other Diptera and beetles are also guilty. Most honey-bees are assiduous pollen collectors, and probably no sample of honey in this country is without pollen in its contents, while the proportion to honey is often large. When pollen is plentiful the Syrphidae fertilise the flowers as well as eat the pollen. I believe they are the principal insects which set the flowers of Veronica speciosa, its hybrids, V. Colensoi, V. pimeliodes, V. parviflora, and many others. Some years ago very diligent search failed to find pollen in the anthers of Saxifraga cernua, visited by Syrphidae and other Diptera, yet I collected individual grains of pollen, belonging to several other genera, on the petals and interior of the flowers, so that, in summer at least, the insects do not manage to devour all the pollen they carry away by design or accident on their feet and hairy bodies. *J. F.*

CUPRESSUS FORMOSENSIS.—In reference to Mr. Elwes' letter in your last issue, I may mention that this plant has not proved hardy at Aldenham, having been either actually winter-killed when about 4 feet high, or so severely injured by frost as to be rendered worthless. This, of course, is quite consistent with its having flourished in the milder climate enjoyed by my friends Sir Herbert Maxwell and Mr. F. R. S. Balfour, at Monreith and Dawyck respectively. I cannot believe that it would ever succeed at Colesbourne, where your correspondent Mr. H. J. Elwes has to contend with worse soil and climate than fall to my lot in Hertfordshire. Although a close, heavy clay like mine is one of the worst locations for all but a small minority of Conifers, it suffices for about half a dozen of the genus Pinus, such as P. sylvestris, P. Cembra, P. austriaca, which are pretty satisfactory with me. No Picea or Abies, however, can be depended upon to make good growth after their roots have got out of the mould in which they have been planted into the virgin clay, though for the first ten or fifteen years of their life they may show a promising appearance. Larches, if the ground round them be well broken up, and if (a very big "if" in our case) they escape serious injury from spring frosts, make useful enough timber, but I doubt if they would ever make very old or fine specimens. Indeed, I should neither get nor deserve the many interesting visitors whom I have the pleasure of seeing at Aldenham, if, as in many gardens, a pinetum were the principal feature. *Vicary Gibbs, Aldenham, Elstree.*

THE STORING OF APPLES.—I was interested in Mr. Beckett's remarks on p. 8 on the storing of Apples, and his comment on what he calls the ignorance of "the most elementary rules governing the keeping of fruit." He proceeds to attack the laying out of the fruit in single layers, remarking that, at Aldenham, he does not hesitate to "pile the fruit one on top of another, even to six or seven layers," emphasising, however, the necessity of their being perfectly sound, and bringing, as a proof of his case, the condition of the stray fallen Apples found during winter under the leaves. On p. 5 Mr. Jas. Hudson (of whom it is no disparagement to Mr. Beckett to say his advice is equally entitled to respect) states, in his remarks on the fruit room, "Do not let the fruits touch each other if it can be prevented," and again, "Be careful in handling, and take up each fruit separately, so as not to mark it." Thus we have two extreme views from sources both of which are entitled to the highest respect. Mr. Hudson, I admit, does not refer specially to Apples, as Mr. Beckett does, but, as his remarks are general, it may be taken that he includes that fruit. Alas! who shall decide when such authorities differ? Not the present writer, for he only follows from afar, but in view of the importance of the storing of fruit in the coming season I humbly beg to draw your attention to these two statements. *"Puzzled."*

SALVIA SPLENDENS VAR. PURPUREA.—In the *Gardeners' Chronicle* of December 1, p. 218, I drew attention to a ruddy purple form of Salvia splendens which had originated as a sport in the Cambridge Botanic Garden. Mr. Watson, of Kew, to whom I have forwarded a specimen, is well acquainted with it. It was sent to Kew from a Continental nursery, probably that of Messrs. Haage and Schmidt, and it is included in their catalogue as *S. splendens* var. *purpurea*. Mr. Watson informs me that it comes true from seed. The above information I give for those who may be interested. The origin of the Continental plant appears to be unrecorded, but as the same thing has appeared as a sport at Cambridge it probably originated in the same way. *B. Lewis Lynch.*

SOCIETIES.

GENERAL BULB GROWERS' OF HAARLEM.

We are informed that the following awards have been made by the respective committees of the General Bulb Growers' Society of Haarlem, Holland, during July, August, September, and October, 1917:—

FIRST-CLASS CERTIFICATES.

Gladiolus primulinus Scarletta, orange-red shaded lined red; Mrs. Velthuys; Mrs. Frank Pendleton, creamy-white shaded rose, with purple-red spots; Dahlias: sulphurea (decorative), sulphur-yellow; Vaunbaak (decorative), scarlet and orange; E. F. Hawes (Cactus), dark velvety purple; Velours d'Utrecht (single), dark velvety purple; Franz Ludwig (Paeony-flowered), clear mauve; and Pres. Washington (decorative), lilac-rose.

AWARDS OF MERIT.

Gladiolus primulinus Hesperia, salmon; G. p. Laetitia, salmon-rose; G. p. Salmonea, clear salmon-red; G. p. Jane, yellow with clear salmon markings; G. p. Maiden's Blush, salmon-rose spotted white; G. p. Sylphide, apricot, spotted clear yellow; G. Lena, purple, spotted brown; G. Lily Lehmann; G. Red Canna, dark purplish-red; G. Yellow Standard, yellowish green shaded lilac; G. Goliath; G. Mrs. K. Veltkuys; G. Prince of Wales; G. Aurora; G. Golden West; G. Mr. Mark; G. Liebesfeuer; G. War; G. Nora; Dahlias: Penserosa (decorative), lilac-rose; La Reine (decorative), milk-white; Renselaer (decorative), dark velvety-red; Moon (Paeony-flowered), dark brown; Melody (Collerette), clear purple-violet, collar pure white, from seeds; Cuneta (decorative), lilac and creamy-white; Mont Blanc (decorative), pure white, shaded rose; Adagio (Collerette), rose-violet, collar cream; Orange King (decorative), amber and old gold; Soleil d'Octobre (decorative), clear yellow; Purity (decorative), salmon-red and lilac with apricot-coloured centre; Rigida (decorative); Yellow Star (decorative), sulphur-yellow; Mrs. White (decorative), rose-carmine; Jo Ballego (decorative), orange; Salmon Queen (decorative), salmon; Dream (decorative), apricot with amber; Carmen Sylva (decorative), salmon shaded yellowish lilac; Brandaris (garden Cactus), clear yelow; Mea Vota (decorative), clear orange-shaded apricot; Ada Finch (Anemone-flowered), white and yellow; Marie Cats (decorative), pure white, centre shaded green; Mars (decorative), carmine shaded amaranth; Sandlower (decorative), dark yellow; Buff Queen (decorative), old gold shaded with cinnamon colour; Begonia surpasse Zeppelin, clear orange-red.

CERTIFICATES OF THE HAARLEM TRIAL GARDENS.

Anemone japonica Geante des Blanches; A. j. Loreley; A. j. Queen Charlotte; Dahlias: Burgemeester de Gyselaar; Brennende Liebe; von Hindenburg; Halley; Thorbecke (Paeony-flowered), pure yellow; Dream (decorative), apricot with amber; Artistique (decorative), rosy white; Porthos (decorative), lilac; Pink Perfection (decorative), salmon-rose; Louise Germ (decorative), yellow with apricot; Yellow Star (decorative), sulphur-yellow; Requiem (decorative), velvety-brown; Kalifsdochter (garden Cactus), carmine rose; Aria (Collerette), rose, collerette white; Melody (Collerette), purple, collerette white; Senate (Collerette), orange scarlet, collerette yellow; Velours d'Utrecht (single), dark velvety-purple; Crawley Star (Star), lilac rose and brown; Golden Glory (small-flowered), clear orange; White Pearl (decorative), pure white; Titanic (decorative), lilac; Worth Star (Star), rose.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 6.—*Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. Cypher, A. G. Ellwood, A. B. Handley, A. Hanmer, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, W. Shackleton, H. Thorp, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Helen Langley The Knowle var. *Dusseldorfi Undine* × *Myra Peeters*), a large white flower with purple marks on the lip, from JOHN HARTLEY, Esq.

AWARDS OF MERIT.

Brasso-Cattleya Peerless (*Digbyana gigas* × *Fabia*), *Odontaglossum Gladys* (*cirrhosum* × *crispo-Herrenianum*), *Cymbidium Schlegelii Ashworthii* var., *Odontioda Mars*, and *Renanthera Clarkei*, all from R. ASHWORTH, Esq.

Cypripedium Formidable (*Mastersianum* × *Hellwigianum*), *C. Upert Alpha*, and *Laelio Cattleya Jacinth* (*C. Triomae* × *L. C. Pizarro*), from S. GRAPRIX, Esq.

Cypripedium Col. Hennah (*Leeanum Clinkaberganum* × *Antinoas*), from the Hon. ROBERT JAMES.

Laelio-Cattleya Bella alba Beardwood var., from Col. Sir J. RUTHERFORD, Bart., M.P.

Obituary.

OSCAR H. WILL.—In the course of an obituary notice of the late Oscar H. Will, of the firm of Oscar H. Will and Co., Bismarck, N.D., the *American Florist* (September 15, 1917) refers to the fact that it is due to Mr. Will's work in plant breeding that North Dakota and Montana are now able to produce between 10,000,000 and 20,000,000 bushels of corn annually, where 20 years ago they produced only a few hundred bushels. Mr. Will's experiments were based on varieties of corn which he obtained from the Dakota Indians, and from these varieties he raised a number of strains suitable for growing in the climate of the N.W. States.

CROPS AND STOCK ON THE HOME FARM.

OATS.

FROM a utilitarian point of view the Oat crop is ahead, even of Wheat, in the many uses to which it can be applied in normal times. As food for horses in hard work good Oats are the mainstay. For cows in milk no food is better than Oats when crushed for giving an increase of milk. For calves, too, Oats are valuable feed. For ewes and lambs they are valuable, as they increase the quantity of milk in the mother. When fed to poultry nothing is better for laying hens, and when ground whole for fattening chickens, and especially turkeys. Oats aid considerably in putting on flesh of high quality, particularly white in colour and fine in texture. Oats are also good food for pigs, either used whole or as meal. The straw is valuable as fodder for cattle; some farmers even use Oat straw in the place of Hay for horses, but I do not think it has the same value. The straw is also fed largely to store cattle in winter, and appreciated by the animals when harvested in good condition.

With good cultivation Oats yield heavily, although no kind of cultivation—no matter how good—can assure good quality of grain if the weather is unfavourable in the growing season or at harvest time. No cereal crop is so amenable to the effect of stimulative food as the Oat. Sulphate of ammonia sown at the proper time gives beneficial results, and for quite a moderate outlay. Nitrate of soda is probably more beneficial, but obtaining this fertiliser in bulk is now out of the question.

Where grass land is to be broken up in the spring Oats will give a better return than any other crop, certainly more than any other cereal. The roots of the Oat plant appear to revel in newly broken up grass, partly decayed, especially when wireworm is not present.

The yield of the Oat crop varies, like all cereals, according to circumstances, including weather and method of cultivation. The heaviest and best quality crops are, as a rule, obtained from early sowing, although even this method may be good or bad, according to circumstances such as situation, heavy and light soil, wet and dry sites. In the South of England some of the best Oats are grown from seed sown in February, especially on chalk soils, whereas if the same land was sown in April and a dry season followed, the growth would be poor and the crop and quality inferior. In chalk soils, therefore, an early start is imperative. With ordinary cultivation the Oat crop varies in its yield from 30 to 60 bushels per acre. When the latter figure is obtained, and that is not excessive—Oats of good quality weighing not less than 40 lbs. per bushel—it is easily seen that the Oat crop is remunerative at the present Government price of 43s. 9d. per quarter. Oats may be grown in succession to many other crops. Perhaps the best results are obtained after a good crop of Wheat, with the land clean and in good heart.

Following a Wheat crop, the ground can be ploughed early in autumn and a good surface tilth obtained. The Oats are then sown on a stale fallow in February without any further ploughing preparation. Good Oat crops may also be obtained after Potatos or Mangolds. Oats are also usually a success after sheep fed roots or Rape, especially when sown early, the ploughing being done quickly behind the sheep in March. The freshly ploughed land usually provides a good tilth for the seed.

As a rule Wheat is sown on Clover ley, although some prefer Oats for this rotation, because, when the leys are reserved for winter ploughing, it provides work for the horses when the fallows are too wet to be interfered with; the ley ground is then in good condition by the action of frost at the end of February or early in March to receive the Oats. The method of sowing Oats varies in different localities; some farmers still favour hand-sowing, and with marked success, but the broadcaster machine, which covers a space of 20 feet, has largely taken the place of hand-sowing, especially where the acreage is large.

Twenty acres can easily be sown in one day with two horses; one horse will drag one 16-feet machine on a flat surface. Many adhere to the drill, and for even distribution of the seed no method is better, but in some soils the necessary preparation of the land is not easy, and all too often, when the necessary tilth is obtained, rain falls, and sowing has to be deferred for days or even weeks. I am a strong believer in the Massey-Harris Cultivator, with a seed-box attached, which drops the seed evenly in front, and the action of cultivating the soil partly buries the seed at a uniform depth. How much harrowing is required after sowing the seed depends upon such circumstances as light or heavy soils, and of committing the seed in the various manners indicated. After the drill and cultivator once harrowing is sufficient if there is a good surface tilth. For reasons of space I must postpone further remarks on Oats until next week; in the meantime, do not let us overlook the extreme value of the crop. *E. Molyneux.*

LAW NOTE.

YEW POISONING OF ANIMALS.

THE death of grazing animals through eating the leaves of Yew trees has given rise to many law suits. It has been established for many years that where the tree stands on ground belonging to someone other than the owner of the field in which the animal was grazing, but overhangs such field so as to bring the branches of the Yew within the reach of the animal, the owner of the tree is liable for the injury done to the animal.

It is interesting to learn, however, from an article in *Stubbs' Gazette*, of December 26, 1917, that an exception to this rule of liability is to be found where the owner of the Yew tree is the landlord of the field in which the animal is grazing. This was established, it seems, in the Appeal Court last November. The plaintiff had taken from the defendant the lease of a field adjoining other grounds owned by the defendant. A mare was put out to grass in this field, and ate, with fatal results, of a Yew tree which overhung the field, but was standing in the landlord's garden. It was held that as the defendant could not prove that the Yew was not already overhanging the field when he took it, and that therefore he took the field with his eyes open, as it were, he must take the responsibility for whatever danger existed there.

It may be enquired whether a landlord is under no obligation, when he lets a piece of land, to see that there is nothing on his own land which will be injurious to that which he has let. It appears that the answer is in the negative; the contention being that a tenant must use his own eyes, and judge for himself when viewing the land before taking a lease whether or not there is anything on it, or in close proximity to it, which will be dangerous or noxious. If the plaintiff in the case referred to took a field with a poisonous shrub near it, he could not afterwards claim damages because the shrub caused injury to his mare.

Had the circumstances been slightly different there would have been another line of attack open to the plaintiff, and that is, that the tree was not overhanging the field when he took it, but became overhanging during his tenancy. In point of fact the plaintiff was not able to pursue this line, as he had no evidence to produce; but the opinion was expressed in the Court of Appeal—though not given as a decision—that probably, in the case of the danger having arisen after the lease had been taken, the defendant would have been liable for the death of the mare, in spite of his favoured position as the landlord of the plaintiff. It is a pity that the absence of evidence prevented the Court from coming to a decision on this point, as it would have proved a valuable precedent.

BASIC SLAG FOR TOMATOS: *C. W.* Basic slag is not quickly soluble, and would not be suitable as an ingredient for manure water. Your suggestion to mix the slag with the soil of the border should be adopted, applying it at the rate of 4 oz. to the square yard. Superphosphate is a quicker-acting phosphatic manure, or you may use bone meal with the compost.

FEEDING FORCED BULBS: *B. J.* The quality of the flowers in Daffodils, Hyacinths, and Tulips depends in a great measure on the cultivation the plants received in the previous year, and on the character of the weather. If the conditions were not favourable in the previous season the flowers would be of inferior quality, whilst small-sized bulbs often give small flowers. In the case of well-ripened bulbs of first size weak liquid manure may be given from the commencement of forcing, but it would not be necessary if fertilisers were added to the soil. In the case of Daffodils a much greater factor in success is attention in watering. There should be no stint of moisture in the atmosphere or at the roots of the plant. In the early days of Daffodil forcing great losses were sustained owing to insufficient supplies of root-moisture and air-moisture.

LICENCE FOR SEED EXPORT: *J. W. T.* Write to the Board of Trade, Export Department, Whitehall, London.

MOUSE: *Pomona.* The animal is an albino short-tailed field mouse or field vole (Arvicola agrestis).

PEARS BECOMING SOFT AND WOOLLY BEFORE RIPENING: *H. J. G.* There are a few varieties of Pears which go soft and rot inside before they are obviously ripe, notably Jersey Gratioli. These should be used when they are just off the hardness of unripe fruit. But if all your varieties behave the same, the complaint is not a familiar one. It may point to a lack of moisture in the soil in the latter part of the season, and you might try a few experiments on different rows or trees, as follows: (1) A good mulching with rotten farmyard manure; (2) a dressing of 4 lbs. of nitrate of soda or sulphate of ammonia (the former from choice, if obtainable) per square perch of land; (3) the same quantity of agricultural salt; (4) liberal watering when the fruit is maturing.

THE PROPAGATION OF CERTAIN HARDY TREES AND SHRUBS: *H. W.* Aralia chinensis and A. spinosa may be increased by seeds, but seeds do not always mature in this country. Both species may be propagated by suckers as well as by cutting the stout roots into pieces 3-4 inches long and planting them in boxes in gentle warmth during February or March. Daphne Mezereum is raised from seeds, which are best sown immediately they are ripe. They germinate freely in a moist soil out-of-doors. Cold, wet, heavy soils are not suitable. Hamamelis arborea and H. japonica Zuccariniana are generally increased by grafting in February and early March on well-established plants of H. virginica. Select well-ripened scions and place them in a warm case and syringe the shoots overhead occasionally. H. virginica, the common species, is raised from seeds sown out-of-doors. The two first named cannot be depended upon to come true from seeds, which often take a year or more to germinate. There is no book dealing exclusively with the propagation of hardy ornamental trees and shrubs, but the propagation of many of the species is dealt with in general works on hardy trees and shrubs.

NOTES FROM KEW.—I.

UNDER the above heading, and by desire of the Editors, it is proposed to describe in the following series of articles some of the objects of interest to be seen at Kew in each month of the year, and thereby to satisfy, in some degree at least, the desire expressed by Sir Herbert Maxwell in the concluding article of his most interesting series of letters on "A Galloway Garden."

In January, even Kew is under the spell of winter. Plants generally are at rest, though every week produces evidences of the spring revival, and a walk through the grounds reveals, to the gardener especially, much that is interesting. Rhododendrons everywhere show promise of a great display of bloom. The weather last year was to their liking, plenty of rain and not too much sunlight and heat, affording just those conditions which these mountain shrubs enjoy. The plants in the Dell look exceptionally promising, and so do the Azaleas in the glade near by. Chinese Rhododendrons now occupy a separate area near King William's Temple, and they also flourished last year. It is, of course, too early to pass judgment on their horticultural qualities, especially with respect to hardiness. Many of the species are growing happily in the open in ordinary conditions at Kew, and they are worth watching by gardeners interested in what will most likely eventually prove the most valuable of the evergreen shrubs from China.

The most striking object in the Berberis Dell is the new flagpole, which is waiting to be set up where the old one stood. It is a magnificent "stick," as the Canadians call it. Popular feeling favours its erection in time to carry the flag of victory. Who will set it up, and how it will be done, are questions often asked.

Kew is a museum of living plants, and, like all museums, it contains a large number of objects that possess no apparent interest. Gardeners have been known to ask why so many poor-looking things are cultivated, and it is not always easy to furnish a convincing answer. Some plants carry a good character in their faces, but a great many possess no charm for the eye: their labels are the key to their virtues. Sir Joseph Hooker, when he was director, loved to walk in the gardens and to talk plants, and even he often failed to recognise the cultivated examples—their labels were needed to set him discoursing on their botanical or economic peculiarities. In his younger days he was somewhat prone to take a detailed interest in matters cultural, but he learned in time that the art of the grower is not acquired by collecting nor yet by studying plants botanically. Few botanists have ever shone as cultivators.

Collections of species representative of the genera and orders of the vegetable kingdom are grown at Kew, whereas in non-botanical establishments only attractive plants find a place. There are, for example, over a thousand species of Orchids in the living collection at Kew, not a quarter of which number would be passed as good garden plants. And this is more or less true of the other collections. There are fanciers who cultivate species and varieties in the spirit of the collector of postage stamps, and they appreciate the "botanical" plants that are grown at Kew.

Cape Heaths were an attractive feature in winter at Kew thirty years or so ago, when probably 200 species and hybrids were grown in the Cape House. They have all disappeared, partly because the plants are no longer in fashion, but chiefly, so far as Kew is concerned, because the art of growing them has gone. The collection was a good one sixty years ago, as is shown by an illustration in *Wanderings at Kew*, by P. H. Gosse, published in 1856, who speaks of the collection of Heaths of the Cape of Good Hope as being a very fine one. He also says that few plants were at that time more generally cultivated, and, taken as a whole, perhaps none were more beautiful. Tricky plants to grow these Heaths are, especially the hairy-leaved, hard-wooded species. In their best days only a few gardeners really succeeded with them, they are so exacting with respect to water at the root and ventilation. It is a pity they have lost favour, though they would have a poor chance in these times of hustle and high-pressure culture. A few species are still grown at Kew, chiefly such as those grown for market. The curator of Kirstenbosch, Cape Town, ought to get together a collection of those Heaths, which are the Rhododendrons of South Africa.

Hard-wooded greenhouse shrubs less than fifty years ago occupied a prominent place among favourite garden plants. It is surprising how many good things have entirely gone. In the 'eighties there was plenty of interest in indoor plants. Nurserymen were keen on them, many good private collections were kept up, and many visitors to Kew displayed a knowledge and love of them which rarely shows itself now. Mr. Elwes keeps the flag flying, and Sir Frederick Moore, of Glasnevin, and Mr. Lynch, of Cambridge, retain still a liking for a good indoor plant that is not an Orchid. Nurserymen cannot afford to stock plants that nobody wants, so they have ceased to bother about Aroids, Palms, Ferns, Dracaenas, Crinums, Marantas, Crotons, Dipladenias, Boronias, Aphelexis, Correas, and the many other champions of former days. Were it not for Orchids we might look upon indoor decorative gardening as having parted with all elegance and taste.

A tour through the plant houses at Kew even in January affords much enjoyment to those who have eyes to see and are not without knowledge of the vegetable kingdom. The great Palms, Cycads, Pandanads, and other striking representatives of tropical vegetation appeal to most people: the collection of Agaves, Aloes, Cacti, and

[*Photograph by E. J. Wallis.*

FIG. 11.—BUDDLEIA ASIATICA: FLOWERS WHITE. (See p. 22.)

other dry-country plants; the Ferns, of which the number of representatives is very large; and the less tropical trees and shrubs in the great Temperate House are all national treasures in their way, and ought to be as greatly prized as the collections in the British Museum, which have been the subject of discussion in the Press lately.

The Calanthes, Laelias, and Cypripediums in the Orchid department are good, though the fogs in the first week of the present month injured them. Ipomœa Briggsii, with its long sprays of bright crimson flowers, is the best climber in the T Range, as Brownea Crawfordii is the most showy of the big shrubs in the Palm House. Acacia dealbata, Luculia gratissima, and the Malayan Rhododendrons are the pick of the plants in flower in the Temperate House. A noteworthy winter greenhouse plant is Begonia Sanderae. It is in the way of B. semperflorens magnifica, but shorter, and the flowers are a glowing scarlet. This is a new hybrid, which was sent by Messrs. Sanders from the Bruges nursery, together with other precious refugee plants, soon after the war began.

There is always a show of flowers of some kind in No. 4, but January and August are its two "off" months. Veitch's winter-flowering Begonias (socotrana × tuberosa) were the glory of the house throughout December, and they are still good. The secret of their cultivation is to keep them free from mite, and this is easily done by sulphur fumigation, using for the purpose the vaporiser and preparation supplied by Mr. J. T. Campbell, Manchester. Until we were made acquainted with this mite destroyer these Begonias, as well as many other indoor plants, were often spoilt, the watering-pot, ventilator, or defective fertilisers being suspected. Begonia socotrana is still worth a place as a winter-flowering plant. So also is the Kew type of Primula sinensis.

Pycnostachys Dawei is good this year, but Coleus thyrsoideus is unhappy, whereas formerly it was one of the winter successes at Kew.

Buddleia asiatica (see fig. 11) is worth knowing as a greenhouse shrub. It is grown in pots outside all summer, and housed in October, coming into bloom in December. The flowers are in catkin-like racemes, white and deliciously fragrant. Another good winter plant is Columnea magnifica, as it is easily grown in a cool house or frame, makes shapely pot specimens in a year, and is in flower for about two months. Bomarea patacocensis is in bloom, its rope-like stems twining about the girders of the roof, from which the flower-heads hang like clusters of red Honeysuckle.

Last year some of the flower-beds and borders were devoted to Cabbages, Turnips, Beet, Kohl Rabi, Cauliflowers, and other vegetables, which were sold to the employees, who were thus provided with fresh, wholesome vegetables at reasonable prices. It is intended this year to grow more, and altogether about 6 acres of lawn and flower-bed will be ploughed or dug up and planted with vegetables. The whole of the flower garden in front of the Palm House will be used for a crop of Onions. *W. Watson.*

WART DISEASE OF POTATOS.

A VALUABLE SUMMARY of the trials of varieties resistant to wart disease is contained in the *Journal of the Board of Agriculture.** As is now well known, certain varieties of Potato are so susceptible to this disease that it is useless to attempt to grow them on land infected with the species of the wart disease organism, Chrysophlictis endobiotica. By a stroke of even-handed justice which nature by no means always displays, other varieties are entirely resistant to the disease. It is therefore possible to continue to use land infected with the disease for the cultivation of the Potato crop. Needless to say, the use of infected land, even when immune varieties only are cultivated, is always likely to lead to the spread of the disease, for immune varieties grown on infected land, although they have no disease in them, may well carry the spores of the disease on their coats. Mixed with the dirt on the lifted tubers, these spores will infallibly lead to an outbreak of the disease if they are planted with the immune seed. This indeed is one of the chief means whereby the disease has spread, and is spreading, and it will require well-considered and resolute action if the distribution of this disease throughout the whole of the country is to be prevented.

There is no need to insist upon the extreme importance of being prepared for such an eventuality, and evidently the existence of immune varieties enables preparations to be made. It is evident that if no risks are to be run provision must be made for there always to be available more than enough seed, of immune varieties, to plant the whole of the areas infected with the disease. This evidently means the working up of very large stocks of the best varieties of "immunes."

The sceptical may be inclined to ask, "How do you know that an immune variety will always remain immune?" Although it is not possible to return an absolutely confident answer to this awkward question, yet it is encouraging to observe that all the evidence so far obtained goes to show that immunity is an absolute, and not a relative, quality. An immune variety remains immune—so far as experiments go—even when it has lost vigour by having been grown in unsuitable soil or districts. Of early kinds, the number of immune varieties is none too many. They include AI (Sutton), a round, medium-sized, white-skinned, yellow-fleshed variety, a moderate cropper. Early Prolific, or Early Border, is similar to AI. Resistant Snowdrop (Dobbie), a kidney with white skin and flesh, a good cropper of fairly good quality, and Edzel Blue, a round, with coloured skin, white flesh; a good cropper and of excellent quality, recommended highly for gardens and allotments, but we believe that there are few, if any, tubers of this variety to be had at present.

Seedling No. 1 (Gardener) and Crown Jewel (Toogood) are other early varieties. Of second early varieties tested by the Board of Agriculture at Ormskirk in 1917 and found to be immune, the following may be mentioned:—King George, a heavily cropping variety, but not of the first quality; Great Scot, too well known to require description here, and later than King George; Sir Douglas Haig and Southampton Wonder, similar to Great Scot; The Ally, a heavy cropper of fine quality. Other second early immunes are Conquest, Mr. Breese, Border Queen, Snowball, and The Duchess.

The list of immune main crop varieties includes Abundance, and the numerous varieties of that type: Langworthy, What's Wanted, Golden Wonder, Rob Roy, The Lochar and Leinster Wonder, The Templar, several coloured rounds or ovals, such as Kerr's Pink Shamrock, White City, St. Malo Kidney and Majestic. A full list of these immune varieties is published in Food Production Leaflet No. 21, to be obtained free on application to the Board of Agriculture. Needless to say, those whose land is not in infected areas should refrain from planting immune varieties, except for seed-raising purposes, as it is important that all the available seed should be at the disposition of those whose land is infected with wart disease.

* November, 1917.

ORCHID NOTES AND GLEANINGS.

LAELIO CATTLEYA IRENSIS USK PRIORY VARIETY.

A FINE flower of this cross between Cattleya Iris (bicolor × Dowiana aurea) and Laelio-Cattleya bletchleyensis (C. Warscewiczii × L. tenebrosa) is sent us by R. Windsor Rickards, Esq., Usk Priory, Monmouthshire. It measures 5½ inches across, and the petals are 2 inches wide; the whole flower is compact in shape, and has a peculiar glow in the colour of the lip. The sepals and petals are light yellow with a slight veining of rose on the outer halves. The lip, which discloses C. bicolor in its short side lobes and pronounced median isthmus, and C. Warscewiczii in its expanded front lobe, is bright crimson, changing to light purple towards the crimped margin of the front lobe; the side lobes bear yellow lines from base to margin. The very stout column is white, tinged with violet on the upper surface. The flower resembles a very fine Cattleya Aclula in its general aspect, but Laelia tenebrosa gives depth of colour to the lip.

LAELIO CATTLEYA EUPHENO

MR. F. C. PUDDLE, gardener to W. H St. Quintin, Esq., Scampston Hall, Rillington, Yorkshire, sends a flower of a new hybrid between L.-C. Prince Leopold (C. chocoensis × L. cinnabarina) and Cattleya Dowiana aurea, which makes another useful addition to the hybrids with various shades of yellow and red. The flower, which is 6 inches across, has sepals and petals of orange colour, with a copper tint; the lip, with the side lobes well advanced before the column and recurved at the tips, is distinctly narrowed in the middle and only moderately expanded in the front lobe; the colour is blood red, with yellow lines from the base to the centre, where they merge in a yellow tint, running into the deep-red, front lobe.

THE WINTER ASPECT OF THE BUDS OF PLUMS.

THE systematic pomologist is always on the look out for some simple character which will be of use in diagnosing varieties. Such a character must obviously be constant and distinct, and if possible one that is available the whole year. In Plums the presence or absence of down on the stems is a useful guide, but a close examination shows that even this is not quite so constant as might be wished. Many of the varieties with "smooth" shoots, according to the pomologists, will be found to be slightly downy in parts, especially just above the axillary buds, and a minute examination will reveal a series which pass from the smooth to the downy in a graded order. The study of tree characters has never been given in this country the attention it deserves, and it is therefore to French authors we turn in a search for a character which will be more constant than downiness and one equally available during the winter. This will be found in the bud and its support. As a "telescoped" and undeveloped shoot the bud should not have had so many opportunities to vary as have such structures as the leaf and flower. This is quite borne out by the facts, so that we may say that the bud in winter state is the most constant character of any on the tree. It might be expected that all Plums of a similar character would show resemblances also in the buds, but this is not so. If we take the so-called Gages (see fig. 12), it will be seen that they differ among themselves in a remarkable manner. The prominent "support," which is the remains of the tissue carrying the vascular bundles to the leaf, is a character usually associated with this class, but it is by no means always sufficient to assist identification. In such varieties as Golden Esperen and Reine Claude de Bavay it is not more marked than in the ordinary Plums. In Coe's Golden Drop, Late Transparent Gage and Angelina Burdett it is very marked. The size of the buds shows a considerable difference, being very small in the Green Gage and Dennistoun's Superb, and large in Late Transparent and Oullin's Gage. The shape is perhaps the most striking feature. The short, rounded, conical forms, as in Count Althann's and Angelina Burdett, are usually associated with a neatly wrapped appearance that is, the bud scales are closely applied to each other. In other forms, as Early Transparent Gage and Oullin's, they are untidly wrapped, as the figure of the former well shows. The curved form of Golden Transparent is very characteristic and is not found, so far as I know, in other varieties. The direction taken by the bud, if closely applied to the wood or leaning away from it, is a very constant character, and varies only in that the lower buds on the shoot exaggerate this tendency a little. Coe's Golden Drop is a good example, while Late Transparent Gage shows the opposite extreme. The buds may also be downy or smooth, or in some cases the scales are edged with hair. Other points, such as the shape of the leaf scar, and the ridges left by the vascular bundles, will be noticed. Turning to other classes of Plums, the small conical bud of Pond's Seedling and the loosely wrapped and oval Belle de Louvain could not be confused in the winter state.

In the Damsons, too, the differences are equally marked: the round, downy bud of Farleigh Damson leaning away from the wood could not be confused with the smooth buds of Bradley's King and Prune Damson, while another downy bud, Frogmore Damson, would be readily picked out by its large size, vertical position and its prominent support.

Space will not permit the presentation of drawings of many types, but those shown will establish the fact that these bud characters are of some considerable utility for diagnostic purposes.—*E. A. Bunyard.*

THE EFFECT OF ONE GROWING PLANT ON ANOTHER.

FROM time immemorial gardeners have been convinced that certain plants injure others, and in many cases it is truly believed that the harmful effect persists in the soil for months, if not years. Thus many good gardeners are as convinced of the reality of "Onion sickness" of soil as they are of the reality of the Onion itself. This body of opinion has gradually crystallised and has led to the view that plants excrete something from their roots which is poisonous to other plants of the same kind, though not necessarily to plants of a different kind.

There are fashions in science as in other walks of life, and for a long period it was customary to regard the plant as being completely analogous to the animal. On this view it was only natural to expect a poisonous excretion, and consequently there was full harmony between the man of science and the practical man.

In more recent years, however, a good deal of doubt has been thrown on the idea of a poisonous excretion, and it has been shown that considerable difficulties arise in accepting this view. In a good grass field, for example, the plants are as crowded as they can be, and yet they show no signs of "sickness" or of being poisoned. If the soil is poor, they may, of course, go hungry, but that can be remedied by the addition of suitable fertilisers; there is nothing in the appearance of the plants to suggest that any other factor is concerned.

On the other hand, Dr. Whitney, the chief of the Bureau of Soils of the United States Department of Agriculture, published some years ago the view that plants do excrete a toxic substance, which, however, may be precipitated or otherwise thrown out of action by fertilisers. The fact, therefore, that fertilisers improve plant growth is not taken solely to show that they provide plant food, it is supposed that they also have this, and perhaps other effects as well.

This view was seriously contested both in England and in the United States, but, like other controversies carried on in a friendly spirit, it led to a great clarification of ideas, and to a considerable amount of work which has proved very helpful, and has resulted in a considerable advance of knowledge.

In the main, the British investigators have taken the view that there is no evidence of a persistent toxic excretion. This seems to be indicated by the Rothamsted experiments. At the present time the famous Broadbalk field is carrying its 75th successive crop of Wheat, and the plants look remarkably well, fully as good as any on the farm, and better than a good deal of Wheat in the district. The crop of Mangolds that has just been pulled is the 42nd in succession, and it as well above the average, and indeed has not often been exceeded during the whole period. Similarly, Barley has been grown for 57 years in succession, again without any sign of suffering. Leguminous crops, however, cannot be grown in this way, and after a short period they fail; so far as experimental evidence goes they are the only crops that will not grow year after year on the same land. There are observations to the effect that other crops fail also; it is said that Foxglove will make magnificent growth on the soil of a freshly cleared wood (provided the soil is suitable; *e.g.*, the clay patches on the Downs), for one year, but not afterwards; it is also said that Flax and Onions may fail if grown too often on the same land. But these are simply observations which, even if correct, might have some other explanation; no direct experimental evidence is forthcoming.

The view that plants excrete poisonous substances has been revived by the experiments of Mr. Spencer Pickering recently described in the *Gardeners' Chronicle*. Plants were found to suffer considerable diminution in growth if they received water that had washed part of the roots of another growing plant. The effect seems to be quite general; the washings from the roots of growing Mustard checked the growth of Mustard; grass checked the growth of fruit trees, and so on. Further experiments established the highly interesting point that these washings lost their poisonous quality very quickly, so that they would not necessarily affect the soil after plant growth had ceased. Thus the experiments are quite consistent with the Rothamsted field experiments just described.

Another set of Rothamsted experiments, however, appears to be more difficult to reconcile with Mr. Pickering's results. Dr. Brenchley has for some time been growing Wheat alone, weeds

FIG. 12.—WINTER BUDS OF PLUMS.

1, Golden Esperen Gage. 2, Coe's Golden Drop. 3, Late Transparent Gage. 4, Angelina Burdett. 5, Green Gage. 6, Dennistoun's Superb. 7, Oullin's Golden Gage. 8, Early Transparent Gage. 9, Golden Transparent Gage.

alone, and also Wheat mingled with weeds, and has obtained some highly interesting results.* When Poppy, Black Bent or Spurry were grown with Wheat they made less growth than when grown alone; the Wheat, on the other hand, made more growth per individual plant. This does not mean, of course, that Wheat should always be grown with weeds; the plant would have done better had no weed been present. Indeed, other plants grown without weeds did do better, but it suffered less from the presence of these weeds than it would have done from an equal number of Wheat plants. In these experiments Spurry proved more harmful than the others, its straggling habit smothering the young Wheat, giving it a bad check from which it never properly recovered. Charlock and Wheat settled down to some sort of equilibrium, neither gaining the mastery over the other.

So far as could be seen, however, the effect was solely one of competition for food, and it made no difference to the individual Wheat plant whatever its competitor was another Wheat plant or a plant of some wholly different order. The phenomena could all be explained

* *New Phytologist*, 1917, XVI, 53-76.

by supposing that the number of plants the soil could carry depended on the amount of plant food present in the soil and the amount of space available for growth; if the food and space are to be shared by many plants each individual will get a smaller share and will therefore make less growth than if there are fewer plants to participate.

At first sight this seems difficult to reconcile with Mr. Pickering's experiments, which would lead us to expect that a large number of plants would suffer not only from starvation but also from mutual poisoning, and therefore that there would be less growth not only individually but also collectively than when a smaller number is grown.

A way out of the apparent discrepancy may, however, be found. In another of Mr. Pickering's experiments plants grown in pots divided up into compartments so that each individual root was kept distinct from its neighbour made no better growth than plants grown in undivided pots where the roots of the different plants mingled freely. Thus the toxin produced by each individual plant does it as much harm as the toxin produced by its neighbour. Further, Mr. Pickering also found, working in open soil, that the total growth was the same whatever the number of plants (within certain limits as to distances apart), or, in other words, the weights of the plants were inversely proportioned to the bulk of soil available.

This is in full agreement with Dr. Brenchley's results, and it can be explained perfectly well without assuming the existence of a toxin, requiring only the recognition of the fact that the full crop-bearing capacity of the soil has been reached. If, with Mr. Pickering, we suppose a toxin to be present, we must further suppose that it is at least as harmful to the plant itself as to any other. This further assumption involves some possibilities which would lead to an interesting discussion, but it is safer and more profitable to await the further experiments which we may be sure the subject will call forth. *E. J. Russell*

TREES AND SHRUBS.

THE TURKEY OAK AS A PLANTATION TREE.

On p. 3, Mr. T. W. Bolas describes the Turkey Oak correctly when he says that it is very rapid in growth, and produces clean boles when the side branches are kept limited or within due proportion. Next to the common Oak (Quercus robur pedunculata) it is the most widely distributed in Britain, so far as my observations go. The species is relatively plentiful from the South of England to within three miles of the Moray Firth, and probably thrives further north. On the seashore its growth is limited, like that of all other forest trees, by the fierce gales from the sea in summer, when growth is being made. Nine miles from the coast, in river valleys, it forms quite as large a tree as the common Oak, and in private parks is preferred for its beauty, being of a dark green and amply supplied with branches. By the side of green lanes and ancient bridle paths in the South of England it forms stately trees 60 to 70 feet high, handsome and umbrageous, and there its seedlings may be seen of various heights, when not cut down. There are many fine trees in Surrey, and I have never seen the top in a decaying condition, such as is seen in hundreds of dilapidated old trees of the native species. Just how old the large Turkey Oaks may be it is difficult to say, but judging from their size I should say anything from 100 to 150 years; the species was introduced in 1735. Many of those to which I refer are growing on London clay, but where well drained the tree grows better and taller than I have stated. *J. F.*

THE TURKEY OAK AT MONREITH.

I am not aware of any reason for sharing the doubt expressed by Mr. Bolas (p. 3) as to the reasonable longevity of this tree. I happen to know the exact age of that one whereof I gave the dimensions on page 218, Vol. LXII. It stood beside a Beech, evidently of the same age, planted by my grandfather on his return in March, 1809, from the Coruña campaign, where he lost an arm, and neither tree shows any symptom of decay. *Herbert Maxwell, Monreith.*

LETTERS FROM SOLDIER-GARDENERS.

HORTICULTURAL DUG-OUTS.

I was pleased to read Mr. Peters' remarks on this subject on p. 222 of the issue for December 1 last. He gives his long experience as a proof of the correctness of my suggestions regarding the use of a dug-out for forcing. He has not been so successful with root and fruit storage. It is possible, as he will doubtless agree, that the conditions for successful storage could be arranged. I seem to harbour a belief that it could. Meanwhile, however, I bow to his experience. Mine, as I said before, are merely suggestions, but only experiment and experience can prove their value.

My other critic, *S. A.*, has, I think, misunderstood me. Perhaps that is through my careless writing and wording. I have not the advantage of having a copy of my article, and life out here is not conducive to the super-development of memory. Perhaps he has made the mistake of thinking that the curvilinear roofed iron dwellings I spoke of, I believe, as "French dug-outs," are really dug-outs. As a matter of fact, they are often built on the level, and are then barricaded with sandbags. In such conditions they can be completely dry and very warm; the ventilation and light are by no means ideal, but they could be made so but for a state of war. In my fourteen years' experience of hothy life in ten different counties I have seen good, bad, and indifferent hothies, and this I know, that if all had been as comfortable and as healthy as these iron buildings could easily be made in normal times, I think very few young men would have found it possible to complain.

I have not advocated—I do not advocate the erection of any form of dwelling which is insanitary in its full sense, but let *S. A.* remember that in normal times a "French dug-out" or a wooden hut may be made ideally sanitary. Don't mistake it; building material after the war will be dear, labour will be dear, and capital will be for a time timorously outlayed. These huts and other temporary buildings, being of no further use for Army purposes, will probably be cheap. I have yet to learn that brick or stone are essential to health or to comfort, though it probably may seem so to many rural and urban district councils.

Mistake me not, *S. A.* I have no intention after the war of digging myself in, even though I am an enthusiastic Sweet Pea grower and an advocate of deep tillage. I always contrive to keep my head above ground level. Soon after my return, I hope to "buy me a house," and it is not going to be a French dug-out nor a wooden hut, but some form of these structures is going to be in the vicinity to be used as a "sanctum sanctorum" where I can reply to my critics and welcome my friends, and I hope the two will be synonymous.

If, however, it happens that I am engaged in work which demands the comfortable housing of men, I shall continue to ensure their best comfort at a minimum of expense. Is that retrogressive? It is not my idea of retrogression. I must give *S. A.* the credit of misunderstanding me or myself the discredit of not explaining myself sufficiently well. *William F. Bowles, B.E.F.*

The Week's Work.

THE KITCHEN GARDEN.

By F. Jordan, Gardener to Lieut.-Col. Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Onions.—Seeds of Ailsa Craig, Premier, and Cranston's Excelsior Onions should be sown at about this date under glass in a temperature of 55° to 60°, to obtain large bulbs. To produce Onions for exhibition purposes, rich, deeply trenched ground is necessary, but whether the bulbs are intended for exhibiting or for home use, the utmost attention should be given to this important crop, owing to the restrictions placed on the importation of this vegetable. For spring sowing, James' Long Keeping, Veitch's Main Crop, and Brown Globe are all good varieties, and much may be done to accelerate the crop by raising these varieties under glass at the beginning of next month in cold districts, and especially where mildew or the Onion fly is troublesome, and planting them out-of-doors in April.

Cucumbers.—Make a sowing of Cucumber seed at once in 3-inch pots, plunging the latter in a bottom heat of 75° to 80°. When the plants have made three leaves, transfer them carefully to 5-inch pots filled with a light compost consisting of loam, leaf-mould, and sand. Place a small stake in each pot to make the plants secure, and plunge the pots in fermenting material arranged in a light position near the roof-glass. Maintain a warm, moist, growing atmosphere, and let the night temperature be 65 to 70°, according to the weather. Water the roots carefully.

Salads.—Salads are getting scarce, but a daily supply of Mustard and Cress is easily obtained, and these plants furnish a salad that is always appreciated. Sow the seeds fairly thickly on fine soil, pressing them firmly into it. Water the soil and germinate the seeds in a moderate temperature, excluding light until the seedlings appear. Chicory may be forced gently in a Mushroom house. Endive may be blanched in any cool, dark place, or in the pits or frames in which the plants are grown.

Winter Crops.—Autumn-planted Cabbages have suffered in many places from excessive rains, which have checked growth considerably, and favoured the spread of slugs. At the first opportunity, when the weather is mild, loosen the soil about the plants of all winter crops.

Cold Frames.—Such plants as Cauliflowers, Lettuce, and Endive which are growing in cold frames require careful attention, keeping the soil stirred between the plants and the ground clear of weeds, to prevent damping. Admit air on all favourable occasions, increasing the amount gradually.

General Remarks.—Make sowings in pans or boxes, filled with fairly good soil, of Tomato Sunrise, Cauliflower Magnum Bonum, Brussels Sprout Dwarf Gem, Lettuce All the Year Round, Cabbage Sutton's Earliest, Leek The Lyon, and Broad Bean Green Windsor. The Broad Beans may be sown in 4-inch pots, to be planted out later. Seeds of this vegetable may also be sown in the open in favourable districts on warm borders. Every effort should be made to have plants in readiness to fill all available spaces as soon as the condition of the weather permits. All available labour should be concentrated on getting pits, frames and ground that will be needed ready in time for early planting. Sowings of the vegetables named should be regulated according to the date when young plants will be required in the spring.

THE HARDY FRUIT GARDEN

By Jas. Hudson, Head Gardener at Gunnersbury House, Acton, W.

Mulching Fruit Trees.—Mulching should consist of a light surface dressing with matured farmyard or stable manure. It should be broken somewhat finely and spread around the trees.

Excessive mulchings encourage lank growth. Mulching is more necessary for light soils than for heavy ones, and for well-drained soil than for low-lying or wet land. Fruit tree borders that are sloping or narrow need careful mulching.

TOP-DRESSING FRUIT TREES.—When adding new loam to the roots of the trees, first carefully remove the surface soil around the roots for a fair distance away from the stems, especially in the case of trees that have for some years borne heavy crops of fruit. This process also supplies an opportunity of giving the trees a little artificial manure in which there are good percentages of both phosphates and potash. In using such a manure, however, do not exceed the proportions recommended by the makers. Many estates can supply their own requirements of loam without any difficulty.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

EARLY PEACHES.—In most gardens the early Peach houses will be closed for forcing later than usual this year, and, however brief the respite, the trees will benefit greatly by the longer period of rest. The flower-buds on these early trees are swelling, but before the flowers open fumigate the houses to destroy green and black aphides. If the one fumigation is efficient, it should not be necessary to fumigate the house again until the fruits have set. Peach and Nectarine trees will only submit to gentle forcing, and until the flower buds show colour the temperature of the house should not exceed 45° at night, with a rise of 10° by day. During the flowering period maintain sufficient fire heat to keep the thermometer at 50° by night; during very cold weather a few degrees lower will cause no harm, but excessive fire heat will result in the trees casting their flowers. Admit air on all favourable occasions, and if the top ventilators are open about one inch at night until the flowers begin to fade, so much the better. Maintain a dry, buoyant atmosphere, to ensure the pollen being dry and readily disseminated. When the trees are in bloom, touch the flowers lightly at midday with a rabbit's tail tied to a cane. Pollinating the blooms in this way is essential in the case of early Peaches and Nectarines. Immediately the flowers are set, light syringings with tepid water twice daily, according to the weather conditions, will assist the embryo fruits to swell.

EARLY VINES.—In starting early vineries, a night temperature of 50° to 55° is sufficient, with a rise of 10° during the day before admitting air, but this is not necessary till the buds are on the move. Maintain a moist atmosphere to assist the vines to start into growth freely, syringing the houses twice daily, according to the weather, and always using tepid water. Pot vines which were started last month are advanced sufficiently for the shoots to be thinned, but this must be done with caution, or shoots containing the embryo inflorescences may be removed. If the pots are plunged in hot bed material the dung should be renewed before the heat gives out. Regulate the work of syringing and damping according to the weather, for an unduly moist atmosphere is not conducive to healthy foliage. Pinch the side shoots two leaves beyond the bunches, and allow the leading shoot to continue growing for the present. Examine the pots for water, and when moisture is necessary, afford sufficient to thoroughly wet the roots, using tepid water, and tepid liquid manure when the latter is used. Tie the lateral shoots by degrees to the trellis, or they may snap at the base. Maintain a night temperature of 65°, with a rise of 10° during the day before air is admitted.

CUCUMBERS.—To meet the demand for early Cucumbers, sow seeds at once singly in small pots, and plunge the pots in a bottom heat ranging from 75° to 80°. The plants may be repotted once, although this is not necessary if plenty of heat is available. Pines are no longer grown in these gardens, and we find the Pine-pits well adapted for growing Cucumbers. These pits have an excellent supply of hot water pipes, and there is no difficulty in maintaining a night temperature of 65°, with a rise of 15° by day. A hot bed of stable litter and leaves is placed on the stages, the mound of soil, composed of fairly loam, well decayed manure, and a little charcoal, being placed at equal distances along the bed. When the soil is warm, the plants are set out. A moist atmosphere is promoted by syringing the plants and their surroundings twice daily, and once only on dull days.

PLANTS UNDER GLASS.

By F. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

ROSES IN POTS.—Batches of Roses may now be safely introduced into a slightly heated temperature as required, selecting plants which have made fairly strong, well ripened wood. Before placing them indoors, see that the drainage of the pots is quite clear. Cut back all weak growth, and if necessary slightly cut back the flowering wood. Remove all useless wood from climbing varieties, and tie the flowering growths neatly to stakes. Forcing by the excessive use of artificial heat must not be attempted, as this will cause the flower stems to be weak, and of little use for decorative purposes. If forcing is necessary, make use of the sun's rays by closing the house in the middle of the day, but open the top ventilators a little during the night. When the flower buds begin to open, the roots must be watered with a concentrated fertiliser and soot water alternately. Roses require plenty of fresh air when the weather is favourable, but cold draughts must always be prevented, or mildew will attack the foliage. As a precaution against aphis, fumigate the house occasionally, and should mildew appear, dust the foliage with flowers of sulphur.

CYCLAMEN.—Seedling Cyclamens which were raised in the autumn will now be in need of a shift. They may either be potted into small pots, or pricked out into pans or boxes. There will be less likelihood of a check if the latter method is adopted. A light, sandy compost should be provided, and the pans must be efficiently drained. Keep these young plants growing slowly in a moist atmosphere near to the glass. A night temperature of about 50° will suit them, but the temperature may be allowed to rise 20° higher during the day by the judicious use of sun heat. The old plants which are flowering must be carefully watered, using stimulants of moderate strength until they are in full flower. To prolong their season of flowering, keep the atmosphere cool and dry, admitting plenty of air when outdoor conditions are suitable.

CLEANING PLANT HOUSES.—To keep plants in a healthy condition it is necessary that their surroundings be perfectly clean. Before the busy season arrives the glass and wood work inside and out should be thoroughly cleansed with soapy water. The materials on the stages, too, should receive attention. When arranging the plants again on the stages, see that they are not placed too closely together. Climbing plants may now receive the necessary pruning or thinning, and be again tied neatly to their supports. When this is done, remove an inch or two of the surface soil from the rooting area and replace with fresh materials.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

DENDROBIUM.—The flower buds of many Dendrobiums, including both species and hybrids, are showing, and the flowering season may be extended by removing some of the more forward plants from their resting quarters to a house having a slightly higher temperature. A careful selection is necessary, both in regard to variety and the condition of the plants. Only well rooted and thoroughly ripened specimens should be chosen, and preference should be given to hybrids of D. nobile and D. aureum. Having selected the plants, they should be given only sufficient water at the roots to keep the pseudo bulbs plump, for if moisture is too liberally applied, it will cause many of them to start rapidly into growth, and the flower buds will turn yellow and drop, or the plants will produce flowers of inferior quality. They should be first placed in a house where the temperature is a few degrees warmer than that in which they have rested, finally transferring them to the stove or warm division. Unless early flowers are especially desired, forcing should not be hurried, only sufficient warmth should be employed to cause growth to develop gradually. With this treatment the blooms will be larger and of greater substance than when much fire heat is employed. Keep a sharp look-out for slugs, or they will damage the flower buds as soon as the latter begin to develop. Traps of damp bran or Lettuce leaves should be placed about the stages near the plants, and the pests searched for at night time and in the early mornings. Plants of tall growing species, including D. moschatum, D. fimbriatum, D. clavatum, and D. dixanthum, should still be resting, and remain dormant for the next two months. D. Dalhousianum should be grown in the warmest house at all times, and should not be kept excessively dry at the roots during the resting season. Afford the plants sufficient water to keep the stems and leaves fresh and plump, for if these plants are kept too dry during their period of rest, the next season's growth will often be deficient in strength.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

SWEET PEAS.—Sweet Peas can, as a rule, be utilised in the furnishing of the flower garden proper, rather than, as in past times, taking up space in the vegetable quarters. There are many ways of utilising Sweet Peas. A row of a white sort is very pleasing, or we may have blue tones, or blue and yellow with Canary Creepers (Tropæolum canariensis) intermixed. Or pink, either all pink or associated with colours that go with pink, or, last of all, a mixture of Sweet Pea colours. It is many years since I employed Sweet Peas in the flower garden, and their employment was stopped solely because of high winds, which wrecked them when at their best. To have strong plants it is worth the labour to sow thickly in cutting boxes, the seedlings to be transferred singly into 4-inch pots, when large enough for the shift, growing them slowly in the cool, and pinching the tops to ensure several shoots from each. Only the stronger growing sorts should be chosen, such as Dobbie's Cream, King White, Edrom Beauty, and Edith Pearson. Sow at once, and cover the boxes with some mouse-proof material until the plants are safe from the attention of these animals.

SNOWDROPS.—I incline to the belief that the masses of common Snowdrops which we established here are constantly being renewed by seedlings, the older plants dying after a time. There are comparatively few clumps of one variety, and any noteworthy sort that attracts one's attention invariably disappears. It is therefore of importance to add new material to the surface to give seeds the best chance to germinate, while it increases the vigour of corms that have become established. Any very light soil passed through a fine meshed sieve and spread thinly and evenly over the ground occupied by the Snowdrops suffices, and, of course, there is no time to lose, the earlier forms being soon due above ground. Some years they appear with the New Year, but this is a late season. Strong growing species, such as Galanthus Imperati and G. pheatus, may instead of soil have a thin surfacing of rotted manure applied.

TRIMMING IVY. This is not the best time of year to trim Ivy, but I find that the work can be done now without the labour entailed causing any derangement of work in general. It is a great mistake to miss cutting Ivy annually, apart altogether from the unsightliness that follows neglect. But it is not important to cut close in, so long as the shoots that break away from the main body are cut, and those which grow beyond bounds at the sides of windows, doorways, and the tops of walls. Much saving of labour is effected by spreading canvas sheets to catch the clippings.

LAWNS.—A final clean up of lawns on which leaves, sticks, and other rubbish has accumulated recently may be made after a period of wet, when other work is at a standstill. Owing to the very open weather subsequent to the stoppage of grass-cutting in autumn, our lawns are very rough, and it will be necessary to put a heavy roller over them as soon as they are in condition to bear it.

EDITORIAL NOTICE.

Editors and Publisher. *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations. *The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 38.9.

The 1918 Potato Crop and State Purchase.

The announcement of the arrangements made by the Ministry of Food for the disposal of the 1918 Potato crop are opportune, for it indicates to all concerned that the Government is prepared to encourage the largest possible production of Potatos. This attitude is undoubtedly wise, for although the bulkiness of the Potato crop makes the task of transporting it extremely difficult, nevertheless it is the crop which of all others produces the largest amount of food per acre. Furthermore, there should be ample time between now and the lifting of the crop for the perfection of arrangements already being made whereby large quantities of Potatos may be dried and milled and rendered available for use in bread making. In order to encourage the growing of Potatos on the largest possible scale, the Food Controller has announced that he is prepared to enter into contracts with farmers for the delivery as and when required of approved varieties of main crop Potatos at the following prices (f.o.r. or f.o.b.): November 1 to January 31, England and Wales, £6; Scotland, £5 10s.; February 1 to March 31, £7 and £6 10s.; May 1, 1919, to end of season, £7 and £6 10s.

These terms will only apply to acreages in excess of the total acreage of the farm in 1914, and they will only be granted if the 1918 acreage under Potatos on a given farm is not less than that of 1917.

A further condition lays down that any conditions with respect to spraying, harvesting, or pitting enforced by the Board of Agriculture, must be duly followed out. Those who wish to grow on contract under these terms must apply for contract forms between February 1 and May 1, 1918, to the Director of Vegetable Supplies, 18, Upper Grosvenor Street, London, S.W. 1.

Having defined the means whereby it is hoped to maintain and increase the area under Potatos, the Food Controller proceeds to deal with the crop as a whole. As from November 1, 1918, he will take over all the crops except those grown on holdings containing less than one acre of Potatos and those grown for own consumption or for experimental purposes. The price at which the crop will be taken over will be regulated by the size and quality of the crop, but will not be less than the following scale (for f.o.r. or f.o.b. prices):—

November and December: England and Wales, £5; Scotland, £4 10s.

January and February: England and Wales, £5 10s.; Scotland, £5.

March and April: England and Wales, £6; Scotland, £5 10s.

May to end of season: England and Wales, £6 10s.; Scotland, £6.

Growers will have the right to retain any seed they may require for their own use.

It is not at present contemplated to take over or fix prices for the 1918 crop before November 1. Should, however, the food situation require the fixing of maximum prices, the prices will not be less than the following:—

July 1 to 15, £14.
July 16 to 23, £12.
July 24 to 31, £10.
August, £8.
September to October, £7.

The corresponding arrangements for the Irish crop will be announced later.

The object in discriminating between the Scotch crop and that grown in England and Wales is to discourage the consumption of Potatos grown in the neighbourhood of the principal consuming areas.

With the scheme before him the grower should be in a position to judge what part of his acreage he should devote to early and what part to late Potatos. In forming that judgment he will be guided by his estimate of demand, the suitability of his soil for early varieties, and his general cropping programme. Although each person must decide for himself, we for our part hold the view that on patriotic grounds, at all events, skilled growers should prepare to plant—provided their soil is reasonably early—a considerable breadth of second early varieties. For it is important in the coming year that there should be a large supply of Potatos and that the supply should begin to come in in large volume as early in the season as is possible.

The National Rose Society.

At the annual meeting of the National Rose Society held on Tuesday last at the Holborn Restaurant, the President, Mr. E. J. Holland, in moving the adoption of the report of the Council, stated that 210 new members had been added to the Society in the past year.

The usual spring and summer shows had not been held, but through the courtesy of the Royal Horticultural Society a special class for seedling Roses had been provided by the Society at one of the R.H.S. fortnightly meetings in July, and a modest and unpretending show, on a non-competitive basis, was held in the Drill Hall in the autumn. The publications issued by the Society during the year had consisted of *The Rose Annual* and a revised list of Roses, with instructions in pruning. The Council had decided to form a library for the use of members, towards which a few books had already been purchased.

The programme of the Society for 1918, said Mr. Holland, had been carefully and anxiously considered by the members of the Council, and it had decided to arrange a series of shows of modest dimensions, so as to continue the work in a quiet way. There would be a spring show at the Drill Hall on May 7, a show at Regent's Park on July 1 in aid of the Red Cross Funds, a special meeting on July 16 for the display of seedlings, and an autumn show at the Drill Hall on September 10.

He invited discussion on this programme. The Council had ascertained that in three cases the shows would involve no preparation, while in the case of the summer show the proceeds would go towards an excellent object. Mr. H. R. Darlington seconded the motion, observing that he had at first been against holding any shows in the current year, but finding that the shows at the Drill Hall would involve no expense or preparation, while in the case of the summer show use could be made of accommodation provided for other purposes, he felt unable to press the objection. Mr. Frank Cant questioned the policy of holding the proposed shows, while Mr. Pemberton, who was supported by Mr. Burnside, moved an amendment asking the Council to reconsider its proposal for the summer show and to hold it in a hall, instead of at Regent's Park. The recommendation of the Council, however, was supported by Mr. Burgess and Mr. George Paul. The amendment on being put to the meeting was lost by a large majority, and the report of the Council adopted.

The treasurer of the Society, Mr. Preston Hillary, made a statement as to the finances, and moved a resolution, which was carried unanimously, suspending the operation of certain rules, in order to enable the Society to make a contribution to the Red Cross funds. He mentioned that, after purchasing £1,000 war loan, the Society had a balance at the end of the year of £321.

Mr. H. R. Darlington then stated that the Council had decided to award two Dean Hole Medals, one to Mr. E. B. Lindsell and the other to their president, Mr. E. J. Holland. The Dean Hole Medal was the highest honour the Society had it in its power to confer, and it was awarded for good work done in connection with the Rose. During the twenty-one years from 1890 to 1911 Mr. Lindsell had won the Amateur Cham-

pionship Cup no fewer than nineteen times and had carried off the Jubilee Challenge Trophy given at the Provincial Show on twelve occasions. These were feats that were unique in the annals of the Society. Contest in various forms had an ennobling influence on those who engaged in it, but the peaceful contests of their Society involved long years of preparation and many "days of fresh air in the wind and the sun," that were no less delightful in the memory than pleasant and healthful in their pursuit. The medals he had the honour of presenting, on behalf of the Society, would remind them of those hours of recreation, and also of the great Dean, first president of their Society, and the Homeric conflicts he waged with Mr. Newdegate, of Asbury, before the Society was formed in the early seventies. Mr. Holland had not only won a high place as an exhibitor, but had devoted much time and work to the service of the Society. The first recipient of the Dean Hole Medal was Mr. Pemberton, one of Mr. Lindsell's most serious opponents, and one of the very few who had ever wrested from him the Amateur Championship; it was very satisfactory to see him amongst them on that occasion.

NATIONAL DAHLIA SOCIETY.—The annual general meeting of the members of the National Dahlia Society will be held on Monday, the 21st inst., at 35, Wellington Street, Covent Garden, the offices of the British Wholesale Florists' Federation.

SOCIÉTÉ NATIONALE D'HORTICULTURE DE FRANCE.—The administrative council of the Société Nationale d'Horticulture de France, finding it impossible this year to arrange for the usual annual elections, has decided to extend for one year its own powers, and the powers of the various administrative committees. The committees will be entitled to co-opt additional members, should such a course be rendered necessary by the resignation of existing members or by any similar cause.

THE SELBORNE SOCIETY.—Steps are being taken to incorporate the Selborne Society, and to widen its objects, so that it may not be hampered in its efforts to bring home to the public, more especially through its lectures, the great value of science to the community. Existing members will be registered upon demand without entrance fee or re-election, and diplomas will be granted to lecturers, guides and teachers who satisfy the Society that they are qualified to carry on its work. Full particulars can be obtained from 55, Avenue Chambers, W.C. 1.

BREAKING-UP GRASS LAND.—Under the above heading, the *Daily Telegraph* reports that, writing to SIR JOHN GRANT LAWSON, the President of the Board of Agriculture (Mr. PROTHERO) says: "Where the tenant's agreement or lease either prohibits him from breaking up grass land or makes him liable for a money payment if he does so, an order under the regulations enables him to break up the land without becoming liable to pay any penalty or to bear the cost of putting down to grass again. If the owner suffers any direct or substantial loss, he is entitled to apply for compensation to the Defence of the Realm (Losses) Commission."

UNIVERSITY LECTURES.—In connection with the work of the Imperial Studies Committee of the University of London, a course of ten public lectures on "Some Biological Problems of To-day" has been arranged, and will be held at University College on Mondays, at 4 p.m., beginning January 21. The following are particulars with regard to the first five lectures:—(1) "The Problem of Food," by Professor W. M. BAYLISS; (2) "War Bread and Its Constituents," by Professor F. G. HOPKINS; (3) "Accessory Food Factors (Vitamines) in War Time Diets," by Miss E. MARGARET HEMP; (4) "Alcoholic and other Beverages," by Professor A. R. CUSHNY; (5) "The Possibilities of Increased Crop Production," by Dr. E. J. RUSSELL, F.R.S. The lectures are open to the public without fee or ticket.

FIG. 15.—DAHLIA CACTUS VAR. GENIUS BRYNDIR VAR.

(See "Words of Merit," by R.H.S. Orchid Committee, p. 29.)

COMMERCIAL FERTILISERS FOR ROSES.*—The conclusions reached by Mr MUNCIE as the result of a long series of tests are that the nitrogen required by Roses is best supplied either by farmyard manure or by green manuring; that acid phosphate should be used generously, either at the rate of 4-8 tons to the acre in the nursery or in compost with soil at the rate of 10-30 lbs. per 100 cubic feet. By the use of acid phosphate in the quantity prescribed, the author obtained an increase of blossom of 4,100 flowers from 1,000 plants, whence it follows that the cost of the fertiliser is insignificant in comparison with the increased value of the crop. Rose growers who have not hitherto used acid phosphate should take note of these striking results of application in more propitious times.

CHINESE CABBAGE.—According to a note in *New Plant Introductions*,† the Pe-tsai or Chinese Cabbage (Brassica pekinensis), trials of which have been made in this country, should be planted in autumn. If sown in spring it bolts. It is recommended to sow in July and to harvest after the first frost. If the green leaf tips are cut off before cooking it will be freed from its penetrating Cabbage odour. A variety (No. 24,052A in *Inventory of Seeds and Plants Imported July 1-September 30, 1917*) is described as being particularly fine, very white, of mild and sweet flavour, and weighing up to 10 lbs.

PUBLICATIONS RECEIVED.—***The Mistletoe: Its Life-History and Associations with Primitive Religion, Folklore, and Superstitions.*** By Sir Daniel Morris, K.C.M.G. Reprinted from the *Bournemouth Guardian*.—***The Land.*** By John Galsworthy. (London: George Allen & Unwin, Ltd.) Price 6d. net.

ON INCREASED FOOD PRODUCTION.

EARLY SPRING-SOWN BRASSICAS.

THE severe winter weather which prevailed last year destroyed many of the spring Cabbage plants in this neighbourhood, and in consequence there was a great shortage, and prices for a time ruled high. Cabbages that were planted direct in their permanent quarters and in sheltered sites came through fairly well, but those in the seed-beds were ruined. To augment the supply of plants I adopted a plan which was an entire success and which may also be followed in the case of early Cauliflowers and Brussels Sprouts.

A deep cold pit which had been previously filled with freshly fallen leaves and prepared for early Potatos was planted about the end of January, at the same time drawing two shallow drills between each line of Potatos, into which were thinly sown seeds of the above-mentioned Brassicas. The seed germinated splendidly, and the conditions suited the young plants admirably. In due course, as the rough leaves were formed, the seedlings were pricked out in skeleton frames, and gradually hardened off, making fine plants for setting out in April. The method, which I intend to repeat, has much to recommend it, and it is a great saving of labour, there being no boxes to clean, crock, and prepare, no watering, labour entailed in shifting saved, and lastly, the plants lifting much better and more easily, less care being needed than when the roots are closely confined in boxes. They were all ready to shift before the Potatos made much growth, and the loosening of the soil benefited the latter crop *E. Beckett, Fota Gardens, Queenstown*

PARCHED PEASE.

HAS anyone a recipe of the mode of preparing these? I take it that the treatment is somewhat that of baked Beans, for which I have no satisfactory procedure. Certainly if parched Peas are as good as the baked Beans which one gets in U.S.A., they ought to be worth resuscitating from antique cookery books. *H. E. D.*

DRIED PEAS.

THE Mangetout Dwarf Breton Pea (sans parchemin hâtif nain breton) is excellent in its dried ripe state. I have lately tried it as pease pudding, in croquettes made thereof, and also whole in stew and soup. It is of excellent flavour and melting consistence; its thin skin or pericarp is not obtrusive, in fact, it disappears in the cooking. The strain I have had for several years is a good 3 feet in height, and should not be sown or planted too thickly, as each plant makes a bush of growth. The flowers are white, and the production of pods very free over a considerable period. The seeds are rather small, yellow, and round, but they swell well, and the great productivity discounts a loss in size. It is rather liable to mildew, for which a spraying or two with 1 per cent. lime-sulphur seems to do good, as with other Peas. For mangetout purposes only pods with thin, papery shucks should be kept for sowing; with about four years' selection all hard pods seem now to have been eliminated. I think that the variety is worth considerable cultivation. After all, what is a better breakfast than some of these pods tossed in the fat of the fried bacon—bacon and mangetout Peas? *H. E. Durham.*

DEGENERATION OF POTATOS

THE reasons advanced by Mr. George M. Taylor for the degeneration of Potatos are fairly numerous, plausible, and in certain cases generally accepted by those who have studied the matter. Doubtless, many other causes at work remain to be discovered, so that much has yet to be accomplished by the pathologist. Exceptions, however, can be cited that run contrary to any thesis that one may advance to support an opinion. For instance, I know of a case where a gardener, and his father before him, grew Ashleaf Kidney on the same border consecutively for fifty-one years, and may still be doing so. The old Scotch Champion was in the height of its vigour in the seventies of last century, and is still grown. Deep eyed Potatos have not been driven out of commerce, for Great Scot, Sir Douglas Haig, and Southampton Wonder, the modern representatives of Champion, have deep eyes, and are certainly vigorous. On the contrary, Schoolmaster has not very deeply sunken eyes; though it has been in commerce since 1876, is immune to wart disease, and is still cultivated to a considerable extent. Starch is the last to be attacked by wart disease, and that evidently applies to some other fungi. During the past season I examined two varieties of Potatos that seemed to be attacked by leaf curl, though the haulm showed no signs of disease till attacked by late blight (Phytophthora). Under the microscope I could find no trace of mycelium in the blackened portions of the tubers, and concluded that the disease was bacteriosis (Bacillus solanacearum). The tissues were reduced to fragments, but the starch was abundant, pearly white, with the hilum and lamination of the grains still distinctly visible. It is my opinion also that vegetative methods of propagation need not be the cause of degeneration. Besides the cases I have mentioned, others could be cited of longevity under cultivation and in a wild state. Some plants have no other method of increase, and many of them have existed for centuries. The improvements effected by man amongst Potatos are not in all cases conducive to longevity, and high-grade, floury, white Wheat may be cited as another instance, where improvements have rendered such varieties unable to withstand severe winters and uncongenial soil and summers. Again, Potatos are often grown commercially on soils that are not the most suitable. Seed tubers of the varieties King Edward VII., Queen Mary, and Evergood realise 10s. more per ton, wholesale, when grown on the best Lincolnshire silt land, than the same varieties when grown in dark soils. *J. F.*

PEAS.

RICH soil, deep cultivation, and a liberal supply of manure are needed to grow good Peas. The plant needs plenty of moisture, and during dry periods should receive a liberal supply of clear, soft water at regular intervals. Weak liquid manure may also be given with advantage when the pods are swelling. A mulching of farm-yard manure will do much to retain the moisture in the soil, but this should be applied before the plants show the slightest signs of distress from drought, or very little advantage will be gained by it. As soon as the plants have been carefully staked, the ground between the rows should be lightly broken and the mulching applied, placing some of the material close to the stems.

The first sowing may be made in the open as early in January as the state of the soil permits, and varieties with a hardy constitution should be chosen for sowing. The situation should be sheltered from cold winds. Make the seed drills 4 inches deep and the same in width, running them from north to south in order that the plants may receive all the light possible. For the earliest sowing the seeds should be sown thickly, and covered with 2 inches of the finest soil from the drills. The remaining soil may be placed on the windward side as a shield from cold east winds.

In order to maintain an unbroken supply of pods from the beginning of June until the plants are destroyed by frost in the autumn, it is necessary to sow regularly as soon as the young plants from the previous sowing are through the surface. Certain varieties of Peas take much longer to mature their pods than others, and this fact should be considered at the time of sowing. For instance, Gradus, Discovery, and Alderman sown at the same time would form a very good succession, but these varieties should not be sown in the open before the end of March, or many of the seeds may perish. Round-seeded, hardy sorts only should be sown in the open for the first crop, and for this purpose The Pilot is the best variety.

If seeds are sown in pots or boxes under glass at the end of January and gradually prepared for planting at the end of March or early in April, an advantage of a few days may be gained, especially if the spring is unfavourable for plants in the open. For this purpose The Pilot may also be sown with Gradus, Early Giant, and Bountiful. If early dwarf kinds are preferred, Little Marvel, Langley Gem, and The Sherwood are good in every respect. Second early and main crop Peas should be sown thinly in an open position, the distance between the rows being regulated by the height of the varieties. As the season advances the seed drills may be taken out a little deeper than is usual for early crops, so that after the seeds are covered with 2 inches of soil there may still remain a sufficient space for earthing up the plants without forming a ridge, which is sometimes the means of casting rain-water away from the roots at a time when moisture is needed. Second early varieties may include Duke of Albany, Alderman, Discovery, Matchless Marrow, and Quite Content, which for large, well-filled pods has few equals.

Main-crop Peas should be sown thinly on rich, deeply cultivated soil in an open situation. If the soil is dry at the time of sowing, make the drills a day previous to sowing, and water it thoroughly, using soft water. The seeds should be sown the following morning. Main-crop Peas are frequently affected by mildew, but early mulching will do much to prevent this trouble. Main-crop varieties may include Royal Salute, 4 feet; Eureka, 3 feet; Perfection, 3½ feet; and selected Ne Plus Ultra, 6 feet. The last sowing should be made in June; at Windsor the last sowing is made as near the middle of that month as possible. It has been found that late varieties sown from the beginning to the middle of June give much better results than early sorts sown in sheltered borders in July. It is necessary for these late-sown Peas to be given strong sticks, as winds are often high and destructive in October. For this sowing, Gladstone, 4 feet; Rearguard, 4½ feet; Distinction, 4 feet, and Autocrat, 4 feet, will give pods throughout September and October, until the plants are cut down by frost. Peas are often attacked by birds during both spring and autumn, and to prevent this it is sometimes necessary to net the rows. *J. Dunn, Frogmore Gardens, Windsor.*

COMPETITION FOR ALLOTMENT HOLDERS.

THE Sulphate of Ammonia Association offers prizes to allotment holders in England and Wales for the largest amount of food produced on plots of a given area. In awarding the prizes the judges will consider economical methods of cultivation and the husbandlike manner in which the plot has been managed. The prizes will consist of War Loan Bonds of the value of £25, £20, £15, £10, and £5 respectively. Particulars of the competition may be obtained from the Northern offices of the Association, Gas Offices, Crowlands, Southport.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CUPRESSUS FORMOSENSIS (see p. 19).—I think Mr. Vicary Gibbs is right in attributing his failure with this Cypress to soil rather than temperature. We have only one plant here, given me as a small seedling by Mr. Elwes. It was kept in a cold frame through the winter of 1915-16, planted out in spring when 12 inches high, came through the severe winter of 1916-17 uninjured without any protection, and this year it has taken no notice of 23° of frost, which we had on the night of January 7-8. I think this may be taken as proof that the species is thoroughly hardy on suitable soil. It is true that here we have a mild western climate; but Dawyck, where this Cypress has proved hardy, is in a very cold district, the winter there being far more severe than in Hertfordshire. *Herbert Maxwell, Monreith.*

LIME WASHING.—The need for lime washing is near at hand, so attention may be called to a practice advocated in some recent French books of adding one part of clay to two of lime (by volume) as a means of caising the lime to adhere. I give the suggestion for what it may be worth, as I have not yet tried it. *H. E. D.*

STORING APPLES (see pp. 8, 19).—I am sorry that your correspondent *Puzzled* is perplexed as to the advice given by Mr. Hudson and myself in the issue for January 12 on the storing of Apples. Mr. Hudson is a foremost authority on all matters appertaining to horticulture, and even in our two articles I think I can claim there is little or no divergence of opinion. Last autumn we harvested the largest crop of Apples ever obtained at Aldenham, and we carried out the method I recorded in my note to the full. Never have we had better fruit, and certainly never so few decayed in store. Though we have a large fruit-room, it was not nearly large enough to hold our crop of Apples, even when every possible inch of space was occupied. The space that would have been required if we had acted on the principle so often advocated of laying the fruits out singly would have been beyond us. What I particularly wished to emphasise was the fact that the majority of inexperienced growers err on the side of keeping store-houses much too warm and dry, and as an example to illustrate that this was not necessary, I mentioned the case of the fallen Apple, which, receiving protection from frost under fallen leaves, keeps so well, being doubtless assisted in this by the moisture from the damp earth. This was not, as *Puzzled* suggests, a proof of "the necessity of their being perfectly sound," or, as he may mean, the advisability of piling the fruit. At this season of the year the fruits are becoming considerably fewer, and the later varieties can be thinned out to occupy more room, but this does not alter my opinion that piling does no harm, and most likely assists the keeping of Apples. In confirmation of my previous remarks I shall be pleased to show *Puzzled*, or anyone else interested, the results of fruit stored in the way I recommended. *Edwin Beckett.*

Your correspondent, *Puzzled*, is troubled in mind at what he conceives to be a conflict of opinion between two gardening experts, Messrs. Hudson and Beckett. He need not be; Mr. Hudson, speaking generally of storing fruits, says that where possible they should not be allowed to touch one another, and very sound advice, too, having regard to the readiness with which damaged or diseased fruit will infect sound. Nevertheless, I cannot imagine a practical man proposing to apply this rule to a comparatively hard, cheap, abundantly produced fruit like Apples. If it had been so applied at Aldenham during the last two years, instead of a modest fruit room, one built on the scale of a colossal ballroom would have been requisite to hold the output of the orchard. I may remark that if there were such a conflict of testimony as *Puzzled* represents, which there is not, affirmative evidence is much stronger than negative. If one of two men, of equal character and capacity, were to warn me against doing a thing, and the other were to tell me that he had himself done it for years without disadvantage, I should not hesitate to make the experiment. I am at a loss to understand why *Puzzled* should quote some further excellent advice of Mr. Hudson's as to the careful handling of fruit and separate taking up of each. There is nothing in Mr. Beckett's writing in conflict with this, and none is likely to be found in that of any sensible man. *Vicary Gibbs.*

—— In reference to the controversy as to methods of storing Apples, my experience indicates that the fruit keeps best when not spread out thinly, as it is less likely to shrivel. Fortunately this is the case, as the space in a frost-proof fruit-room is much too precious to allow of laying out the Apples so that they do not touch each other, and such a method would be useless to a market grower who needs to store large quantities. My plan, which has proved quite satisfactory for years past, when the Apples for storing have been properly selected for soundness, is to place about 20 lbs. in a handled tray 2 feet by 1 foot, really a Potato sprouting box, and pile up full trays to the ceiling, one tray being empty and turned upside down at the bottom of each tier, to avoid too much dampness from the earthen floor, which has been found a cause of rotting when the bottom tray has been filled. The filled trays are placed in tiers, 14 in a tier. The Apples are two deep in a tray, and packed closely. The space available inside rafters in my fruit-room is 18 feet 9 inches by 14 feet 6 inches, with a height of 10 feet 4 inches. Allowing two passage ways along the length of the room and one across the top, 1,092 trays can be stored, containing 500 to 550 bushels according to the proportions of heavy and light varieties. As there is a space between the top layer of Apples and the handle in each tray big enough to get the arm in, the fruit can be inspected at any time by walking down a passage way. At the present time we are getting a little over a bushel of 10 lbs. of sound Bramleys out of two trays, and from a lot of 21 bushels recently sold, only twelve Apples had to be taken out as unsound. The quantity named came out of 41 trays. As a matter of fact, double the number of trays of Apples can be stored in the fruit room in the course of the season if the latest varieties are kept out of it until the end of November, while less late varieties are being marketed. Further evidence bearing upon the subject in dispute is afforded by the fact that even "drops," stored in great heaps wherever a place under cover could be found for the extraordinary quantity blown off the trees by gales, kept at least as well as "drops" in trays. It is doubtful whether any more rotted, and certainly there was much less shrivelling in the heaps. *Southern Growers.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 15. The first meeting of the Royal Horticultural Society in the New Year took place on Tuesday last, in the Drill Hall, Buckingham Gate, Westminster. The exhibition was small, but there was a good attendance of visitors.

Of the few exhibits, Orchids formed the majority, there being, besides, only a group of Carnations, a stand of dried Beans of the Haricot type, and a few floral paintings.

Floral Committee.

Present: Messrs. H. B. May (in the chair), Geo. Paul, John Heal, W. J. Bean, J. Green, W. P. Thomson, J. W. Barr, C. E. Shea, W. Howe, C. Dixon, H. J. Jones, C. R. Fielder, E. F. Hazelton, G. Reuthe, S. Morris, R. C. Notcutt, James Hudson, J. Jennings, W. B. Cranfield, Chas. E. Pearson, E. H. Jenkins, and J. F. McLeod.

AWARD OF MERIT.

Carnation Dr. F. C. Ward.—A variety of the perpetual flowering type, with a moderate sized, well-formed bloom of rose-cerise colour. The stems are stiff and stout, whilst the calyx is perfect. Shown by F. C. Stoop, Esq., West Hall, Byfleet (gr. Mr. G. Carpenter).

GROUP.

The only collection staged was an exhibit of perpetual flowering Carnations by Messrs. Allwood Bros. Their new variety Marion Wilson was shown, and there were also excellent blooms of the cerise-coloured Destiny. (Silver Banksian Medal.)

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Messrs. Jas. O'Brien (hon. secretary), W. Bolton, A. Dye, Walter Cobb, J. E. Shill, J. Cypher, Frederick J. Hanbury, J. Charlesworth, A. McBean, C. H. Curtis, T. Armstrong, Fred. K. Sander, Pantia Ralli, R. G. Thwaites, J. Wilson Potter, and C. J. Lucas.

AWARD OF MERIT.

Laelio-Cattleya Ounius Bryndir variety (see fig. 13, p. 27) (*L. C. Ounius* × *C. Enid*), from Dr. Miguel Lacroze, Bryndir, Roehampton. A well-formed flower of exceptionally attractive colour. The sepals and petals are Apricot-yellow with a slight rose shade, and the lip vinous-crimson with gold lines from the base to the centre.

Cypripedium Matthewsianum Usk Priory variety (*Thalia Mrs. Francis Wellesley* × *Hera Euryades*), from R. Windsor Rickards, Esq., Usk Priory, Monmouthshire.—The flower, in its colouring and perfect form, is nearest to C. Thalia Mrs. Francis Wellesley. The dorsal sepal is white, with small emerald-green base and many lines of claret-purple spotting, changing to rose in the smaller spotting towards the margin. The petals and lip are tinged with brownish-purple, the margins being pale yellow.

PRELIMINARY COMMENDATION.

Odontoglossum Apollo (*Armstrongiæ* × *Queen Mary*), from Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells.—One of the finest of a dozen new Odontoglossums flowering for the first time staged by this firm. The large flower had a blush-white ground heavily blotched and tinged with reddish purple.

Odontoglossum Peerless Orchidhurst variety (*Ossulstonii* × *crinitum*), from Messrs. Armstrong and Brown.—The flower is dark claret purple with white margins and tips to the segments. The second of the cross to receive commendation.

GROUPS.

The Duke of Marlborough, Blenheim, Woodstock (Orchid grower Mr. J. Smith), exhibited Cypripedium Curtingo (Curtisii × Flamingo), a very distinct hybrid with purple tinted, dorsal sepal, having a broad white margin; and C. Leucurtis (Leeanum × Curtisii), with an attractive flower.

R. Windsor Rickards, Esq., Usk Priory, Monmouthshire, showed Cypripedium Euryiades Mirium, a noble flower of fine shape; and C. Commodore (Memoria Jerninghamiæ × Alcibiades illustre).

Dr. Miguel Lacroze, Roehampton (Orchid grower Miss Robertson), staged a finely flowered specimen of Odontioda Madeline, Bryndir variety, the large flowers having a pale yellow ground densely blotched with Indian red.

Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, were awarded a Silver-gilt Flora Medal for a group of Odontiodas, Odontoglossums, and other Orchids.

Messrs. Charlesworth and Co., Haywards Heath, were awarded a Silver Flora Medal for a group rich in their handsome hybrid Orchids, chiefly Odontoglossums and Odontiodas.

Messrs. Jas. Cypher and Sons, Queen's Road Nurseries, Cheltenham, were awarded a Silver Banksian Medal for a group of Cypripediums with white Laelia anceps, white Calanthe Harrisii, and white Cypripediums.

Messrs. J. and A. McBean, Cooksbridge, were awarded a Silver Banksian Medal for a group in which their famous strain of Cymbidiums were a feature.

Messrs. Hassall and Co., Southgate, were awarded a Silver Banksian Medal for a group of Cymbidiums, the finest being C. Capella magnificum (Wiganianum × Parwelsii).

Messrs. Sanders, St. Albans, showed Cymbidium Albatross (Gottianum × grandiflorum), with cream white flowers lined and dotted with reddish rose.

Messrs. Flory and Black, Slough, showed Odontoglossum La Seine, a showy hybrid of un-

recorded parentage, with light claret red flowers with a narrow blush-white margin.

WALTER COBB, Esq., Normanhurst, Rusper, showed a well-flowered plant of Miltonia Phalaenopsis Cobb's variety.

Fruit and Vegetable Committee.

Present: Messrs. W. Poupart (in the chair), H. S. Rivers, A. W. Metcalfe, W. Bates, Ed. Beckett, O. Thomas, Ed. Harriss, A. Bullock, P. D. Tucker, F. Perkins, W. H. Divers, A. R. Allan, E. A. Bunyard, and F. Jordan.

AWARD OF MERIT.

Apple St. Cecilia. A medium-sized fruit, of strikingly handsome appearance, said to have been raised from Cox's Orange Pippin crossed with an unknown variety. The seedling showed evidence of Cox's Orange Pippin in its general appearance, with rather more colour, and more conical shape. The flesh is solid, juicy, and of excellent flavour; the stalk is rather deeply set, and somewhat slender. The eye is shallow. The variety is one of the best new dessert Apples of recent times. Shown by Messrs. JOHN BASHAM AND SONS, Bassaleg, Newport, Mon.

DRIED BEANS FROM WISLEY.

An exhibit of much interest was shown from the Society's gardens at Wisley, a collection of dried Beans of the Haricot type. The cropping qualities of the several varieties were demonstrated, the amount of produce obtained in each case from one ounce of seed being indicated. The best cropper was the Dutch Brown, which gave 2 lb. 15 oz. from one ounce of seed sown. This was followed by Long White Canterbury, with 2 lb. 11 oz.; Long-podded White, 2 lb. 9 oz.; Glory Butter (of a pale liver-colour), 2 lb. 6 oz.; Ecclesiastic (a buff-coloured variety), 2 lb. 5 oz.; Jaune Cent-pour-un (pale brown), 2 lb. 5 oz.; Gris Maraicher (mottled), 2 lb. 4 oz.; Cent-pour-un (same colour as Dutch Brown, but smaller), 2 lbs.; Comtesse de Chambord (pearly white), 1 lb. 15 oz.; Perfection (black and white, 1 lb. 11 oz. The samples were exceedingly good, and the exhibit amply demonstrated the possibility of growing and drying Haricot Beans in this country.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 5. *Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. Cypher, J. Howes, A. J. Keeling, D. McLeod, J. McNab, W. Shackleton, H. Thorp, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cypripedium Persius, a well-shaped flower, the round, dorsal sepal being 3 inches across, with a white ground, heavily spotted crimson; the broad petals are mahogany red; and *C. Persius* var. *Beta*, the dorsal sepal is almost solid crimson, with white margin; lip and petals honey-yellow veined crimson, both from W. B. LEE, Esq.

C. Christopher var. *Grand Duke Nicholas* (*Miss Canon* × *Lucasiana Canona*), a large flower of perfect shape, the dorsal sepal measuring 4 inches across, porcelain-white, with a green base and numerous white spots, the lip and petals are greenish-brown; from S. GRATRIX, Esq.

AWARDS OF MERIT.

Cypripedium Pyramus (*Leeanum* var. and *C. Sir H. Burdinson* (*Actaeus* × *longipetalum*), both from S. GRATRIX, Esq.

C. Gloria (*Actaeus* × *longipetalum* × *Golden Glory*) and *C. Golden Dawn* (*Golden Gem* × *Sun Tedrum*), from T. WORSLEY, Esq.

Odontoglossum crossum Perfection (*crispum Perfection* × *andersonianum*), from Dr. CRAVEN MOORE.

GROUPS.

The following medals were awarded to collections:

Large Silver Medal to W. B. LEE, Esq. (Rex Wood (gr. Mr. Branch). *Silver Medal* to Messrs. CYPHER AND SONS, Cheltenham.

SOUTHAMPTON ROYAL HORTICULTURAL.

JANUARY 9.—The annual general meeting of the above society was held on the 9th inst., at the Municipal Offices. The Mayor, Mr. Councillor A. W. Pearce, J.P., presided.

The Chairman of the Council, Professor Lyttel, M.A., submitted the 55th annual report, which stated that nearly 3,000 visitors attended the summer show. A floral bazaar held on the occasion for the benefit of the Red Cross and Order of St. John realised a net profit of £50.

The total receipts for the year amounted to £516 5s. 3d., and the expenses to £392 19s. 11d., leaving a profit of £123 5s. 4d. on the year's working, whilst the total assets are over £153.

It had been decided to hold a Rose Show at South Stoneham House on June 26, a fruit, vegetable, and Carnation Show on the Pier on July 23 and 24, and an Autumn Show, mainly to encourage local food production, on October 15 and 16.

CROPS AND STOCK ON THE HOME FARM.

OATS.

(Concluded from p. 20.)

WHERE the soil is dry and cloddy more harrowing and rolling will be required; light soils cannot well have too much work behind the sowing, as the repeated treading of the soil with the horses makes a firm and an advantageous seed bed. In stiff, wet soils less work is wise, as such soil should not be kneaded too much. For Oats I prefer to see a smooth rather than a cloddy surface. In the latter the seed germinates irregularly, and when rolled later many of the plants are buried by the clods and never come through again.

Where rooks are troublesome it is a good plan to dress the seed with some preventive such as Corvusine. Some find a difficulty in preparing the seed with this mixture, finding it rather "sticky" to handle. If a tin of Corvusine is stood in hot water for twenty minutes it will be found that when warm no difficulty will be experienced in mixing it with the seed, and the latter can then be sown easily and at once.

In newly-ploughed grassland much harrowing is necessary behind the sower to obtain sufficient tilth to bury the seed properly and provide a firm base for the roots as well as to hamper the progress of wireworms as much as possible. To aid this a heavy roller should be drawn over the plot several times alternately with harrows.

The quantity of seed required per acre varies considerably in different localities and circumstances. Where seed is sown from home-grown stocks it is wise to reject the small seeds by screening, as these tiny Oats, so common in some samples, cannot produce such vigorous plants as full-sized Corn. Seedsmen prepare their seed so well by screening that small seeds are never seen in their samples; they evidently prefer the more even-sized grain. In the general seeding of Oats of the Tartarian variety I sow four bushels per acre, sometimes five where birds are likely to be troublesome in outlying fields and where the land is, perhaps, in moderate condition only. Oats do not require so much space as Wheat; the tillering properties are not so pronounced as in Wheat, therefore the plant requires less room.

In extra rich soil, say, behind sheep with cake-fed roots, leaving a good dressing early in the season, three bushels of seed would suffice. Some of the stronger growing varieties require a greater distance, and three bushels would suffice. Some persons sow only 2½ bushels. I am a firm believer in plenty of seed as a safeguard against the many pests farmers have to contend with. As to variety, much depends upon requirements and local fashion. In some counties White Oats only are grown; in others Black. Black Tartar (Avena orientalis), which was introduced into Britain at the end of the eighteenth century, is the oldest of present-day popular varieties, and in some counties the principal Black Oat grown. In favourable seasons it yields as many as twenty sacks per acre, often weighing 42 lbs. per bushel. The ear, or panicle, grows one-sided. The straw is the most valuable of all Oats as food for cattle or for cutting into chaff for horses.

Messrs. Garton, of Warrington, have been most assiduous in raising new varieties of Oats during the past twenty-five years, including that popular White Oat Abundance, one of the best of White Oats grown. It is the result of a cross between White Angust and White Swedish. Other White varieties possessing much merit are Leader and Hero. From the same firm came Storm King, Yielder, Bountiful, and The Goldfinder, all desirable black varieties. For late sowing White Waterloo is excellent.

Hallett's and Bennett's strains of Black Tartar are no doubt very desirable where the Black Tartarian Oat is required. The Thousand Dollar Oat was introduced from America and re-selected by Professor Middleton, of Cambridge University. *E. Molyneux.*

Obituary.

JOHN LEEMANN.—Following closely on the death of Mr. Elijah Ashworth and Mr. Oswald O. Wrigley, both well known names in the Orchid world, we have to record the death of Mr. John Leemann, of West Bank House, Heaton Mersey, Manchester, which took place at his residence on the 14th inst., in his 75th year. The West Bank House collection of Orchids was one of the oldest and best in the Midlands, and has been frequently referred to in our columns. Mr. Leemann had a special liking for fine Odontoglossums and rare varieties of Cattleyas, a full collection of white forms of which was included in his collection. He was a Fellow of the Royal Horticultural Society, and frequently exhibited plants before the Orchid Committee, securing awards for some of them. Of late years he has been more closely in touch with the Manchester and North of England Orchid Society.

ANSWERS TO CORRESPONDENTS.

ANNUALS FOR CUT BLOOMS: *L. H.* Sown in autumn for spring, and again in spring for summer and autumn flowering, Antirrhinum, Nelrose, Clarkia, Firefly, and Stock-flowered Larkspur in variety. In spring, for flowering the same season, sow Aster, Comet and single, Chrysanthemum Morning Star, Eschscholzia in variety, Godetia Schamnini fl. pl., Nasturtiums The Pearl and Aurora, Shirley Poppies (several times), Sweet Scabious, Sweet Sultan, and in autumn, for spring flowering, Schizanthus wisetonensis, Mignonette and Sweet Peas should also be included in the list of kinds grown.

NAMES OF FRUITS: *H. E.* Apple Round Winter Nonesuch. *G. A. W.* Bruised and very poor fruits; cannot be identified. *R. W. R.* Round Pear Broom Park; large Pear decayed. (Thanks for 2s. for R.G.O.F.—Eds.) *F. C.* 1, Newtown Pippin; 2, Court Pendu Plat; 3, Allington Pippin; 4, Small's Admirable; 5, Margil; 6, Hanwell Soaring.—*W. B.* Apple not recognised; most likely a local variety.

PEAS UNDER GLASS. *E. L.* As the bed is 4 feet wide, you will be able to grow two rows of Peas in each bed, allowing a space of 2½ feet between the rows. If the bed is 4 feet from the roof-glass, varieties that grow 2½ feet high such as Early Giant and Daisy would be the most suitable. If the space is 5 feet, Gradus and Duke of Albany would be suitable. Dwarf varieties such as Harbinger and Little Marvel would give good returns, but these should be grown within 3 feet or 4 feet of the roof-glass. Do not sow the seeds thickly. Use rich soil mixed with a little decayed manure, and make it moderately firm. When water is necessary, give sufficient to moisten the bed thoroughly. Very little fire-heat is required; a temperature of 45° at night will be warm enough in cold weather. Air should be admitted freely in mild weather, but cold draughts are harmful, favouring the spread of mildew.

PLANT COLLECTING IN CHINA.

SHIEMALATSA, TSEDIRONG, UPPER MEKONG, VIA WEI HSI, N.W. YUNNAN

SINCE our arrival at Shiemalatsa the weather has continued very dry and warm. There is every sign of a third year's drought—a serious affair for the inhabitants of the valley, but there is a plentiful supply of moisture on the ranges from daily rain and the melting of the snows, so the Alpine flora will not suffer, though, as a result, the seed harvest may be earlier. Daily the lower valley is like a furnace; scarcely a breath of wind, a sky so intensely blue as to make one blink, and a sun, for brazenness excelling anything I have ever experienced. The climate resembles that of Mandalay; yet, on the ranges, above 9,000 feet or so, the air is cool and bracing, with lots of snow about, and, as I say, an abundance of moisture. Of course, it is all caused by the range acting as a rain screen. It is a trying country to work in, the changes of temperature are so great and the slopes of the mountains so steep and broken. I shall be very pleased when the season ends and I can get off south.

As I mentioned in my last letter, the Tibetan province of Sarong is only a day's journey to the north. There the most prominent features of the Salwin Mekong divide are the two sacred mountains Doker-la and Ka-gwr-pu, to which numberless Tibetans make yearly pilgrimages. The latter is pronounced "Karki'bu," though I spell it as given on the maps by Davies and Ryder. Two parties of my men have been up there recently, but judging by the results, and the information they give me, it does not appear to be a very productive area.

They tell me both mountains are very rugged—they certainly appear so from a distance—broken cliffs and jagged peaks and spurs, huge areas of dwarf cam and rock taking the place of the rich alpine meadows we have at this latitude. The country is taboo to me, this season at least, as I am bound by a promise to the Consul and the Chinese officials not to enter actual Tibetan territory. I regret this very much, as I should have liked to secure photographs of the region and the people. The herbaceous material my men brought back was not particularly interesting, it included a new Meconopsis, after the M. bella type, a number of Senecios, Cremanthodiums, Gentians, Saussureas, and a cushion Primula akin to P. dryadifolia. Of lower level shrubs there were only a very few, the most striking and worthy of mention being a new Lonicera, allied to L. xerocalyx, with yellow flowers and pale orange fruits. Of Rhododendrons they secured fourteen species new to me, but, unfortunately, the majority were in fruit, and of two only foliage was collected. One of the latter is a shrub of 9-12 feet, with bright green, bullate leaves, as seen in R. bullatum Fr., and a heavy grey-white tomentum. The young wood is also heavily tomentose, and from the description given it must be a very handsome shrub. I mean to make every effort to find a plant in flower or fruit, and have ordered my men to make a most exhaustive search. The other parties who were over on the Bei-ma-Shan were more successful, and made a fine haul of herbaceous material: Aconitum, Delphinium, Trollius, Aster, Senecio, Cremanthodium, Saxifraga, Gentian, Meconopsis, Anemone, Primula, Androsace, Potentilla, Corydalis, Draba, and several other good crucifers. One of the best finds they had was a Boraginaceous plant, which I cannot place. It is a lovely thing, and I have every chance of getting seed of it. A cushion plant of 6-12 inches diameter, or even more, its habitat is on cliffs and boulders and stony screes at 14-15,000 feet. The foliage is small, imbricated on the stems, coated and fringed with silvery, glistening hairs; the flowers are stemless, solitary, and embedded in the foliage at the end of each stem, brilliant blue, and about the size of those of Cynoglossum amabile. The flowers are freely produced, and it is the finest thing of its kind I have seen for some time.

One of the Meconopsis collected was that which I have in fruit only under No. 13,169 of the 1914 collection. In habit it much resembles a dwarfish M. integrifolia, but the whole plant, and especially the capsule, is smothered in golden, shining, rather bristly hairs, never seen in the type. In determining the Meconopsis of 1914, Sir D. Prain put down No. 13,169 as M. integrifolia. I have little knowledge of the genus excepting from a collector's standpoint, and there I for cannot dispute his decision, but it must be a very distinct variety, for the flowers are white and smaller than those of the type integrifolia. However, I hope to secure seed, and if you are successful in flowering the plants the point will easily be settled. (The Bei-ma-Shan is a portion of the Mekong-Yangtze divide.)

Another party of men went far south on this divide, principally to find the original type of Meconopsis speciosa as seen by me in August, 1905. They were successful, and I shall, if all goes well, collect abundance of seed. I have no knowledge of the Himalayan Meconopsis, but Meconopsis speciosa is the only species in Yunnan which is scented. It is deliciously fragrant, the fragrance resembling that of our own Dutch Hyacinths.

Altogether since we came here we have been most successful, and if I bag seeds of all the finer things I have found I shall be most pleased. The Herbarium numbers fully 1,000 species from Tengyueh, to date that is, and that takes some getting when the total is over 14,000 species. I have excellent reports of my Tengyueh and Talifu men, discounting those at Lichiang, and their spoil should add another 500 species. In going over my field book I find Rhododendron comprises some 15 per cent. of the total, and over a certain altitude in N.W. Yunnan Rhododendrons dominate in the flora.

They are so numerous, species and varieties, that I now find myself in a perfect tangle over them, and have given up even attempting to group them in the field. Most of the species of which only incomplete material was collected in recent years I have secured, as well as those of Soulie and Monbeig's collections, and I find groups of species, or one may call them varieties for the time being, formed round such as R. saluenense, R. Forrestii, R. Roxeianum, R. floccigerum, and R. sanguineum. I have at least five or six fine forms akin to R. saluenense, and the same of R. sanguineum. If what I have found are only varieties, then these two species sport as much as the variable R. dichroanthum of the Tali Range, or even more so in the case of the latter. Of the first there is apparently a different form on every range and divide. Of course, it is impossible for me to deal with these differences here; they will have to be worked out very carefully. Any information I might now give would possibly add to the confusion later. The original type of R. Forrestii, that with the black-crimson flowers, and red under surface to the foliage, I have not, so far, rediscovered. All the plants I have seen, though having the habit of the type, have blooms of a brilliant crimson or cherry scarlet, and much larger leaves. However, I have found another distinct species with the same creeping habit, with lanceolate foliage, 1½ inch by ¾ inch, and pendulous flowers 2-3 in a cluster, of a soft, dull rose throughout; a very fine and most interesting shrub, but apparently very rare. R. sanguineum and its affinities have formed a magnificent group, all the members of which have splendid flowers and bear most freely. The type, which I introduced in 1914 has blooms of the richest scarlet, fleshy, and enamelled on the exterior, of large size and abundantly produced. It is a shrub of 1-3½ feet, the tomentum on the under surface of the leaves, short, adpressed, and silvery-white. Another, a form with identical foliage, has flowers black-crimson—the colour of dried bullock's blood. Yet another form or species in the same class has rose blooms lined with white down the centre of each segment of the corolla, with the base white, reminding one of the striped pink and white Camellias. Of this the tomentum is much heavier and of a light biscuit shade.

Another form has blooms of the same size and consistency as the type, but of a most delightful shade of lemon-yellow, without variation, the tomentum on the under surface of the leaves very heavy and soot-coloured. Another plant has pure white blooms, with a buff-coloured tomentum on the leaves. R. Roxeianum a new sp., collected in fruit in 1914, has blooms pure white, spotted vivid crimson. In occasional specimens the margins of the corollas are flushed rose. There are many forms in the foliage of this species, but no variation in the flowers. It does not run into R. protoroides, a new sp., also collected in 1914 in fruit only, flowers dried, of that I am now convinced. This last-named R. protoroides also varies very considerably in colour. The type, as seen in scanty specimens in 1914, is pale canary-yellow, beautifully marbled deep crimson. I have specimens bearing yellow, white, white flushed rose, and pure rose flowers. R. campylogynum is as variable as any, with flowers from almost light pink to the deepest plum purple, the type shade of the Tali plant. There is also great variation in size of foliage. I have specimens with leaves as large as those of R. hypolepidotum—number of flowers and stature of plant which is anything from 2 inches to 2 feet. I could write columns on what I have in hand, and what I have seen points to the fact that we are approaching very close to the optimum of the genus, which I reckon is not very far from here, probably some short distance N. and N. of the mountains of Sarong.

NEW PRIMULAS.

What I write of Rhododendrons applies also to the genus Primula. I find groups of new forms, or sub species, collected round the types. I have found what I take to be a new species of the section Omphalogramma, and I expect many others will be discovered yet. There must be connecting links between P. Elwesiana of the Himalayas and those we know here. All the rock and bog species of the high alps, such as P. dryadifolia, P. bella, and P. amethystina, are, I find, the nuclei of groups of species or varieties, a point to be settled later. I have five plants all distinctly related to Primula dryadifolia, and yet

quite apparently distinct from the type. The same applies to the known members of the Nivalis section; quite a group has formed round the beautiful P. calliantha. Of them, one lovely plant was brought in recently, which, with the foliage of the calliantha, has much longer and more slender scapes, each bearing 2-5 blooms of the most enchanting shade of lake-carmine, with the eye dull grey, each bloom 1½-1¾ inches or even more in diameter, and deliciously fragrant. A glorious plant! Another, equally fine, of the calliantha group, has lovely rose-pink flowers.

I have so much to attend to at the base that I do not get out much. Last week I was out for three days on a portion of the Range totally new to me. The first day we had a most exhausting climb of 6,7,000 feet, a steady grind from 6.30 a.m. till four in the afternoon. The first part of the climb was through a thicket of rhododendron, mostly R. lepidotum, with a few R. anthopogon, R. setosum, and R. Wardii, and a few Primulas, P. Wollastonii, P. Forrestii, P. Bellidifolia, and P. Wardii. Then we came to the snow-line, and from there on to the top of the pass, 15,500 feet, we had a steep climb over snow and rock. The view from the top was magnificent, but I was too tired to enjoy it much. The descent was by a steep snow-slope, and then over a long moraine, and then down a steep grass-slope to the camp, which was pitched at 13,000 feet. The second day we had a long march down the valley, and then up a steep spur to a pass at 14,000 feet, and down the other side to a camp at 12,000 feet. The third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The tenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eleventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twelfth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fourteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventeenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The nineteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twentieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The twenty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirtieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The thirty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fortieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The forty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fiftieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The fifty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixtieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The sixty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The seventy-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eightieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The eighty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninetieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The ninety-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundredth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and tenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eleventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twelfth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fourteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventeenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and nineteenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twentieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and twenty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirtieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and thirty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fortieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and forty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fiftieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and fifty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixtieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and sixty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and seventy-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eightieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and eighty-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninetieth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The one hundred and ninety-ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundredth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and first day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and second day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and third day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and fourth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and fifth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and sixth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and seventh day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and eighth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and ninth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up a steep spur to a pass at 13,000 feet, and down the other side to a camp at 12,000 feet. The two hundred and tenth day we had a short march down the valley to a camp at 11,000 feet, and then a climb up

silvery shining surface, regularly spotted deep crimson. That is the type as seen on the Tali Range also, but there is another kindred plant here—both were collected on the Chungtien plateau in 1914, and introduced by me then, and may be seen at Edinburgh, where they flowered last season—not so tall, nor so floriferous, with coarser foliage and smaller blooms, not fringed, and suffused a dull purple-rose, with many minute crimson spots at the base. It is, I now consider, quite distinct from N. pardanthina. A rarer plant than any, with its Heath like blooms and foliage, is Diplachne multiflora Hook., of which several groups were seen on the barer rock surfaces. Owing to the nature of the weather I did not then have an opportunity to explore the full extent of the valley or beyond it. Therefore I write only of the spot where we camped. It rained steadily in sheets all that night, all the next day, and following night, and when we set out on our return journey it was raining *as* steadily, with clouds of driving mist half obscuring everything. I went principally to secure photographs of some of the best plants, and after sleeping and sitting drenched and miserable under a shelter of Pine branches for two nights and the greater portion of two days, was forced to take them under the existing conditions. They have been developed: some are fair, but most are very weak, especially groups and scenes. When I left Lichiang some of my men came here by a different route, via the Yangtze valley, Wei Hai, and the Li ti ping, to secure flowering specimens of species collected only in fruit in 1914. They also ascended a portion of the Kari Pass, east of Yeh chik in this valley, and were most successful, bagging many good things, besides most of those they were instructed to secure. Of their lot the finest is Rhododendron glischrum, a shrub which, when it flowers at home, will cause a sensation. Mr Williams has a stock of it from the 1914 seed I gathered. It is a magnificently foliaged tree species, with big trusses of large, campanulate blooms, of a most wonderful shade of plum rose, with crimson markings, and a deep crimson blotch at the base. Even the dried specimens are a delight. *George Forrest.*

GROWTH OF SNOWDROPS.

THE illustrations in fig. 14 show the same Snowdrop clump photographed annually on the first day of the year in a Norwich garden, to indicate the relative severity of the winters. The exceptional hardness of the present winter compared with those of recent years is shown by this year's record, in which the shoots are but just appearing above the ground. How greatly the seasons vary is indicated by the record of 1913, the photograph for that year showing the plants already almost in flower.

APPLE WILLIAM CRUMP.

I HAVE long looked for an Apple possessing merit that could worthily be classed as a successor to Cox's Orange Pippin. No Apple approaches Cox's Orange Pippin in quality during the months of December and January. By some it is considered a November Apple; it is not so, as by that time the fruit does not possess that fulness of flavour and quantity of juice it subsequently develops. By the end of January, however, these qualities are failing, except under exceptional circumstances of preservation, although it is possible to preserve the fruit until the middle of April.

The variety known as William Crump (see fig. 15) was raised by Mr. Crump, of Madresfield Court Gardens, from Cox's Orange Pippin (fig. 16) and Worcester Pearmain (fig. 17). It possesses the flavour of both parents, and the yellow-coloured flesh of Cox's Orange Pippin especially. In size the fruit is larger than Cox's Orange Pippin; it has splendid flavour, is especially firm in the flesh, and full of juice, combining sufficient sweetness and a crispness that finds much favour.

The colour is intensely brilliant crimson, not only on the sunny side, but all over. The growth is more vigorous than I at one time thought it to be. Some growers—nurserymen in particular—find the tree shy in fruiting, but an open exposure and thin training do much to increase fruitfulness.

In many respects this Apple reminds me of that handsome Californian variety, Winesap, which is quite one of the best of foreign Apples. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham.*

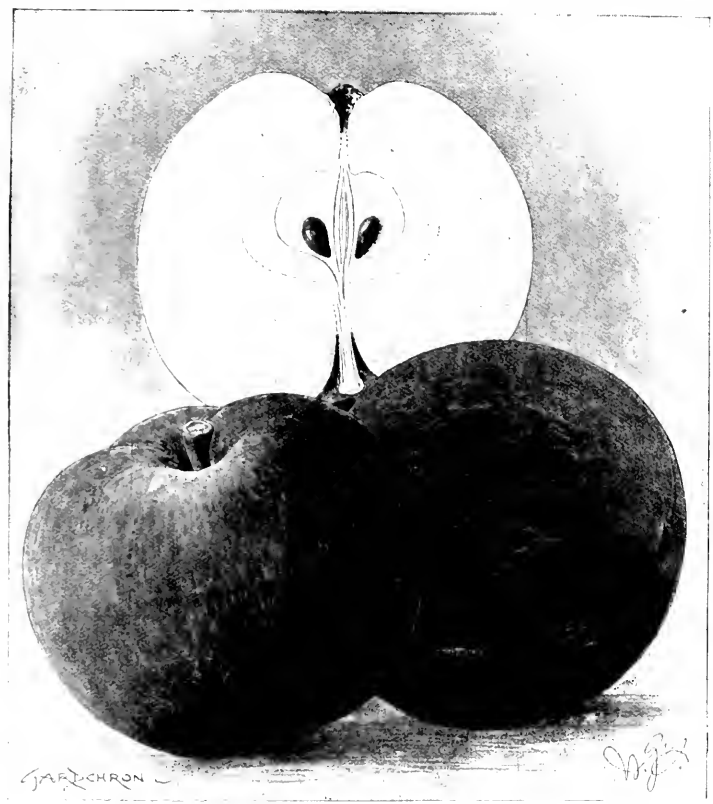

FIG. 15. DESSERT APPLE WILLIAM CRUMP.

ORCHID NOTES AND GLEANINGS.

NEW HYBRIDS.

LAELIA CRAWSHAYANA.—A very interesting cross between Laelia anceps and L. autumnalis, in which the latter is the seed-bearer, is sent by Mr. F. C. Puddle, Scampston Hall Gardens, Rillington. The flower bears a strong resemblance to L. Finckeniana, supposed to be a natural hybrid between L. anceps and L. albida, illustrated in the *Gardeners' Chronicle*, December 30, 1893, p. 804. The flower is interesting as disproving the suggestion of Reichenbach in *Gard. Chron.*, January 14, 1888, p. 41, that L. Gouldiana might be a natural hybrid of L. anceps and L. autumnalis.

It appears to be identical with Laelia Crawshayana Rchb. f. (*Gard. Chron.*, XIX., 1883, p. 142), the author holding that it was a natural hybrid between L. anceps and L. autumnalis, a contention which the present home-raised form seems to prove. L. Finckeniana may prove to be of the same parentage.

The flower sent is nearest to L. anceps in form and size, though intermediate in features. The sepals and petals are silver-white with a rose flush on the outer parts. The lip is white at the base, with fine purple lines on the side lobes, and the narrowly triangular front rose-colour.

COLOUR VARIATION.

MR. F. C. PUDDLE writes: "I wonder if we shall ever get to the bottom of the law of colour combination in hybrids? I am just flowering some home-raised batches of Cattleya Freya (Dowiana aurea × Mantinii) and C. Sylvia (Dowiana aurea × Fabia), and in each batch I have had flowers with yellow, white, and mauve sepals and petals. I have now the first flower open of a batch of Laelio-Cattleya Ingramii (C. Dowiana aurea × L. Dayana) × Cattleya Fabia (C. Dowiana aurea × C. labiata), and this has white sepals and petals. All these have Cattleya Dowiana aurea twice in their parentage.

Flowers sent to illustrate these remarks all have white sepals and petals with labellums showing rose and purple in varying degree, but tending to show that the colour of the petals of the parents had been eliminated, while the dark tints in their labellums had been changed to a much lighter shade. Colour in some crosses is known to vanish when crossed one way and to intensify in the reverse cross. It will be necessary in scientific records for future use that the male and female parent be indicated, so that reverse crosses may be made. In the

earlier years of Orchid hybridisation the seed bearer and pollen parent were recorded by the usual signs, but the information was in many cases unreliable, and the practice was therefore discontinued.

Mr. F. C. Puddle also sends a flower of Brasso-Laelia Moonbeam (B.-L. Jessopii × L. Dayana), pure white with a pale yellow disc to the lip, the Brassavola Digbyana in B.-L. Jessopii totally vanishing, the rose and claret-purple of the lip of L. Dayana, the yellow of L. xanthina, which was strong in B.-L. Jessopii, also disappearing, probably to return in the next crossing if a suitable combination is arranged.

LETTERS FROM SOLDIER-GARDENERS.

WHAT GARDENERS MAY LEARN FROM THE ARMY.

II.

INCINERATORS OR REFUSE DESTRUCTORS.

My last remarks under this heading evoked some comment and criticism. This is all for the good, for I am not writing dogmas, but suggestions. Now, there is nothing new about an incinerator. The novelty is in the word rather than the idea. It is probable that before the war the word never occurred in the plebeian vocabulary. Now, however, it has come to stay. It is an essential institution on sanitary grounds where a number of men are billeted, and I doubt not that many a soldier who takes to gardening will construct an incinerator for the burning of his garden rubbish, much in the same way as we have been accustomed to do it with the time-honoured smother fire. There are various types, according to the material at hand for construction. I will describe a few of the more common. An uncommonly good type is a square brick structure, roughly about 4 feet square and 4 to 5 feet high, provided with an opening at the bottom for draught and for withdrawing ashes; another higher up, which can be covered in with sheet iron, for piling in the refuse; a movable cover of sheet iron to keep down the flame; bars of iron to keep the fire above the ground; and a pipe or stack to take off the smoke. This could be cheaply constructed by anyone, and would prove an efficient method of disposing of rubbish, burning soil, and providing valuable ashes for the garden. Owners of a greenhouse would be quick to realise that the top would form a good place for warming, drying, and sterilising potting soil and for drying pots and boxes. In fact, my imagination runs so high that I am not so sure that, provided there were a sufficient amount of rubbish or earth to be burnt, we could not form a hot-bed over the top.

Another type which is often seen has simply a layer of bars about a foot from the ground and a square enclosure of sheet iron. This has no top, but one could easily be devised, as well as a chimney. Yet another type is a square or circular stack of open-work brick, by which I mean bricks built with open spaces between them. Usually, but not always, bars are provided. The bars are, of course, any iron that happens to be available, such as the uprights used for barbed wire, or iron window bars. This type is not covered in. A very crude kind of incinerator is sometimes seen which practically represents a wire-netting basket. Iron stakes are driven or secured into the ground; a bottom is made of strong wire netting a foot or so above the ground, and the sides also are enclosed with wire netting, so that we have what might be called a glorified brazier. Undoubtedly the best form for garden purposes is one that is solidly enclosed except for providing an inlet for draught and an outlet for smoke. It would prove a much neater contrivance than the old smother fire, and would equal, if not exceed, it in efficiency. *William F. Rowles. B.E.F.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

BROAD BEANS.—To obtain early pods of Broad Beans the seed should be sown at the first opportunity, as recommended last week under "General Remarks." The earliest sowings are most appreciated, as Broad Beans are not in much request when Peas and Runner Beans are plentiful. The varieties Beck's Dwarf Green Gem, Early Longpod, and Broad Windsor for the second crop, are suitable sorts to grow.

EARLY RADISHES.—Radishes may be grown amongst other early crops, or, better still, in separate frames, if any are available. The seed germinates rapidly, and should be sown thinly, or the plants will fail to "bulb" quickly. Let the plants receive as much sunlight as possible; the frames will not need much ventilation but all the light possible. For Radishes a frame may be prepared similarly to that intended for Carrots, sowing the seed broadcast, and covering it with a little fine soil. There are numerous good early varieties; a mixture of oval, turnip-shaped, and long-rooted varieties forms the daintiest dish.

FIG. 16.—APPLE COX'S ORANGE PIPPIN. (See p. 33.)

MUSHROOMS.—Too much artificial warmth, and especially during very cold, frosty weather, is a frequent cause of failure with Mushrooms in houses, and quickly exhausts the beds. A little extra fire-heat may be necessary if the weather continues wintry, but 50° should not be exceeded; in very severe weather a fall of 5° in the temperature will do no harm. Be careful not to use an excess of moisture; a gentle syringing with tepid water is generally all that is needed at this season, and when no fire-heat is used syringing will not be necessary.

LEEKS.—These vegetables usually keep sound very late in the season, and the crop should be reserved, as much as possible, as there will be a demand for them when the Onions have all been used. Leeks may be lifted and bedded in soil, but there is no necessity for doing this unless the ground is required for other purposes. If extra fine Leeks are needed for exhibition purposes, a pinch of seed should be sown at this date. Lyon is a popular variety for exhibition.

JERUSALEM ARTICHOKE.—The Jerusalem Artichoke often succeeds where other vegetables would fail, and the tubers provide an agreeable variety at a time when only a few kinds of vegetables are available. Although the crop succeeds with very little trouble, this should be no excuse for growing the plants on the same ground year after year; ground Artichokes pay for good culture and a change of soil. The plant is hardy, and should the weather and ground be favourable, planting may be done now. The crop succeeds best in deeply-dug but not excessively rich ground. The tubers should be planted about 10 inches apart, and the soil moulded over them; beyond an occasional cleaning of the ground, nothing further will be required.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

CHERRIES IN POTS.—The forcing of Cherry trees in pots must not be hastened unduly by an excessive amount of fire-heat. A night temperature of 40° to 45°, with a rise of 5° by day, will be warm enough to commence with, gradually increasing the amount of warmth when the trees are in flower. Admit air on all favourable occasions, and take care to ventilate the house freely during the flowering period, but cold draughts must not be permitted. Syringe the trees once or twice daily according to the weather, as a dry, close atmosphere would cause the young fruits to drop. Watering must be done with extra care; at no time should the roots suffer for want of moisture. Fumigate the house with a nicotine compound before the flowers open to keep the trees clear of black aphis.

THE ORCHARD HOUSE.—The orchard house should be cleansed thoroughly, and any necessary painting or repairing attended to at once. Arrears of pruning should be completed, as in most cases the fruit-buds are becoming prominent. Trees planted in borders should be carefully washed with an insecticide. Brown scale insects can generally be found on established trees growing in borders although the pot trees may be clear of the pest. The roots will soon be active, therefore the top dressings should be applied to both trees in pots and borders at once. It is not advisable to re-pot trees at this period; this work is best done in the autumn or just before the leaves commence to drop. The compost for top-dressings should consist of loam of a tenacious character, mixed with well-rotted manure, mortar rubble or chalk (some form of lime is necessary for all stone fruits), and sufficient bone meal to be noticeable in the mixture. Make the soil firm with the rammer, and allow space in the pots for future top-dressings. The protecting material should be allowed to remain around the pots for some time to come, or the latter may be cracked by the action of frost. During mild weather take the opportunity to give the borders a thorough soaking with clear water. As a preventive against attacks of green and black aphis fumigate the house twice before the trees are in flower.

TOMATOS.—The winter-fruiting Tomato plants will be benefited by light top-dressings composed of loam, decayed manure, and a little wood ash. Remove all superfluous foliage and expose the fruit to the light. Maintain a warm, buoyant atmosphere, with a free circulation of air. Succession plants in 5-inch pots should be placed in their fruiting pots directly they require more root space. A light compost made with loam, manure from a spent Mushroom-bed, mortar rubble, and a little bone meal will be suitable. Pot the plants moderately firm, and allow space in the pot for subsequent top-dressings. Place later plants near the roof-glass in a warm house having a temperature of about 60°. To provide plants for a further succession sow seed very thinly in pots, pans, or boxes, and germinate them in a temperature of 60°. Directly the seedlings are large enough to handle place them singly in small pots without undue pressure of the soil. Place the plants on a shelf near the roof-glass, and to prevent damping afford water sparingly until the plants are well established. Cold draughts will result in serious injury.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CYPRIPEDIUM.—Many of the late autumn and winter-flowering Cypripediums are passing out of flower. As soon as possible after blooming the plants should be examined, and any that require re-potting or dividing attended to. It is much the best time to divide the plants when they are being re-potted, as it can then be better seen how to carry out the operation without cutting through the roots, as every root is valuable to a divided plant. After the plants are broken up the strong growths should be selected to make large specimens, and the weaker ones potted into smaller pots. A growth that has flowered is the most valuable for propagating purposes, as it will often break into two or three shoots, whereas a new shoot will complete its growth before giving off other shoots. If it is not desired to increase the stock, plants that require increased rooting space may be shifted into receptacles two sizes larger than those they have occupied. Specimens already in large pots may be re-surfaced with fresh compost, first picking out some of the old soil from between the roots and replacing it with new material. All the strong-growing species, such as C. insigne and its varieties, Sanderae, Harefield Hall, Laura Kimball, and Sanderianum, also hybrids, including C. Thalia, Mrs. Francis Wellesley, Euryalus, Hitchinsiae, Beeckmanii, and Leeanum should be potted in a mixture of three parts good fibrous loam from which all the small particles have been removed, and one part peat or Osmunda fibre, with a sprinkling of crushed crocks to ensure the free passage of water. For smaller plants and less vigorous species, employ more peat or Osmunda fibre, adding a small quantity of chopped Sphagnum moss. The pots should be filled one-third their depth with material for drainage, this in turn being covered by a thin layer of coarse soil. The plants, and especially those that are pot-bound, should be watered thoroughly a day before being disturbed. After taking the plants from their receptacles, remove the drainage and all decayed soil from among the roots, and place them in the pots with the roots spread out. Work the compost between the roots, pressing it firmly and filling the pot almost to the rim. Take care not to break the roots. If the potting material is already moist, these newly potted plants will not require much water, but will be benefited by light sprayings overhead two or three times on fine days. When the roots have penetrated into the compost a liberal amount of water should be afforded them. Where a special house is devoted to Cypripediums the temperature should range between 55° and 60°. With sun-heat it may be allowed to rise 5° or 10°. Cypripedium seedlings should be placed in the warmest house, and potted on as they require it. Thrips are very injurious to these plants, attacking the young leaves. The insects should be destroyed by frequent fumigations.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

MORELLO CHERRIES.—In gardens where there is a considerable amount of wall space devoted to fruit trees, the Morello Cherries are frequently left until February before they are nailed or tied. With the shortage of labour the trees will probably be trained in many gardens even later than usual this spring, but so long as the work is finished some time in February no much harm will result. The Morello Cherry is one of the easiest of all wall trees to regulate and train. Strong young shoots from the base should always be retained, whilst old, stubby growths at the extremities of the branches should be cut away. The shoots should be trained in fairly thickly, as fruit-bearing spurs have not to be considered, as in the case of dessert Cherries. If signs of gumming are apparent, a slight coating of Stockholm tar over the affected part will be effectual in stopping the complaint. After the trees have been pruned and trained a winter dressing of liquid Gishurst Compound will assist in destroying the larvae of insect pests. Having done this work, lightly fork that part of the border nearest the trees, and apply at once a liquid dressing of concentrated manure (see last week's calendar) to assist the trees in the stoning period. I have had my best success with this fruit by simply securing the main branches to the wall and allowing all the fruiting wood to hang loose from the wall. The trees may not look quite so tidy as those trained in the orthodox manner, but fruit, not appearance, is the first consideration. I have found also that the fruits keep cleaner under this system. Standard Morello Cherries, after the Kentish system of culture, should be grown more extensively in private gardens. When well cared for these trees carry heavy crops of fruit, and the Cherries ripen somewhat earlier than those on north walls. The weeping form of standard tree is the best to plant; such a tree is easily kept in order by allowing the young shoots to extend and taking out the old, scrubby shoots. See that the main stems are secured firmly after the pruning is finished. Do not place farmyard manure close to these trees, otherwise the growth would be too gross. Those who may not have grown the Morello Cherry in grass orchards should make the experiment. I have seen most satisfactory results under this system of cultivation. May Duke and the Kentish Cherries are also suitable for growing as orchard trees in private gardens. Where the trees have been trained somewhat on the open system, without good results, I would advise the same treatment as is adopted for Morello Cherries, for I have tried it, and found the result satisfactory.

SWEET (OR DESSERT) CHERRIES.—In some gardens the pruning and nailing of Sweet Cherries may not yet have been done. If this is so I would advise that some consideration be given to the extension of growth, so that places bare of fruit-bearing spurs may be furnished with fruiting wood. Although the leaves of these Cherries are somewhat large, yet the growths may be trained fairly closely, as the leaves usually stand out horizontally. Rank, over-luxuriant growths indicate that there is too much manure in the soil. Should it be necessary to cut out gross-growing shoots, coat the wounds with styptic or cutting, and do not on any consideration apply new manures near to the roots, but rather starve the trees into a fruit-bearing condition. If the case be a bad one resort to root pruning.

PLANTS UNDER GLASS.

By F. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CARNATIONS.—Cuttings of Carnations that were inserted in November are sufficiently rooted for potting into 5-inch pots. The soil should consist of loam mixed with finely-broken brick rubble and sharp sand. Cuttings rooted later should be potted into 3-inch pots when they are ready for a shift. Recently potted plants should not be exposed to cold draughts, and should be watered with great care. With the lengthening days, old plants will be growing more freely, and it will now be safe to give the roots an increased amount of stimulant. Let the surface soil be carefully pricked up with a pointed stick, and afterwards apply a top-dressing of bone meal and soot. Admit plenty of air when the weather is favourable and use fire heat with moderation. Another batch of cuttings may be inserted if necessary. Plants of Souvenir de la Malmaison Carnations should be kept growing in cool conditions; afford water to the roots very sparingly.

CINERARIAS. Plants of the earliest batch of Cinerarias are coming into flower. If desired they may be grown in a little more warmth to hasten their flowering. The latest plants should be grown in a cool house, using fire heat only in times of severe frosts. Cinerarias need to be watered very carefully at this season; the pots are filled with roots, and the latter may be given diluted liquid manure or soot water occasionally. Examine the plants carefully for aphis, which is easily destroyed by light fumigations with a nicotine compound.

HIPPEASTRUM (AMARYLLIS).—Some of the most promising Hippeastrum bulbs may be placed in a light, warm house. First thoroughly soak the soil with water, then remove a portion of it to make room for a top dressing. The materials for this purpose may consist of loam, leaf mould, manure from a spent Mushroom bed, and sand. At this time of year it is wise to plunge the pots in a hot bed. Very little water will be needed till the plants are in active growth, but they should be sprayed two or three times daily with luke warm rain-water. Other batches of these bulbs may be started at regular intervals.

GLOXINIA.—The first batch of Gloxinia plants may be started into growth. Partly bury the tubers in boxes or pans of finely-sifted leaf mould, and place the boxes or pans on a shelf in the plant stove. When a little growth has been made shift the tubers into 5-inch or 6-inch pots, according to their size. A compost consisting of loam, peat, leaf-mould, finely-broken charcoal, and sharp sand, forms a suitable rooting medium for these plants. See that the pots are clean, and afford ample material for drainage. Seed may be sown now for raising a batch of plants for autumn flowering. The seed is very small, and to ensure it being evenly distributed should be mixed with a little very fine sand before sowing. Cover the seed-pans with a sheet of glass and place them in a propagating pit until the seeds have germinated.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

MYOSOTIDIUM NOBILE.—This fine plant has a name for ill-doing, and it was with some reluctance that a filled a warm corner with a number of strong plants and put others out in a rockery. Last winter we had, but on only one night, a frost of 26° to 29°, which destroyed those on the rockery, but the others recovered, flowered, and made good growth, with large leaves, through the summer. This winter the plants are protected as previously with tiffany sheets, which are lighter than those of canvas. From my experience with the plants grown in pots, it is clear that they are very gross growers. Hence I do not see that in the colder regions it will ever be possible to get results such as are obtained at Enys, or even at Logan House, in Galloway. The more vigorous the growth in summer, it is clear the more liable will the plants be to be cut off in winter.

HERBACEOUS PAEONIES.—The soil should be turned back from the roots of herbaceous Paeonies and a layer of row manure. The best is obtained in parks or meadows; spread evenly upon them, and the soil returned above the manure. Very large clumps are kept vigorous and prolific when annually surface dressed in this manner, cowdung of the kind recommended giving better results than are obtained from any other animal manure.

HELLEBORUS.—The earlier plants of Helleborus have been producing flowers for a long time, the great Christmas Rose (H. niger) having been much finer than usual. Not bigger, perhaps, but certainly with less tinted flowers. The later blooming varieties, if not already surfaced dressed, should be surfaced with any light, friable material. The compost should not merely be placed around the plants, but scattered amongst the leaves as well. Some of the species are very strong growing, and have root systems in proportion. These require much space and very liberal treatment, which results in tall and strong flower-scapes, abundantly furnished with flowers. The less vigorous species should be treated similarly to the true Christmas Roses, and all foliage removed that exhibits tendencies to unhealthiness.

EAST LOTHIAN STOCKS.—No delay should occur in raising plants of East Lothian Stocks if strong, abundantly flowering specimens are looked for. Means should be adopted in moistening the soil never to wet the surface of the compost, as the seedlings are very liable to damp off. Use a brisk heat to induce a rapid germination; but once that has been effected an intermediate or even a cool temperature is to be preferred. The best varieties for general purposes are those of white, mauve, and purple colours. Crimson, if of a good strain, is also worth growing, but there are many strains of dubious reliability in the market.

AUTUMNAL CROCUSES.—The surface soil should be lightly skimmed from about autumn Crocuses, and a layer of fresh material substituted before the current year's foliage begins to shoot; that is, of course, if the plants have been established long enough to need this attention.

EDITORIAL NOTICE.

Editors and Publisher. *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41 Wellington Street, Covent Gardeu, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.6

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, January 24, 10 a.m.: Bar. 30.2, temp. 53.5°. Weather—Fine.

Food Production by H.M. Forces at Home and Abroad.

In the old-fashioned wars armies were accustomed to live—to a greater or less degree—on the country in which they fought. The national armies of to-day, with their enormous requirements, need the resources of the world for their provisionment. Nevertheless, the longer the war continues and the greater become the demands which the armies make on food and transport, the more are they driven, in a new sense, "to live on the country." But the only way to do this is not to requisition, but to produce, and it is interesting to find that a national army can no longer devote itself solely to the work of destruction, but must undertake work of construction also. It is easy for the critic to protest that the work of food production would be better done if those whose work in life it is to produce food were left in that occupation. Of course it would be better; but the fact remains that none of the combatants in the present war has been able to pursue this better course. Each of the combatant nations has had to drain its man power away from the land, and each has had to return again to the land many of the men which were absorbed into the Army. In this country the carrying out of the programme of food production depends largely on the man power released by the Army. But in addition to this "better way," there is another supplementary method of food production which, when judiciously and cautiously used, should prove of great assistance in providing food and saving tonnage, and that way, of course, is for the armies themselves to become producers of food—to turn the swords into ploughshares. Needless to say, like so many excellent ideas, this one appears by no means easy of application—except to the doctrinaire, to whom all things seem easy. Military duty, frequent movements from place to place, provision of reserves for emergencies, the multifarious duties of road making, water supply, transport, and the like, have all to be taken into consideration. In spite, however, of the difficulties, the British Armies have found it possible to do a large amount of cultivation behind the lines in the various theatres of war. This work began in a somewhat sporadic way, and in many cases more as a means of satisfying our British love of gardening than in response to a recognition of the importance of increasing food supplies. Now, with the evident need for production of food and reduction of tonnage for the carriage of foodstuffs, it is being systematised and extended in the zone occupied by the British Armies in France. What we may call the agricultural activities of the Armies of France fall into three categories: the cultivation of Army gardens, assistance to French cultivators in the British zone, and the establishment of Army farms. The supply of seeds and seedlings for the camp gardens is being assisted by a number of pépinières (nurseries) established by the French authorities, in accord with our own, in convenient distributing centres. In these gardens large numbers of transplantable seedlings are being raised, with the object of supplying the requirements of the many camp gardens which are already in existence, as well as those of new camp gardens which are likely to be established.

The assistance which the Armies in France have given during the past years of the war has been considerable, and is, needless to say, greatly appreciated by the French farmers who have resumed the cultivation of their lands, and who are often sadly short of labour. The third means of increasing production, that of establishing Army farms, is evidently only to be resorted to when, for one reason or another, considerable areas of suitable land are likely, if not occupied in this way, to be left uncultivated. The limiting factor to any such scheme of cultivation is, of course, labour; but we may be sure that the genius for organisation which is shown by the British Army will be able to supply sufficient labour, skilled and unskilled, to bring many acres of unused land into cultivation, and thereby to make a valuable contribution to the food supplies of the Armies. When we turn to consider the Armies at home, it is evident that the first claim on their assistance, so far as food production is concerned, should be for helping farmers short of labour, and we are glad to know that the military authorities are fully alive to the importance of the Army giving all the help possible. Over and above this form of help, the Home Armies are doing notable work in the cultivation of camp gardens. This work, we believe, will be extended during the coming year, and we hope that, by the establishment of seedling-raising nurseries, it will be possible to secure a considerable increase of the areas under vegetable crops. Nurserymen would readily undertake the work of seedling-raising, and the frames and glass in their possession would enable them to do it with rapidity and economy.

The next few months are months of vital importance, for during that time much more land must be brought under extensive and intensive cultivation if Scarcity, now a visitor, is not to become an inmate of our households.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of the National Chrysanthemum Society will be held at Carr's Restaurant, Strand, on February 4, at 6 p.m. It is proposed on this occasion to present the late secretary, Mr. RICHARD A. WITTY, a testimonial in recognition of his services.

"SCOTTISH JOURNAL OF AGRICULTURE."—Under this title the Board of Agriculture for Scotland will issue a quarterly official journal containing articles, notices, etc., relating to agriculture, forestry, and other subjects of rural interest in Scotland. The first number will be published at the end of the present month. The price of the journal will be 6d. per copy, and the annual subscription 2s., or with postage 2s. 8d. Copies may be obtained through booksellers, or direct from H.M. Stationery Office, 23, Forth Street, Edinburgh.

CUNDALL MANOR TO BE SOLD.—The *Times* reports that Lord FURNESS has decided to sell his Cundall Manor estate by auction, and has instructed Messrs. KNIGHT, FRANK and RUTLEY to offer it at an early date. The estate is situated between York and Darlington, and comprises about 1,300 acres, with a good manor house, 10 farms, the village of Cundall, and some well-grown woodlands.

SUGAR FOR JAM-MAKING.—Those who grow fruit, and who are accustomed to use part of it for jam-making, should take note of the announcement made by the Ministry of Food that an allocation of sugar for this purpose cannot be counted on this year. The economical should be able to save a certain amount of sugar from the weekly ration, which is considerably larger than the German ration, and by using the sugar thus saved with glucose and a little saccharin, should yet be able to make a certain amount of jam. We may take it that the announcement is due in part to the probable shortage of sugar, and in part to the fact that a large proportion of our home-grown fruit will be required for pulping, and that all the pulp so made will be needed for jam-making to supply the Army and the civil population. Small fruit growers should therefore keep only such quantities of fruit as they require for their own use, and should make arrangements betimes for bottling or canning that part of their surplus which they cannot make into jam.

FOOD PRODUCTION IN FRANCE.—Three deputies, MM. COSNIER, COMPÈRE-MOREL, and LE ROUZIC, have been appointed by the French Ministries of Agriculture, Reconstruction, and Foreign Affairs respectively, to stimulate and develop food production. Monsieur LE ROUZIC, states the *Revue Horticole*, who was last year very successful in organising the production of Potatos, will now be chiefly concerned with increasing the cultivation of fruits and vegetables.

ONIONS.—Under the title "Controlled Absentees" the *Daily Telegraph* observes that control (as applied to foodstuffs) and disappearance are becoming almost synonymous terms. One of the latest illustrations on the subject is centred around the home-grown Onion. On Mon-

day, the 14th inst., the price of English Onions as fixed by law came into operation. Academically, legally, and so forth, English Onions were 5d. per pound; but it so happened that from the very day that attractive price was to rule there were practically no Onions obtainable except those from foreign lands, of which the price is unrestricted. Growers had ample warning that they were to be limited to 15s. a hundredweight on and after Jan. 14, so they hastened their sales whilst the market remained open and favourable. Most probably there will be a smaller crop of Onions next year. Farmers are not keen to grow them when the prospects of limited prices loom in the distance. Onions are a troublesome crop to raise; the cost of seed is enormously high, and, all things considered, Potatos are more profitable. French Onions have advanced steadily in price. Shopkeepers must now pay up to 35s. and 36s. a hundredweight, first hand, for them; whilst Spanish Onions at Covent Garden work out at an average of 35s. to 37s. for the same quantity. It must be borne in mind that the freight on Spanish Onions is about 30s. a case of approximately 120 lbs. The situation at present is that the public must be prepared to pay at least 5d., if not 6d., per pound for foreign Onions. In the past this vegetable was much too cheap to be appreciated: now that it is scarce and dear many will realise that Dean Swift was right when he wrote:—

"This is every cook's opinion,
No savoury dish without an Onion."

FROZEN POTATOS.—Frozen Potatos should not be discarded, but dried sufficiently to extract the water content. The drying may be done in an ordinary oven at baking heat. The tubers should be sliced and spread out evenly and the oven door left open, leaving the Potatos until they are chip dry. Then they may be kept in a dry place for a considerable time. To use these Potato chips they should be boiled in just sufficient water to produce a mashed Potato result.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents).

DAMAGE TO TREES BY SNOW.—Serious damage was done by the recent snow to trees and shrubs in this locality, principally during the night of Tuesday, the 15th inst., and the following day. Many fine specimens were practically ruined. The trees which suffered most were Birch, Oak, Elm and Scotch Fir, large branches being twisted or snapped in an extraordinary fashion owing to the heavy weight of snow on them. Fortunately, at the time of writing (January 18), the snow is gradually disappearing, and many of the shrubs and small trees are already resuming their natural shape. *E. Beckett, Aldenham House Gardens, Elstree.*

THE STORING OF APPLES.—Mr. Beckett's reference on p. 8 to the often perfect preservation of fallen Apples found covered Beckett's reference on p. 8 to the often perfect preservation of fallen Apples found covered with leaves in the orchard in mid-winter leads logically to the conclusion that the nearest approach to similar conditions is the ideal to be aimed at for the proper preservation of late-keeping Apples. For some years I have kept my latest varieties, such as Bramley's Seedling, Northern Greening, Alfriston and others in the orchard until after New Year's Day. They are carefully stacked in heaps or clamps, of the shape of a Potato pit, on the short grass of the headlands, being placed in position by hand, and all bad or necked fruits rejected. The heaps are then covered with one thickness of brown paper, and over this is placed dried Bracken Fern, or grass to a depth of 1 foot, finishing off with a rough thatching of straw. Late Apples keep perfectly in this manner, and the method is particularly useful when a bumper season overtaxes the fruit-storing accommodation. Another advantage is that during a rainy fruit harvest Apples can be "saved" much more quickly, as boys can build up the clamps almost as quickly as men can pick the fruit, and once they are in position all danger of loss from wind-storms is over. Although it is advisable to leave out any doubtful fruits, yet even if a bad one is overlooked the rot does not spread in the heap to anything like the same extent that it does in a house. I have just taken the variety Alfriston into the fruit-room from the outside clamps, and in 7 or 8 cwt. of fruits there were not 2 stones of bad ones. I always instruct the pickers to drop all deformed, pecked, or badly spotted Apples under the trees, and then, about fortnightly during the season, these and all windfalls are gathered into sacks for the cider mill. Our cider makers paid £3 10s. per ton for this class of rough, otherwise unsaleable, fruit this season. Windfalls always keep much better if left where they fall until they can be sent away. They begin to rot at once if placed in heaps. Apples have kept wonderfully well here this season, and this I attribute to the unprecedented scarcity of small birds last summer. These usually peck a good percentage of the fruits, all of which afterwards rot in the store, besides spreading disease to their neighbours. Nearly all varieties of Apples bore heavy crops last season, the two exceptions here being Gascoyne's Scarlet Seedling and King of the Pippins. *T. E. Tomalin, Boshorough Gardens, Pilmoor, Ireland.*

We have a fairly large fruit room here, but were the Apples to be spread in single layers it would need to be extended to many times its present dimensions. As long ago as 1886, when writing in the *Journal of Horticulture* on "Keeping Apples," among other remarks I wrote are these: "I have proved that Apples keep quite as well banked up in heaps as they do laid out singly." In the same article it is mentioned how the fruits have to be gathered into large baskets, how the fruit is removed off the trees by lifting, not twisting, how the fruit room is freely aired, kept at a low temperature, with windows unshuttered, and how windfalls of late varieties with skins unbroken are also stored. The same methods have been continued to this day. A few days ago the fallen fruits were examined and found still in good condition, and windfalls of Northern Greening and Alfriston in past years have kept into April. An important point in the preservation of late Apples is not to gather them until they are fully matured. *R. P. Brotherston, Tynninghame Gardens, Prestonkirk.*

HORTICULTURAL DUG-OUTS.—Mr. Bowles' remarks on p. 177, Vol. LXII., conveyed to my mind the impression that he regarded some of the temporary buildings used in war as good enough for dwellings at home. There is no mention of the better arrangements for light and ventilation which he now states would be necessary. I thank him for the explanation, but may I ask him would such buildings, even improved as he states, compare well with a properly constructed modern cottage or bothy, and be favourably regarded not only by gardeners but the general public? One can but notice also that the house Mr. Bowles hopes to buy on his return is not to use his own words—"going to be a French dug-out nor a wooden hut." He intends having such a structure for use merely as a retreat, and not to live in. May one hope that if, in the future, Mr. Bowles is connected with the housing of workpeople, he will use as his standard of comfort and hygiene his own residence, and work up to that rather than down to a previously fixed minimum of outlay. *Sydney Lismore, Holm Leigh, Wateringville, Hants.*

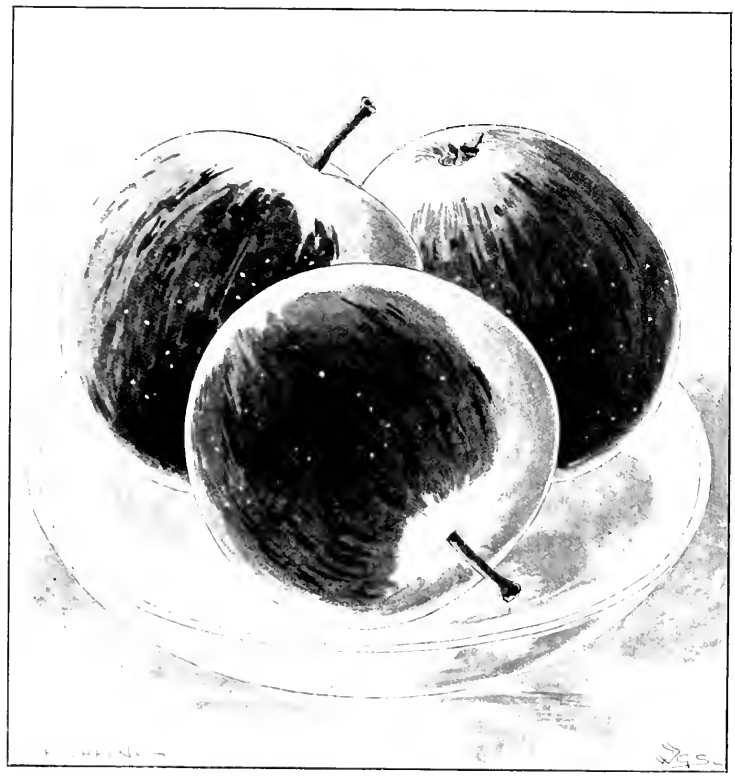

FIG. 17. APPLE WORCESTER PEARMAIN. (See p. 37.)

ON INCREASED FOOD PRODUCTION.

THE SOY BEAN.

JUST now, when all the food possible should be grown, I think it important to draw attention to the value of the Soy Bean, Glycine hispida, often known as Soya hispida (see fig. 18). This summer past, owing to its general economic importance, I have grown a small crop, and am much pleased with the result. How it compares with other Beans I do not know, but I have found the production in the Cambridge Botanic Garden equal to nearly 11 cwt. per acre. I have been interested in the Dutch Brown Haricot Bean distributed by the Royal Horticultural Society, and have grown a small crop of it also. In this case the crop per acre works out at about half that of the Soy Bean, but I refer only to one trial, and have to admit that half of the bed for some reason did not do perfectly well compared with the other half. In a circular just received from the R.H. Society it is said that the Dutch Brown Bean gives a yield as high as 60, and in some recorded cases, 100 fold. I have carefully weighed the quantity of Soy Bean that was sown, and find that the produce has been at the rate of 123 fold, though weight per acre is no doubt the most important consideration. My Soy Bean is of an old stock grown for many years in a small patch on the herbaceous ground. The seeds are black, and I mention this because it is a yellow-seeded form that is imported, and certain other attractive forms can be obtained. This black-seeded Soy, however, I have found much liked, and very satisfactory for table, though probably the yellow or brown might more generally be approved from the point of view of appearance. According to the best of my judgment it has a much better flavour than Haricot Bean. Vilmorin says in *Les Plantes Potagères* that the varieties in China are almost as numerous as the varieties of Haricots in Europe. In this work four kinds are enumerated—ordinary Soy, with yellow seed, the Etampes Soy, the early Soy of Podolia, and early Soy, with brown seed, the last two being the earlier kinds. It may be that the Soy plant in this country must be grown in the shelter of a garden and not in fields, but experiments would settle the question.

The Soy Bean is well known as being used in making the well-known Soy sauce, and this, until a recent time, was almost all we knew, but now it is described as universally useful. It can be eaten just as Haricot Beans are eaten, and is valuable for the oil it contains, which, according to an article in the *Daily Mail* of December 13, 1915, is used in the manufacture of at least fourteen different articles, from salad oil and margarine, to dynamite and soap. Among seventeen other products may be mentioned that of flour, artificial milk, cheese, and coffee substitute. It is said that if Germany is being allowed to import this Bean she is getting food for her men, her cattle, and her guns. The Chinese cultivated the plant for over 2,000 years, chiefly on the plains of Manchuria, and are said to have kept it to themselves. The Japanese apparently have the credit of realising the value and the possibilities of this Bean. The exports from China rose rapidly after 1903, so that now the Bean is second on the list of China's exports, with a value approaching £8,000,000. Germany very soon made enquiries, and, recognising its value almost at once, rescinded the import duty, and installed plant for the Bean in their oil mills, importing the Bean through Vladivostok, often in British ships chartered for the purpose. The yellow form is said to contain more nutritive matter than the other kinds, and the Bean exported is almost exclusively yellow. The quantity of oil extracted varies from 16 per cent. to 19 per cent. Writing in his book on Japan, after a visit to the Bean centres of Manchuria, Mr. Robert P. Porter says: "Only after one has travelled through the region where the Soy Bean reigns supreme, and has seen the wharves and the warehouses, the stations and the platforms, laden with bags of Beans, and noted the thousands of queer-looking stacks with pagoda-like roofs with which the country is dotted, and which serve as temporary storehouses for the produce while awaiting shipment, does one realise that it (the growth of the Bean trade) is not a fable, but a veritable fact in the history of international commerce. . . . And the manifold uses, agricultural and industrial, as well as dietary, to which the Bean can be put, invest this generous vegetable with increasing importance, and the future of the Bean crop with romantic mystery."

FIG. 18.—THE SOY BEAN.

A peculiar point, I note, is the changing shape of these Beans. Before they were quite ripe they were kidney-shaped. When dry, black, and ripe, they became round as a Pea, and on being soaked and cooked, they again showed the kidney-like form. *R. Irwin Lynch, Botanic Garden, Cambridge.*

ALLOTMENTS AT BIRMINGHAM.

IN the early part of last year the Parks Committee at Birmingham secured 630 acres of land, and parcelled it out into 6,280 plots. This year the Committee has obtained an additional 500 acres, which are to be divided into plots of 320 square yards each. This is a reduction of some eighty square yards on the size of the plots allocated last year, as it was noticed that many holders were not able to cultivate the whole of a 400 square yard plot. There is a keen demand for the new allotments, and further land will doubtless be acquired. It is computed that there will shortly be about 12,000 holders in and around the city. The local Press is doing its best to encourage this excellent movement. In particular, the *Daily Post* is raising a large fund out of which to provide the means for judging the allotments, holding a show of produce, and giving prizes for the best-cultivated plots. The Parks Superintendent, Mr. W. H. Morter, has the management of the scheme.

A LITTLE-KNOWN VEGETABLE.

CHENOPODIUM AMARANTICOLOR forms an excellent substitute for Spinach, and is, by many who have tasted it, preferred to that popular vegetable. The *Revue Horticole* describes its culture in France in an interesting article, stating that it was discovered about forty years ago, near Marseilles, by Honoré Roux, and placed in commerce in 1910 by Messrs. Vilmorin, Andrieux and Co. This plant is easily grown in almost any soil, but prefers a fair admixture of calcareous matter; it also needs plenty of warm sunshine. It is not affected by drought, which makes it an excellent subject for warm districts, like those around Marseilles, where Spinach is apt quickly to go to seed. It is being grown, however, with the greatest possible success, on an experimental farm near Juvisy (not far from Paris), by Monsieur Louis Sellé, gardener to the Union of Foreign Colonies. He states as follows: "The culture of the Chenopodium is of the easiest. I sow the seeds on April 15, pricking the seedlings out into open ground on the 25th of the same month. When the plants are sufficiently strong, usually about May 15 or 20, I transplant them to their permanent quarters. The plants do equally well in a dry or a damp place. Last year we commenced cutting in July, and the crop continued available until the first frosts."

CHINESE CABBAGE (see p. 27).

I BECAME acquainted with this vegetable through a note in *The Daily Chronicle*, where it was called Chinese or Celery Cabbage, and stated to be largely grown in Canada. I have since found that the plant is also known as Pe'tsia and Shantung Cabbage. It is the quickest-growing vegetable in the open with which I am acquainted. Seed sown out-of-doors on May 10 last season, between Roses, gave plants ready for use on July 20, each head weighing from 4 to 6 lbs. In shape the plant is somewhat like a Cos Lettuce, and the flavour when boiled somewhere between Lettuce and Cabbage. The vegetable was not highly appreciated by my employer, but in these days of limited food, the plant is well worth the serious consideration of all cultivators. If this vegetable could be grown for cutting from the middle to the end of May, from seed sown early in March, it would probably be useful as food for milch cows and other animals requiring green food, when grass is not always plentiful. Plants raised from seed sown in a border facing west on September 10 last appear to have withstood the recent severe weather quite well, although the young plants have been lifted by the action of frost, and the soil about them will need treading when weather permits. I am wondering if the plants of this sowing will go to seed instead of forming heads. Slugs are very partial to the young plants. *J. E.*

A PRIZE ALLOTMENT.

THE Rev. George Jack, St. Mungo's, South Leith, has won the Gold Medal of the Scottish Horticultural Association for the best allotment of 1917 in Edinburgh and Leith. The area of his allotment is one-twentieth of an acre. The total weight of produce amounted to 1,530 lbs., of which 783 lbs. consisted of Potatos. The market value was rather more than £8, and Mr. Jack's outlay was £3 3s. 4d.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 15. *Present:* Mr. E. A. Bowles, M.A. (in the chair), Col. H. A. Rawson, Messrs. W. Hales, W. C. Worsdell, H. A. Rawson, E. J. Allard, J. W. Odell, and F. J. Chittenden (hon. secretary).

Town refuse as manure.—Mr. Chittenden said he had secured an analysis of a sample of town refuse similar in appearance to that shown by Mr. Hudson at the last meeting, which showed a high content of lime, about 2 per cent. phosphate, and 1¼ per cent. nitrogen. Mr. Odell said he had also an analysis, and his showed a lower percentage of all these manurial substances than the one referred to. Experiments are being made at Wisley, Rothamsted, and Long Ashton to ascertain its manurial value.

Variation in shade of French Beans. Mr. Fraser showed seeds of the variety Mont d'Or, remarking upon the difference in shade of seeds of the same harvest. This difference is common in French Beans, and appears to be the result of differences in ripeness and of weather effect rather than of a constitutional character.

Oil-bearing seeds for cultivation in England. At the instance of Dr Keeble a discussion took place upon the kinds of plants which might be grown for their oil in England. They appear to be few, and none seems to produce a palatable oil. The oil bearing Flax, Rape, and other species of Brassicas, Sunflowers, Coreopsis, with perhaps some Malvaceous plants such as Malope and Lavatera, seem practically the only ones which are likely to succeed as oil producing plants in this country.

NATIONAL DAHLIA.

JANUARY 21. The annual general meeting of the National Dahlia Society was held on Monday last at the offices of the British Wholesale Florists' Federation, 35, Wellington Street, Strand. The president, Mr. Reginald Cory, was in the chair, and presided over a small attendance of members. The Committee's report for the previous year, which was read by the hon. secretary, stated that the membership was satisfactory, and that the exhibition held on September 11 had been a complete success. Other matters were referred to, including the awards made by the Floral Committee to new varieties, the competition for the Cory Cup, and the regretted loss by death of three members, Messrs. J. S. Stredwick, E. J. Such, and J. L. E. Lowles. The Committee had decided to discontinue the holding of conferences and the publication of the Dahlia Year-book. Lists of new varieties and selections of the best sorts in the various types were compiled and published in the Schedule for 1917. Regarding the Cory Cup competition, the conditions to be observed in future had been simplified. With regard to finance, the income of the Society during 1917 was £31 0s. 5d., and there was a balance in hand at the end of the year of £17.

The report was adopted by a unanimous vote.

The next business was the election of officers. Mr. Reginald Cory was reappointed president, Mr. J. Cheal chairman, Mr. J. P. Riding hon. secretary, and the other officers were also re-elected. Messrs. H. Stredwick and A. E. Vasey were appointed to two vacancies which existed on the Committee. The sum of £10 was voted as an honorarium to the hon. secretary in recognition of his services.

The date of the annual exhibition was fixed for Tuesday, September 10, to be held in conjunction with the Royal Horticultural Society's fortnightly meeting in the Drill Hall, Buckingham Gate, Westminster.

SCOTTISH NATIONAL UNION OF ALLOTMENT HOLDERS.

JANUARY 12. The first meeting of this Society was held at Glasgow on the 12th inst. Mr. James Scott presided over a good attendance of representatives from different parts of the country. Satisfactory accounts of the progress made since the preliminary meeting were given, but regret was felt that the Glasgow Federation had not affiliated with the Union. The draft constitution was submitted and agreed to with a few amendments. The following office bearers were appointed. President, Mr. John Hynd, Dunfermline; vice presidents, Councillor Mackenzie, Bo'ness, and Mr. Orr, Hamilton; secretary, Mr. Archibald W. Fisher, of J. L. Hill, M'Dougall and Co., Hill Street, Edinburgh; treasurer, Mr. J. M. Campbell, Falkirk.

BRITISH WHOLESALE FLORISTS

JANUARY 14. The first annual general meeting of the British Wholesale Florists' Federation was held at Essex Hall, Strand, on Monday, the 14th inst., Mr. Geo. Monro, junr., presiding. The report of the committee and statement of accounts were presented. The income for the year 1917 was £342 2s. 6d., representing ordinary income by subscriptions, £191 10s.; and donations to the promotion fund £150 12s. 6d. Current working expenses were £192 14s. 2d., and £139 16s. was spent on offices, furniture, advertisements, and other initial expenses. The president, in presenting the report, referred to to the death of Mr. Walter T. Ware, who was a generous supporter of the Federation from its institution in March, 1917. Mr. Monro pointed out that members had devoted over 50 per cent. of their open land, and much of their glass, to food production. Good work had been done in connection with the British bulb growing industry, the Corn Production Bill, railway transport, and vegetable seed production, and a system of recording the exact position of wholesalers and others connected with the flower trade had been instituted.

The report and financial statement were adopted; Mr. Geo. Monro junr., was re-elected president; Messrs. Geo. Cobley and Co., auditors; and the committee was re-elected with the addition of Mr. W. T. Mason and Mr. F. J. Forster, Covent Garden, to fill vacancies. The question of instituting a Florists' telegraph delivery scheme was discussed, and this raised a further point of extending the scope of the Federation so as to include the retail florists, and thus have one large, strong body representing the flower trade. The matter was referred to the committee for consideration, and report to a special general meeting, the general feeling being in favour of including the retailers. Mr. Monro expressed the hope that a Federal or Central Horticultural Council might be established.

SCOTTISH HORTICULTURAL.

JANUARY 15. The annual meeting of this association was held in the Gould Hall, 5, St Andrew Square, Edinburgh, on this date, Mr. J. Highgate, vice president, in the chair. The ordinary revenue account showed a deficit of £37 1s. 10d., and there was a decrease in capital of £16 19s. 3d. The Horticultural Institution Fund showed an increase of £68 4s. 5d. The Marquis of Linlithgow was re-elected honorary president; Mr. Robert Fife was elected president; Messrs. J. T. Chisholm, Edinburgh and East of Scotland College of Agriculture, and D. T. Johnston, Dalmeny Gardens, were elected vice-presidents. Seven councillors were elected in place of those retiring. The four small exhibitions which it was proposed to hold in conjunction with the monthly meetings in 1917 had to be abandoned, but prizes were awarded for the best allotments.

ROYAL CALEDONIAN HORTICULTURAL

JANUARY 9. The annual general meeting of this society was held in Dowell's Rooms, 13, George Street, Edinburgh, on this date, Mr. M. Hattie, vice president, in the chair. The accounts showed a balance of income over expenditure of £83 4s. 11d., and, after allowing for depreciation on investments, a decrease in capital of £90 5s. 1d. Lord Elphinstone was re-elected president, Mr. E. Dawson was elected vice-president, and Messrs. Thos. Smith, Stranraer, Wm. Muir, Linlithgow, and Geo. Anderson, Whittinghame Gardens, were elected to vacancies on the council.

CROPS AND STOCK ON THE HOME FARM.

How to Deal with Couch Grass.

THE hurried ploughing up and seeding with Oats of old Sainfoin leys last spring is, I fear, answerable for much land being badly infested with Couch grass. The adverse weather of last September delayed the harvest, which, in its turn, delayed until it was too late in the autumn any operations for the eradication of this pestilent weed.

The correct manner of dealing with a Couch crop in an Oat, Barley, or Wheat stubble, is to plough the land, but not too deeply, as soon as possible after harvest, thoroughly burying the surface grass. As soon as this grass decays, choose fine weather, and "run back," which means plough in the same furrow, thus exposing the original surface to sun, air, and wind. When the soil has lain long enough in that position to become dry, plough across the furrows, disintegrating the Couch as much as possible. With a continuance of dry weather use the drag often, to get the Couch on the top, collect it in heaps with chain harrows, and burn it as fast as possible. When the first batch of Couch has been cleared, plough again, repeating the dragging process and burning until the bulk of the weed has been cleared.

The months of April, May, and June are often favourable for cleansing land from Couch. For instance, a stubble ploughed in the autumn too late to do more at that season, will be in a good condition to tackle in March or April should the weather be dry. Plough sufficiently deep to move all the Couch, but no deeper, as a greater depth of soil would hamper the work of cleaning.

Repeat the process advised of dragging and burning in small heaps. Large fires are more satisfactory. This is, however, not permissible, owing to the order governing lights in the open at night. When one batch of Couch is cleared plough again; the oftener the land is ploughed the more thorough will be the cleansing process and the better the cultivation for the succeeding crop.

If the cleaning is done in June, Swedes may be sown, Turnips in July and early August, to be followed in spring with Oats or Barley. If Wheat is required in the particular field, sow with Mustard early in August, plough in this crop when about 2 feet high at the end of September or early in October, and sow with Wheat at once.

Or, instead of Swedes or Turnips, sow with Rape or Kale and feed these to sheep in October, plough at once, and sow with Wheat. Another plan may be adopted after cleansing the land if Wheat is required and no sheep available for clearing the Rape or Kale. Keep the land in summer fallow, repeatedly ploughing it, give a dressing of farmyard manure in September or October at the rate of 20 tons per acre, plough at once, pressing the soil if light in texture, and sow the Wheat forthwith. *E. Molyneux.*

Obituary.

ALEXANDER GRIGOR.—On Monday, 21st inst., there were laid to rest in Allenvale Cemetery, Aberdeen, the remains of Mr. Alexander Grigor, who for many years took a prominent part in horticulture in Aberdeen and the north of Scotland. He commenced his professional career in the service of Mr. John Gordon, of Craigmyle, and later was appointed gardener at Kincardine Lodge, Aberdeenshire, from whence he went to Fairfield, Aberdeen, where he was head gardener for the long period of 30 years. On the death of Mr. Gill, the proprietor of Fairfield, Mr. Grigor was appointed managing gardener at Duff House, Banff, where he had been for the past eight years. Mr. Grigor was a keen supporter of the Royal Horticultural Society of Aberdeen and the North of Scotland Horticultural Association. He was 72 years of age, and is survived by his widow, six sons, and three daughters. His eldest son, John, has been for many years gardener at Seapark House, Forres, whilst Richard is gardener at Dalswinton, Dumfries.

MARKETS.

REMARKS.—Chrysanthemums are gradually disappearing. The supply chiefly consists of spray white Heston, and prices remain firm. Home-grown Daffodils are increasing in quantity, and prices are lower. The varieties offered are Golden Spur, Emperor, and Princeps. The supply of Carnations is also increasing, and these flowers are offered at cheaper rates. Larger consignments from the Channel Islands are being received about three times weekly. Most consignments are arriving in good condition. White Narcissus Grand Primo are in most demand. A few boxes of Paper-white Narcissus from Scilly are soon bought at high prices. Other sorts coming to hand in larger quantities are single Daffodils and yellow Narcissus Soleil d'Or. A few boxes of Star of Bethlehem (Ahlum), Sweet Peas, and Freesia are also being received from Guernsey. A few blooms of Rose Richmond (new crop) are selling freely at high rates. Several boxes of Snowdrops reached the market to-day.

		Tomatos, English, per 12 lbs ...	15 0–18 0
		Walnuts, French, kiln dried, per bag	23 0–100 0

REMARKS. The bulk of English Apples consists of the following varieties: Bramley's Seedling, Duncelow's Seedling, Lane's Prince Albert, and Newton Wonder. The best grades are realising as much as 28s. per bushel. There are also weekly importations of French Russets, in cases from 60 to 70 lbs. weight. A fairly good supply of Grapes is reaching the market daily, both Gros Colman and Black Alicante. Almerias are also on offer. The following forced vegetables are now obtainable:—Asparagus, Seakale, new Potatos, Mushrooms, Peas, Cucumbers, Dwarf Beans, and Rhubarb. The chief Onions on offer are Spanish and French, very few English (if any) are offered. The market is fairly well supplied with ordinary vegetables for the season of the year. *E. H. R., Covent Garden Market, January 25, 1918.*

GARDENING APPOINTMENT.

MR J. TURK, for 31 years Gardener at Pontefract Lodge, near Hertford, as Gardener to ALBERT BARRETT, Esq., Totteridge Park, Totteridge.

ANSWERS TO CORRESPONDENTS.

APPLES TURNING SOFT AND ROTTEN: *J. C. D.* The two Apples have all the appearance of having been frozen. Some known to have been frozen have gone soft and rotten in precisely the same manner.

FIGS FOR MARKET: *Enquirer.* The varieties of Figs grown chiefly for market are Brown Turkey and White Marseilles as earlier varieties, and Negro Largo, Bourjassotte Grise, Bourjassotte Noire, and Rouge Noire as mid season and late sorts. The principal district where they are grown is Worthing and the surrounding neighbourhood. The style of house depends largely upon the system to be adopted, but as a rule span-roofed houses are best. It no forcing is contemplated it is not necessary to provide bottom heat. The best kind of house is the type used by Messrs. Rivers and Sons, Sawbridgeworth, for growing pot fruit trees. These are of simple construction, cheaply built, and durable, whilst the system of ventilation cannot well be surpassed, and you will do well to inspect these houses. It is a matter of choice whether the plants be grown in pots or planted out. If planted out it will be some three years before an average return may be expected, but from thence onwards the fruits may be larger than those grown in pots. Considerable information on the cultivation of Figs was given in our columns in the weekly notes on "Fruits Under Glass" last year. One essential of sending Figs to market is to gather and pack them whilst they are still firm, but well coloured. Careful packing is most important, and they travel best in what are termed "shallow handles."

MEALY BUG ON VINES: *Constant Reader.* Since you have tried most of the approved remedies you might try gas tar, as recommended by Mr. F. A. Edwards in our issue of October 25, 1913. He said: "On taking charge of the gardens here last autumn I found the Grapes quite white with mealy bug; they had to be washed before being sent to table. The vines were in a weak state, and had suffered badly from mildew. I cleaned off all the loose bark, especially round the spurs, and scrubbed the rods with a scrubbing brush, using a mixture of soft soap (2 ozs.) and sulphur (2 ozs.) in a gallon of water. The vinery was then well scrubbed with soft soap and water, and afterwards syringed with paraffin wherever it could be used with safety. The walls were whitewashed with hot lime, and the rods painted with the gas tar mixture, only the eyes and last season's wood being left. The tar was perfectly fresh, having been obtained from the gasworks only the day before. The mixture was put on in a stiff paste. The vines still look very blank, but the crops have suffered no harm. My employer told me a few days ago that they had not had such good Grapes for twenty years. I consider the gas-tar method both cheaper and safer than fumigation with cyanide of sodium."—*J. P.* In our issue for December 27, 1913, you will find a note on the subject by Mr. J. G. Blakey, Holmwood Gardens, Redditch, who has made a special study of destructive insects. For a description of how to fumigate with cyanide, see the issues for November 8, 1913, p. 184, April 26, 1913, p. 280, and February 17, 1912, p. 101.—*G. B. G.* See last part of reply to *J. P.*

NAMES OF PLANTS.—*Correspondents not answered in this issue are requested to be so good as to consult the following number.*

A. C. H. Psidium Cattleianum (Purple Guava).

ONIONS KEEPING BADLY: *H. B.* Probably your gardener is correct. Onions which are required for late use should not be given sulphate of ammonia or any other stimulating manure unless the ground is too poor to develop moderate-sized bulbs. The autumn of 1917 was not favourable to the ripening of Onions, and especially of late-sown plants. Onions grown on comparatively poor soil keep much better than those grown on ground of a rich nature. Deep cultivation is necessary, and any manure which is applied should be dug in at the time of trenching.

ONION SETS: *Herts.* You need not hesitate to plant the small Onions as sets. Select clean bulbs, remove the loose skins, and rub the bulbs with dry sulphur. Plant in an open part of the garden, and sprinkle the drills with soot previous to inserting the bulbs. If the ground is of a cold nature, a light dressing of dry lime may be applied before the surface is broken down.

RHODODENDRONS: *E. W. C.* Regarding the pruning of Rhododendrons, you need have no fear in doing what is necessary to keep the plants within bounds. That excellent variety, Pink Pearl, makes very straggling growth, and without pruning would become leggy and of unsightly appearance. Nearly every year some of the longest and barest shoots have to be cut back immediately after the plant has flowered. This causes growth to appear immediately below the cut, which helps to fill up the centre of the plant and make it bushy. This kind of pruning can be adopted in the case of any variety, but care must be taken that too many shoots are not taken from the same bush in one season, as this would adversely affect its flowering the following year. Hardy Heaths should also be pruned immediately after flowering. As a rule, they take kindly to pruning, and quickly make fresh growth; but we cannot give you detailed advice without knowing what sorts you grow, in what position they are growing, nor what height you wish them to be.

SHOT-HOLE FUNGUS: *W. G.* Shot-hole fungus, Cercospora circumcissa, attacks other stone fruits than Peaches. The disease may be arrested by spraying with the ammoniacal solution of copper carbonate at the time when the leaves are first expanding, and repeating the spraying at intervals. Bordeaux mixture should not be employed, as this specific is harmful to the leaves of Peach trees.

SUGAR BEET: *R. W. B.* There is no difficulty in growing this crop, but rich soil and an open position are necessary. Sow in drills made 2 feet apart and thin the seedlings to 1 foot apart in the row. Sugar Beet is not generally regarded as a garden crop, but it is listed by some seed firms, including Messrs. Ryders, St. Albans, who published a small pamphlet on the cultivation and uses of the plant.

TULIP SPECIES.

NO gardener who values his peace of mind should attempt to tackle the difficulties that underlie the nomenclature, the relationships, and the classification of the wild species of Tulip. Herbarium botanists have apparently given them up in despair, and this can hardly surprise anyone who has tried to find specific characters on which to base a sound classification of the various members of the genus. The present notes are intended rather to point out the inherent difficulties of the subject than to suggest solutions of them.

In the first place, the constituent parts of a Tulip are conspicuously few in number, and the opportunities for finding specific differences are correspondingly scanty. The bulb, the leaves, the stem, and the flower are practically all we have upon which to rely, for the capsules, and especially the seeds, of the different species are scarcely, if at all, distinguishable.

Let us first take the bulb, and, though there are differences, he would be a rash man who would undertake to sort out a number of species by their bulbs alone. Among other plants, for instance among Irises, it is easy to separate a number of species by their rootstocks alone, for no one could mistake the pink-fleshed rhizome of I. Pseudacorus or the green-skinned rhizome of I. Milesii for those of any other species. Among Tulips, the diagnosis is by no means so simple. It is easy, of course, to separate the bulbs of certain groups, such as Tulipa Greigii and T. Kaufmanniana, from those of such Balkan species as T. Hageri and T. Orphanidea, but to separate the bulbs of the several members of each group is practically impossible.

Stress is sometimes laid on the hairiness or smoothness of the inner surface of the outer skins of the bulbs, but though it is easy to distinguish such intensely woolly coats as those of T. praecox and T. montana, it will also be found that nearly every Tulip bulb produces some hairs on the inner side of its outer coat, even if the degree of hairiness varies among individuals of the same species. Some gardeners say that the bulbs, which have very woolly coats in the wild state, become less woolly under cultivation—a statement which does not agree with my experience, and of which more definite proof is required before it is accepted as a fact. At any rate, bulbs of T. praecox are still clothed in densely woolly coats after several years of cultivation in this garden.

Anyone who has cultivated a number of bulbs of Tulip species must be aware of the extraordinary extent to which the leaves may vary both in shape and size, as well as in number. This is certainly the case among stocks of collected bulbs, imported direct from Central Asia. Some leaves are pointed and some rounded, some long and narrow, others so short and broad as to be practically circular, and I do not think any close observer would venture to draw what he considered a typical leaf of T. Kaufmanniana, T. Greigii or T. Fosteriana. I remember seeing, on my last visit to Haarlem, a large bed of collected bulbs of T. Fosteriana in full bloom, and I was struck by the fact that some bulbs had very glaucous leaves, while in other cases the foliage was of a bright, vivid green. There were likewise variations in the flowers of these collected bulbs, but Mr. Hoog agreed with me that he was unable to couple any difference in the leaves with any variation in the flowers. It was therefore quite impossible to differentiate the plants into one or more sub-species. They were obviously all T. Fosteriana, but it would be extremely difficult to draw up an adequate diagnosis of this species.

The number of leaves produced by the bulbs of different individuals of the same species is apt to vary. I have never seen a flower stem produced when there was only a single leaf, but, on the contrary, it is extremely rare for a bulb, which produces two leaves on the same axis, not to flower, though it does sometimes happen that immature or young bulbs seem to exhaust their energies in the effort of producing a second leaf and a stem, and thus fail to develop the flower, of which, however, some rudiment is always apparently present. Some species, such as Hoogiana, and especially Schmidtii, produce quite a number of leaves, set close together rather high up on the stem, a fact which seems to indicate that the bulbs should be planted deeply, otherwise the plants are apt to be top-heavy and to snap off at the ground line. Botanists sometimes describe Tulips as having a definite number of leaves, but if they would carefully count those on a number of specimens, some strong bulbs and some weak, they would see, I think, that the number is never constant. For instance, T. sylvestris usually has three or four leaves, but a strong bulb produces five, while T. Sprengeri seems to flower equally well on stems that bear three, four, or five leaves.

Of the known species of Tulip, only Greigii and the nearly related Micheliana are supposed to have brown markings on the leaves. These are very vivid when the leaves first appear above ground, but soon fade to a greater or less extent, so that in herbarium specimens they may easily be absent altogether. Yet I have one bulb of T. Fosteriana, which I found by chance among a number sent from Haarlem to a neighbour's garden, which always produces leaves faintly but distinctly marked with longitudinal brown streaks.

Nothing could be simpler nor less characteristic than the ordinary Tulip stem. It is true that it may be quite smooth or minutely papillose or hairy, and that attempts have been made to separate species on this ground, but that this character is unreliable is shown, for instance, by T. praestans, in which the whole plant is usually covered with minute hairs, but of which occasional specimens are entirely smooth, though they differ in no other respect.

T. praestans is interesting in another way, and seems to afford evidence that there are in the wild state small local races of Tulips, most of which can be included under a specific name, and of which the outlying groups form connecting links between the species. It is apparently a fact that the original importation of bulbs to which the name praestans was given, contained nothing but specimens with bright red filaments to the anthers and flowers without any trace of basal blotch on the segments. About 1912 or 1913 Mr. Van Tubergen, wishing to get a further stock of bulbs of T. praestans, arranged with a collector to go to the identical district in which the species had been originally found, and very generously sent me specimens of the bulbs on their arrival. Curiously enough, every one of these proved to have black filaments to the anthers and a faint basal blotch of black, which fades entirely away when the flower has been open for a few days.

Colour is notoriously no safe guide to specific difference in flowers, and Tulips are no exception to the rule. One instance, that of T. praestans, has just been given, and it is only necessary to raise T. Kaufmanniana from seed to discover that the marking on the backs of the petals varies in almost every instance. They may be almost white, or pass through grey and pale blue to pink and deep red. Moreover, there are sometimes scarlet blotches near the base on the inner surface of the segments, which latter may be white in the upper part and yellow below, or wholly yellow, or even wholly bright scarlet. T. Greigii may apparently have a pure yellow base or a black base, or a base of any combination of patches of the two colours. The anthers, again, and the pollen may be yellow or purple-grey, or almost black, while the flowers themselves are usually scarlet, but not infrequently yellow blotched with scarlet.

Another puzzle for the herbarium botanist is provided by the Tulips of the Balkan group to which such names as Orphanidea, Hageri and boeotica have been given. Some of them are described by the authors of the names as having differences in the relative proportions of the filaments and anthers. On examining a number of flowers last April, I was inclined to think that some help in classification might be found in this character, but, having one morning carefully marked some plants that had long, narrow anthers, to distinguish them from others with short, broad anthers, I was astonished on returning to the plants in the afternoon to find that I had apparently made mistakes in attaching the labels. It was not until I had investigated matters very closely that I realised what had happened. Before the anthers burst, they were an inch or more in length and very narrow. On opening, however, they contract to less than half that length, and become twice as broad as they were at first. Dried specimens would therefore have to be very carefully examined in order to determine at what stage they were gathered and dried and whether the anthers had burst and contracted or were as long as they were when the flower first expanded. In any case, it is obvious that the relative length of the anthers and filaments is a very unreliable character on which to base specific differences.

It would be interesting to know if anyone can suggest any reason why some Tulips produce "droppers" or bulbs at a distance from the original bulb. Small seedlings of any kind of Tulip are very apt to do this, and some species never seem to grow out of the habit. T. Kaufmanniana is an inveterate offender, though some bulbs even of this species are content to produce an offset at the base of the mother bulb. The majority, however, produce one bulb where the bulb that has flowered was planted in the previous autumn and another at the end of a stolon-like growth, usually at a depth of several inches below the upper bulb. It might be argued *a priori* that the dropper went down until it came to more congenial soil, but here in this poor sand I find that the droppers go down through the layer of good soil and old manure, above which I endeavour to plant my Tulips, until they get into dry, hungry sand, which can hardly be to their liking. T. praecox has a curious habit of forming quite small offsets at some distance from the parent bulb, while the stolons sent out by T. saxatilis poke their noses into any hole in the rocky pocket in which I succeed in making this fine species flower annually, with the result that I rarely succeed in finding all the bulbs when I take them up. Sometimes in the case of this Tulip the stolons meet with a rocky surface, and then, because they cannot

go down or extend any further, they actually protrude above the surface. It was instances of this kind that showed me the end of the stolon thickening until it became a bulb without producing any roots. The nutriment is derived from the parent bulb and its leaves, and not from the soil in which the new bulb is formed, so that the roaming habit is not due to the attraction of a layer or pocket of rich food.

Another question to which it would be interesting to find the answer is, why do some species form no offsets, though the original bulbs are apparently quite vigorous and healthy, and grow on from year to year and flower annually? T. Greigii is a well known instance, and others are obtained an accurate idea of the various species that form the genus. The inquiry, though baffling, is undoubtedly attractive, and I shall be very grateful for any help from those who have special knowledge of the Tulips of any locality, or who possess specimens of undoubtedly wild Tulips, which are not easily obtainable. *W. R. Dykes, Charterhouse, Godalming.*

APPLE ST. CECILIA.

THE new dessert Apple St. Cecilia, illustrated in fig. 19, was raised from Cox's Orange Pippin crossed with an unknown variety. The seedling

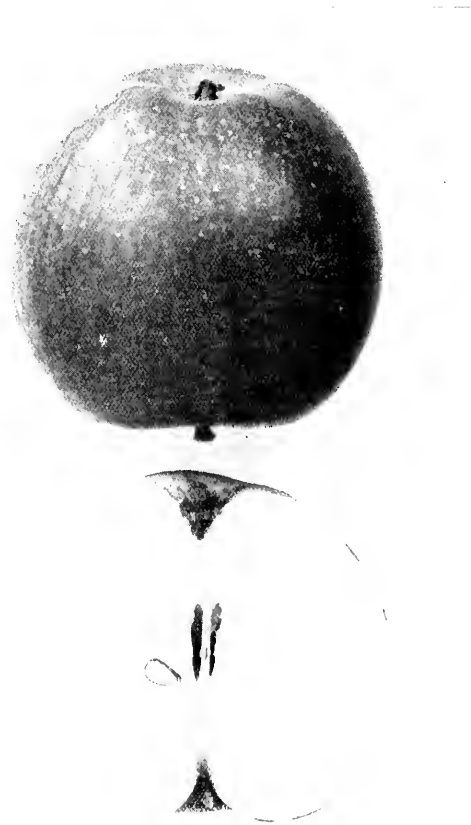

FIG. 19. NEW DESSERT APPLE ST. CECILIA
(R.H.S. Award of Merit, January 15, 1918.)

its relative T. Micheliana, and such species as ingens, Hoogiana and praestans. Fortunately, with the exception of Hoogiana, Micheliana and Eichleri, these wild species produce seeds fairly readily, though the ripening pods fall an easy prey to fungoid disease, and though the process of obtaining flowering bulbs from seeds is a lengthy one and takes at least five or six years.

It seems, then, as if a study of the habits of wild Tulips leads only to negative conclusions and to the conviction that little help can be obtained from dried herbarium specimens towards the determination of the limits of the distribution of each species; yet no real knowledge can be obtained of a genus of plants until we have

has much of the excellent quality of the Cox's Orange Pippin parent, and is a dessert Apple of first-rate quality, keeping longer than Cox's; fruits shown at the R.H.S. Exhibition on January 15, by Messrs. John Basham and Sons, were solid and juicy, without the least sign of shrivelling. To these qualities is added a strikingly handsome appearance, the fruits, though of small size, being as shapely as the best of Worcester Pearmain, and coloured a deep red all over, enhanced on the side next to the sun. The stalk is rather deeply set and somewhat slender. The illustration shows the fruits in their natural size. The variety will prove a valuable addition to late dessert Apples, and a successor to Cox's Orange Pippin.

FORESTRY.

THE HOME-GROWN TIMBER TRADE.

NEVER in the history of our country has the demand for home-grown timber been greater or prices higher than during the past twelve months. All kinds of timber have not, however, fared alike in that respect, the greatest demand being for Ash, Scots Pine and Spruce, and poles suitable for mining purposes. For the best cuts of Ash suitable for aeroplane construction the price has gone up by leaps and bounds, some logs being sold recently for 6s. per cubic foot where felled. In connection with this price it is well to remember that the high value is for picked trees, rough timber from the field and hedgerow being procurable in considerable quantity at from 2s. to 2s. 6d. per foot.

Scots Fir, which previous to the war could be bought in quantity at from 7d. to 10d. per foot, is now fetching 1s. 4d., and a plantation of very fine trees, averaging 40 feet each, was sold at fully one fourth higher than this price. Spruce is also in demand; it is scarcer than the Scots Fir, and has been sold of late at unheard-of prices, 1s. 4d. per foot being realised in the Metropolitan area for trees of 35 cube feet and upwards, where lying in the woodland. The pre-war price was about 7d. per foot.

Both Scots Fir and Spruce are particularly valuable for Government requirements, the timber being largely used in the making of ammunition cases and boxes of all kinds, as well as for trench work.

Other coniferous timbers, such as the Corsican and Weymouth Pine, Douglas and Common Silver Fir, have been sold of late at 10d. per foot, though in one instance at least 1s. 2d. was accepted for that of the Weymouth and Corsican Pines. Larch timber finds a ready market at prices which range from 1s. 2d. to 1s. 6d. per foot, but it is scarce when compared with the Scots or Spruce. It is the most useful of home grown coniferous woods, and is always in good demand. Elm has been much sought after of late, the price varying according to the district and quality from 1s. 2d. to fully 1s. 8d. per foot, but the price is curiously erratic even in the same county. For the best quality of Oak prices range high, 3s. 6d. per foot being paid for a large parcel of Surrey-grown trees. Welsh Oak, though not generally of large size, is of excellent quality and of a rich, deep colour, and the thinnings from a plantation in Denbighshire lately realised 2s. 6d. per foot in the woodland.

Beech has found a very remunerative market of late, and vast quantities of the timber have been felled in Buckinghamshire and Bedfordshire. That from the chalky Chiltern Hills is especially valuable, and sells at 1s. 4d. per foot in the wood. For Government purposes Beech timber is much in request. Birch and Alder suitable for clog soles and light furniture have advanced in price with the war, and about 10d. per foot may be considered an average value. Sycamore is in demand at all prices from 1s. 6d. to 2s. 6d. per foot, and some two hundred trees in Wales lately fetched 2s. 6d. per foot. For Poplar timber demand was never so great as at present nor prices higher, as much as 2s. 3d. per foot cube having been received for a number of trees some 50 miles from London. The usual selling price is, however, 1s. 4d. per foot where felled. Willow for artificial limbs and crutches, as well as other important purposes, is scarce, and remains but a short time on the market when offered for sale. Lime wood is being asked for at prices which average 1s. 4d. per foot, but it is scarce. Timber of the Lebanon Cedar, of which considerable quantities, chiefly wind-fallen, have of late been procurable, is being sold at a considerable advance in price over pre-war times. Some big logs, containing from 90 to 110 feet, were disposed

at recently at 1s. per foot. Owing to the official price being formerly 7d., and even so that "exchange" could not always find a market. Hornbeam is in demand, and from 7s. 6d. per stem 6 to 8 feet long has been realised; whole pieces 18 inches long by not less than 6 inches in diameter fetch 1s. each and upwards for skittles. Several of the less common and smaller growing timbers have found a ready market of late, particularly Holly, Elder, Acacia, Apple, Yew, and Evergreen Oak. For Holly, some of the sticks fully 15 inches in diameter, 2s. 6d. per cube foot was offered where they lay 3 miles from a railway station. Ten tons of Holly suitable for skewers was lately offered, and a truck load 5 inches to 12 inches diameter at 4s. 6d. per foot net. Wood of the Gean or Wild Cherry is selling well, and nearly a hundred trees in Kent, averaging 25 feet each, fetched 1s. 6d. where they were felled. Walnut in small quantities has been offered of late, and for some seasoned logs 4s. 6d. per foot was obtained. It is useful in many ways, and for gun and rifle stocks has no equal, as, apart from quality and beauty of graining, the timber does not rust metal with which it comes in contact. Of late, timber of the Sweet or Spanish Chestnut has been finding a better market than probably ever before, good, sound logs bringing 1s. 3d. per cubic foot—quite 6d. more than the average of three years ago.

Firewood is scarce and dear, a cord of Beech or Oak being, roughly speaking, one fourth higher in price than was the case before the war, while faggots for fire lighting have also advanced fully 25 per cent. Charcoal for heating the trenches in France and Flanders is much in demand at advanced prices, while timber suitable for charcoal for gunpowder making finds a ready and remunerative market.

The maximum prices for home grown timber fixed by the Controller of Timber Supplies will go far in regulating the output and value of native wood. *A. D. W.*

THE ROSARY.

ROSES OF CALIFORNIA AND NEVADA.

A RECENT issue of the *Bulletin of the Torrey Botanical Club* contains a paper on the Roses of California and Nevada, by Mr. P. A. Rydberg, who is monographing the American species for the *North American Flora*. Thirty four species are admitted for the area in question, one, however, being the Sweet Briar, the only member of the Canina, which is found as an escape from cultivation. The indigenous species are arranged in three sections: Cinnamomea with 29, Muntifoliae with one, and Gymnocarpae with three. No fewer than twelve species are described as new. An analytical key is given, with details of localities and collectors. Four of the species are in cultivation in Europe, namely, Rosa nutkana, R. californica, R. pisocarpa, and R. gymnocarpa.—*B. H. R.*

TREES AND SHRUBS.

ECCREMOCARPUS SCABER.

AMONG the many plants remarked on recently as having withstood the severe weather of last winter, I noticed no reference to Eccremocarpus scaber. This plant is growing here on the south east side of a dwelling among a medley of Jasmine growths, through which it has clambered up and over, looking very pretty with its scarlet and gold tubular flowers. The species did not survive the winter with me at Highgate, but it came through last winter here unharmed. No doubt the roots and top growths of the Jasmine afforded the plant protection, while the soil is light and on the dry side.—*C. T., Ampthill Park Gardens, Bedfordshire.*

THE GENUS COCOS.

WHEN writing some notes on "Garden Palms in the *Gardeners' Chronicle*" 33 years ago I stated, under "Cocos," that of the thirty or so species then known about twenty were in cultivation at Kew and elsewhere, and that they showed a much wider range of variation than any other genus of Palms. The differences in habit and leaf-structure between C. nucifera, C. plumosa and C. Weddelliana, for example, are very striking. With regard to C. nucifera, the Cocoa Nut, there is the remarkable fact of its being found wild in most tropical countries, and that its origin is obscure. De Candolle, in *Origin of Cultivated Plants*, inclines to the idea of an origin in the Indian Archipelago, whence it had been distributed to other countries ages ago by ocean currents. It is essentially a seaside tree, rarely, if ever, thriving away from the coast. All the other species are natives of tropical America. Dr. O. Beccari, in a revision of the genus Cocos, has reduced it to a single species, namely, C. nucifera, the others being regarded by him as members of other genera. A list of these, in accordance with Beccari's revision, is published in the Kew *Bulletin*, Nos. 9 and 10, 1917, the cultivated species being renamed as follows: C. Arechavaletana Arecastrum Romanzoffianum; C. australis Butia capitata; C. Bonnetii Butia Bonnetii; C. campestris Syagrus campestris; C. capitata Butia capitata; C. comosa Syagrus comosa; C. coronata Syagrus coronata; C. Datil Arecastrum Romanzoffianum; C. elegantissima Syagrus Weddelliana; C. eriospatha Butia eriospatha; C. flexuosa Arecastrum Romanzoffianum; C. insignis Syagrus insignis; C. longifolia Attalea excelsa; C. mammillaris Butia Yatay; C. Normanbyi—Normanbya Muelleri; C. nucifera the Cocoa Nut; C. pernambucana Syagrus botryophora; C. plumosa Arecastrum Romanzoffianum; C. Procopiana Syagrus macrocarpa; C. Romanzoffiana Arecastrum Romanzoffianum; C. schizophylla Butia Bonnetii; C. Weddelliana Syagrus Weddelliana; C. Yatay Butia Yatay.

The following do not appear to have been dealt with in this revision: C. amara, C. Blumenavii, C. botryophora, C. Butuei, C. Gaertneri, C. Mikaniana, C. Marie Rose, C. Sancona, C. Yurumaguas.

It will be seen that plumosa, one of our most popular Palms, has the misfortune to be re-christened with a name that has little chance of ever being taken up by gardeners, also that flexuosa, Datil and Arechavaletana are identical with it. The popular little Cocos Weddelliana is now a Syagrus, as also is another similar little Brazilian Palm formerly called Glaziova insignis, now to be known as Syagrus insignis. Butia is not a happy generic title, as it too closely resembles Butea, a genus of Leguminosae, of which B. frondosa is a showy Indian tree with valuable economic properties. Anyhow, it is satisfactory to have the Cocoa Nut set out as a distinct monotypic genus, seeing that in its way it is as singular as the Double Cocoa Nut, Lodoicea sechellarum, and that it is by far the most valuable of all tropical trees.—*W. W.*

FIG. 20.—A POT SPECIMEN OF THE COCOANUT PALM, COCOS NUCIFERA.

WALL FRUIT TREES.

DESIGN, PLANTING, TRAINING.

AN enormous number of wall trained trees are too large, massive, and irregular in form to bear evenly and regularly. The average fruit tree of any shape or size carries enough wood to make a dozen. The form and substance of a tree determines its capacity for bearing. Large and shapely trees, whilst attractive to the eye, are too long in coming into profit, are the most difficult to deal with and are never entirely under control. Soil, climate, situation, space available, type of tree, domestic needs, and personal capacity or inclination, have to be considered, but the prime necessity is a tree that will mature early and bear regularly.

If we allow that the world moves ever so slowly, and that waste is inexcusable, the big and complicated forms of espalier, fan shaped, and less definite wall trained trees should be regarded as obsolete; at least, they are not desirable for Pears or Apples, and in passing one may say that the Apple has not yet come to share the wall space it merits.

Single Cordons are the simplest, surest, and most profitable of all known or conceivable forms of fruit trees for walls, and should predominate everywhere. The more one understands the nature of fruiting trees, it will be apparent that but little wood is wanted, and with fewer branches the pruning grows less, simply because little or no excessive growth is allowed to occur. If a tree is planted well above the surrounding land, as a maiden, or by pruning is made light in structure, given an inclination of about 45° or a few points less for the first two or three years—and no more than finger-pinched till the desired height and number of spurs are obtained, it will not be able to develop an over-robust root system, nor to make a trunk or lateral growth too coarse or imperfect to yield good fruit freely.

Wall trees—and all others if they are to be under control—should have shallow and light root systems, and any risk of drought should be met by mulching. The mulch is of especial value, as where a soil is well drained and freely aerated the mulch promotes and preserves the finest type of fibrous roots, thus promoting and supporting fruit. It may be said with emphasis that no Cordon Pear or Apple tree needs more than a barrowful of soil, provided such soil is composed of suitable materials placed on a cool but drained base, and receives a sweet, nourishing mulch during times of much heat and cold.

We do not improve much in forming and managing trees, and though there are good books on the subject, the vast majority of men cut blindly and train and trim without reason.

A Pear rod an inch or so in diameter at its base, and tapering like a whipstock, will support sufficiently vigorous fruit spurs over thirty to fifty years. A similar rod of the average Apple will not prove profitable over more than half that length of time, or, say, fifteen to twenty five years. But in either case it is long enough, for we should not strive to make true the jingle and absurdity of planting Pears for our heirs—or even Apples.

The stock—as dwarfing or free is a pronounced factor in the wood growth of Pears and Apples, but it is necessary to limit the soil supply and the root range that the head growth may be limited, light, and always well ripened.

A Cordon tree should be widest at its base, the lower spurs complex or multiple, fairly stout, and spreading 6 to 9 inches on either side of the stem. It is always necessary to have heavily built spurs at the lowest parts, or the super-growth will overwhelm and exhaust them. The spurs should be shorter, lighter, and further apart as they ascend, then the sap will be evenly apportioned, and every part of the tree bear fruits of even size and quality.

Cordons will form trees from 10 to 12 feet high if planted 3 to 4 feet apart. It is not wise to plant them closer, as where very close planting occurs the roots interfere with each other, and there is insufficient space, light, air, and sunheat for leaf development.

The borders in which wall fruit trees are planted should always be raised several inches above the ground level, and cut off by such means, and by good drains, from any soakage of water from adjacent land.

Neither leaf mould nor strong dung should be incorporated with soil intended for fruit trees, but lime, mortar-rubble, wood ashes, sand, or any clean, gritty matter, with a spadeful or two of fibrous soil about the roots at planting, are valuable additions.

If the soil of a border or extended space to carry Cordons is heavy, uneven in form and quality, or infested with weeds, the whole mass should be thrown out to leave an open trench from early winter till February or March. This treatment will clean and improve the soil, show what draining, if any, is needed, and secure a true foundation at a uniform depth for all the materials required by the roots.

Drains should never be placed under the planting lines, and in the case of wall trees they should run not less than 3 feet from the walls. Excepting unusually heavy soils, or where much water drains towards the wall, a border may be so raised and composed as to obviate draining.

After forming a border planting should be deferred for two or three weeks to allow the soil to settle to its former level. Unless trees can be set out in the early autumn it is better to nurse and protect them through the winter and plant in March or early in April. A tree is aided by cutting or preparing its roots in autumn, as then a callus is formed by the spring. A tree does best planted when it may move in the roots but not in the head, for root growth should always precede head growth in a newly-planted tree.

No tree was ever planted too high. The best examples of high planting are the millions of fine trees on the raised banks of British hedge rows.

It is true that Pears on Quince stocks should be planted to cover the union of stock and scion, but it is sometimes safer to apply a thick bandage and to keep it on indefinitely.

Cordon trees should be inclined away from the strongest light, otherwise they will grow thick at the top and bare at the bottom. The angle or slope of a tree should be according to its native vigour. The stronger the tree the more it should be trained from the upright line. Therefore, if several sorts of Pear or Apple are chosen for Cordons, their habits and needs should be known, for it neither looks well nor pays to have trees running at different angles on one stretch of wall.

Trees should not be planted within a foot or 15 inches of walls. The jamming of trees against walls is a common cause of disease, irregular growth, and unprofitable results. For Cordons a stake or smooth rod should be pressed in a foot or two to one side of the planting site, and at planting the tree should be leaned over and tied so that its roots are kept steady and the head prevented from chafing by the wall. A thick bandage should be placed round the stem and the stake to prevent rubbing and cutting of the bark. The stake or pole will serve for the first two or three years, according to the length of the Cordon at planting, after which time fairly long pegs should be driven into the wall at intervals of 3 feet or so and the tree drawn over and inwards and secured, so that it slants towards the top of the wall. There should be no forcing or bending or close nailing in of the main stem, nor is there any advantage in nailing any other growth to the wall. *A. C.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

TOMATOS.—In raising seedling Tomatos aim at securing dwarf, healthy plants that will produce their first cluster of fruit 12 or 15 inches from the soil in the pots. If the plants come up thickly in the seed-pan thin them early, and shift them singly into small pots when they are of a suitable size, and continue to grow them in the same house. The soil for potting should be light in texture and warmed to the temperature of the house. Grow the plants on shelves near the roof-glass, and water them carefully with warm water. Pot the plants before they become pot-bound, for neglect in this matter would cause them to grow spindly, especially if the first pots are of small size.

FORCING PITS.—Where the fermenting material was prepared as advised in a previous calendar it will now be ready for making into hot-beds for the forcing of early Potatos. Pack the material firmly together and cover it with about 1 foot deep of rich, light soil. As soon as this is warmed through, plant the Potatos previously sprouted in boxes, making the rows 15 inches apart and putting the sets 10 inches apart in the rows.

FORCING.—Continue to insert fresh batches of Asparagus, Rhubarb, and Seakale in heat, selecting strong roots or crowns. Let the clumps be well moistened with tepid water and weak liquid manure to hasten the forcing. If plants of Seakale in the open have not been covered, these should be attended to. First clear the ground of weeds and then lightly fork the surface. Cover the crowns with a heap of fine coal ashes. Place Seakale pots over a portion of the plants, and surround them with sweet fermenting material composed of leaves, or leaves mixed with stable litter, sufficient to create a gentle warmth, and to exclude the cold air. The remainder of the bed should have the crowns well covered with ashes, placing a ridge of soil over the ashes, which will ensure a much later and equally satisfactory crop.

SHALLOTS.—The bulbs should be planted at the first opportunity in an open situation on well-prepared ground. Allow a space of 12 inches between the rows, and not less than 6 inches between the bulbs, giving the larger growing varieties a little more room than the smaller sorts. Bury the bulbs rather more than half their depth. The ordinary English variety is one of the best for general use; the large red-skinned varieties give larger bulbs.

PEA AND BEAN STICKS.—Get together a supply of Pea sticks, sharpen the points and tie them in bundles of the same size. Stakes for Runner Beans should also be got ready in the same manner. Doing work of this kind now will ease matters when the busy season arrives.

ARREARS OF WORK.—The work of digging and trenching has been delayed by the recent severe weather, and with a depleted staff this will mean disorganisation in the spring, unless special efforts are made to overtake arrears. Pay attention to early borders first, adding leaf mould and any other light compost available, as there is a scarcity of animal manure. To secure good crops, all soil should be moved deeply more or less, according to circumstances.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

STRAWBERRIES.—Where new Strawberry beds were made last season it will be well to take the first opportunity, when the soil is fairly dry, of treading around the plants to make them firm after the frosts. Having done this let the ground be lightly hoed. Older plantations should have the soil lightly forked up around each crown and between the rows, or if this were done in the late autumn the ground should be merely hoed. In the case of plants growing on heavy soils, or those in old beds, apply a light dressing of well-rotted manure, spreading it on the surface and allowing it to remain there for the present.

AUTUMN (OR PERPETUAL-FRUITING) STRAWBERRIES.—I prefer to plant autumn-fruiting Strawberries early in the spring rather than in late summer. When new beds are required—and it is better to form these in alternate years the site should now be chosen, in a warm sunny situation. Let the ground be trenched two spits deep, provided deep digging does not interfere with the roots of fruit trees. Use farmyard manure if obtainable, and ground lime; place the manure in the second spit. Select the best possible runners from the old beds, lifting the roots with a ball of soil. Set three plants in a group at about 6 inches apart, allowing a space of 2 feet between each group, and the same distance between the rows. Plant when the ground is in good working condition, and make the soil firm afterwards. My reason for advocating spring planting is to ensure a good growth before the autumn flower trusses appear. These Strawberries have a tendency to develop a plentiful supply of late flower trusses, and do not, in consequence, make such good plants when planted late. The following is a list of proved varieties: St. Antoine de Padoue, St. Fiacre, Continuity, Merveille de France and La Perle.

WINTER WASHES.—Advantage should be taken of fine, still days to apply a winter wash to fruit trees. I do not advise the use of concentrated alkali washes too frequently, for it has a tendency to harden the bark of Apple trees. If used two seasons in succession it should be missed on the third, and a mixed winter wash used instead. Where, during the past spring, there were attacks of Caterpillars, I advise that the mixed wash be used in good time, the spraying to be repeated, if necessary, later. Be careful not to exceed the strength recommended by the makers; certain specifics can be used at an increased strength in the dormant season. It is well for the operator to wear indiarubber gloves and a mackintosh as a safeguard against injury to the hands or to the clothes. Where American Blight is a source of trouble strong measures must be resorted to, and where the trees can be effectually treated by hand I advise the use of a

strong mixture of paraffin and soap applied with a stiff paint brush. The pest is often present in the soil on the roots of the trees, and it may be attacked there with a sterilizer, of which there are several on the market. Lime sulphur spray is the most effectual specific in many instances. Trees of Cox's Orange Pippin Apple in these gardens are sometimes affected with mildew, and lime sulphur is an excellent remedy for mildew. Use this wash first when growth is dormant, and again later if necessary. It will also destroy red spider; indeed, lime sulphur is a most valuable preparation generally for the fruit grower.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

CHERRIES.—Cherry trees growing in borders may be allowed to start into growth with little or no fire-heat. A little artificial warmth may be used at night during the flowering period, but only sufficient to maintain a dry atmosphere. By these means a succession of fruits to those from pot trees may be maintained. The house should be cleansed thoroughly, and the trees washed with a suitable insecticide. A house is not usually devoted entirely to Cherries. Cordon trees do exceedingly well trained up the front of mid-season and late Peach houses, where very little fire heat is required. The following are suitable varieties for the purpose: Werder's Early Black, Governor Wood, Early Rivers, Elton, Frogmore, Early Bigarreau, Bigarreau de Schrecken and Downton. Standard fan trained trees do equally well on the back walls of fruit houses, if cool conditions can be maintained. All varieties may be grown in the orchard house, and in these unheated structures a succession may be obtained by planting Florence Bigarreau, Napoleon, Géant d'Hedelfingen, and Late Duke. Autumn planting is always preferable. A moderately light, rich loam should form the bulk of the compost used for the border, with a suitable proportion of mortar rubble, burnt garden refuse, and decayed leaf mould. In restricted borders the roots are well under the control of the cultivator.

EARLY VINERY.—When the shoots of early vines are sufficiently advanced for training they should be brought down to the wires by degrees, according to their stiffness; if bent much at first they will snap at the base. As the shoots advance sufficiently to be thinned, retain the strongest or best situated, with the most promising bunch. If the spurs are regular, one shoot will be sufficient; the others should be removed. An extra shoot on a spur is not injurious to the vine, but space is necessary for the fruit to develop. Daily attention must be given to stopping the shoots, usually two leaves beyond the bunches. A night temperature of 60° should be maintained, but a rise of 10° or 15° will do no harm. Regulate the amount of damping according to the state of the weather, only lightly sprinkling the floors and bare spaces on wet, dull days. Admit air every day more or less, but do not permit cold draughts to reach the vines. Coarse tiffany stretched over the ventilators will prevent cold, gusty winds from reaching the tender foliage.

STRAWBERRIES.—Successional batches of pot Strawberries may be placed on shelves in Peach houses that have just been started. In our damp, cold district, I find it much the best to winter the plants in cold frames. Before the plants are brought into the glasshouse the pots are placed on their sides and the foliage thoroughly syringed with an insecticide. A little of the surface soil is removed and replaced with a rich compost. Great care must be exercised in watering, as very little moisture is required until the roots are active. Reserve plants in cold frames must not be allowed to suffer for want of water.

POT FRUITS.—Provided there is sufficient space, a few early varieties of Plum and Cherry trees in pots may be placed in Peach houses that have just been started. Syringe the trees with an insecticide or fumigate them in the house. The roots will not need much water until top growth commences. Syringe the trees once or twice daily, and do not let the temperature rise too high or the atmosphere become excessively close.

PLANTS UNDER GLASS.

By F. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CLERODENDRON FALLAX.—If cuttings of Clerodendron fallax are available they may be inserted singly in small pots filled with a light, sandy compost. Let them be sprayed two or three times daily in bright weather and shade them from sunshine until roots are formed. This plant may also be raised now from seeds sown singly in 3-inch pots and plunged in a hot-bed. Cover the pots with a sheet of glass, and shade them till the plants are through the soil. Red spider often attacks the leaves, and may be kept in check by syringing the foliage regularly with rain water.

CALADIUM.—Batches of Caladiums may be placed in their growing quarters as required. In large specimens are desired several bulbs may be placed in each pot, those of 5 or 6 inches in diameter being suitable. Later the plants will need more root-room, and bigger pots will be required. A fairly rich compost should be employed, as the Caladium is a gross feeder when in active growth. When potted, place the plants in a house having a moderately warm temperature and water them with extra care until they are well rooted. When the plants are growing freely, close the house early in the afternoons after spraying them with rain-water.

FREESIA.—The main batch of Freesias should be kept growing in cool conditions. If necessary, a few may be hastened into flower in a warmer house. Let the roots have plenty of stimulant as the flower stems will grow weak. See that the stems are neatly and sufficiently supported with stakes.

LACHENALIA.—This useful greenhouse plant will soon be throwing up flowers, but unless bulbs are required early the plants must not be forced unduly. A shelf near the roof-glass in the greenhouse is an ideal position for Lachenalia until they flower. When the pots are full of roots the latter should be given diluted liquid manure and soot water alternately.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

SOPHRONITIS GRANDIFLORA is in bloom; the flowers are produced from the partly developed pseudo-bulbs, and should be kept sufficiently moist at the roots to keep the Sphagnum moss green and healthy. Care must be taken that water does not lodge in the centre of the young growths, as this might cause the young pseudo-bulbs to decay. Plants requiring fresh rooting materials should be attended to when roots begin to develop from the new shoots. This Orchid is best grown in well-drained, shallow pans, using a very thin layer of Osmunda fibre and Sphagnum moss for a rooting medium. Suspend the pans from the roof rafters, in a cool house.

PLATYCLINIS GLUMACEA.—This useful species has commenced pushing up its new growths, and may be repotted at any time between the fading of the flowers and the ripening of the young pseudo-bulbs. Well-drained shallow pans, that may be suspended from the roof, form the best receptacles. The plants need plenty of water at the roots all through the growing season, and should be grown in an intermediate temperature. The rooting medium may consist of two-thirds A 1 or Osmunda-fibre, one-third good fibrous loam with the small particles removed, adding some chopped Sphagnum-moss, and crushed crocks to render the soil porous.

MEXICAN LAELIAS.—Plants of Laelia albida, L. autumnalis, L. Gouldiana, L. furfuracea, and those of the Laelia anceps type, should be afforded very little water at the roots after they have finished flowering, it being only necessary to keep the pseudo-bulbs from shrivelling. If fresh rooting material is necessary it should be afforded as soon as roots develop from the bases of the new pseudo-bulbs. Well-established specimens growing in receptacles sufficiently large for their needs should not be disturbed unnecessarily, but where the old compost has become loose and decayed it should be carefully removed with a pointed stick, and all the small particles washed from among the drainage, afterwards adding fresh rooting material. Plants that have overgrown their receptacles may, if there are numerous pseudo-bulbs behind the leading growth, be divided and made again into shapely specimens. Whether the pieces are potted up separately, or several together, it is not necessary to retain more than two or three pseudo-bulbs behind each leading growth. Shallow pans or Teak wood baskets may be employed for these Mexican Orchids, and they should be of sufficient size for at least two seasons' growth. In re-potting, keep the rhizome of the plant just on a level with the top of the receptacle, which should be about half filled with clean crocks for drainage. A suitable compost consists of equal parts of coarse Osmunda and A1 fibre, with all the dust removed. In re-potting, press the compost firmly, especially along the rhizome of the plants, and insert a few pieces of crock in the compost to assist the free passage of water. Grow the plants in a house having an intermediate temperature, standing them in a light position near the roof glass.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

PROPAGATING. Cuttings of by far the greater number of flowering plants used in garden decoration root best in warmth in a very moist atmosphere at this season, and no material is better adapted for rapid and certain root production than moderately coarse sand, and sea sand is suitable. Cuttings should all be in a growing state when taken, and, in opposition to the generally received opinion, the cuttings of nearly all kinds of flowers produce roots without cutting the slips across below a leaf node. All that is needed is to cut them off the stock plants above a leaf, when they will be in a proper condition to insert in the rooting material. It is very important that the cuttings should not flag, and when many are taken at a time they should be thrown into water till ready for insertion. The sand bed should be soaked with tepid water a few hours previously to inserting the cuttings, thus ensuring that the sand is neither too wet nor too dry. There are two rapid methods of insertion. One consists in making a depression of the correct depth and width with a narrow sheet of glass by pressing it into the sand. The cuttings are then rapidly arranged in the slit, and they may be touching each other if need be where space is limited. After the slit is filled the sand is pressed against the cuttings and another depression made parallel to the first, and so on, till all are inserted. The other method is more suitable for large slips. Each one is grasped between the finger and thumb, the index finger lying along the cutting, and with it is pressed into the sand. It is almost as rapid a proceeding as the first named. Where cuttings are rooted in boxes a very sandy compost should be used, and I find that girls do the work more rapidly and effectively by making holes for the cuttings across the lines, then dropping a cutting into each hole and pressing a section down. Either glass or paper should be placed over the cuttings till the latter are rooted; sometimes both are necessary when the sun is strong. There are a few plants which do not succeed when treated as above; Ice plants for instance, and especially the variegated Ice plant. The cuttings of this plant need no "making" after removal from the plants, and are inserted in boxes like the others, but they should not be watered till roots have formed. These need no bottom heat. Pelargoniums form another class which demands special treatment. These I always cut under the leaf, though they root sometimes away from one, but the usual method is the safest. Varieties vary considerably in the way roots are produced; of some a percentage is always lost, whilst of others, as Paul Crampel and the Ivy leaf varieties, every one roots. All root with least loss when inserted singly in small pots filled with a sandy compost. Water with extra care until calluses have formed. A high temperature is to be preferred, and for the first few days, should the sun be powerful enough to affect the leaves, a slight shading, such as newspapers afford, should be spread over them.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

APPOINTMENTS FOR FEBRUARY.

MONDAY, FEBRUARY 4—
National Chrysanthemum Soc. Ann. Meet. at Carr's Restaurant, Strand, 6 p.m.

TUESDAY, FEBRUARY 5—
Scottish Hort. Assoc. meet.

THURSDAY, FEBRUARY 7—
Manchester and North of England Orchid Soc. meet.

FRIDAY, FEBRUARY 8 —
Royal Gardeners' Orphan Fund Annual Meeting and Election of Candidates, at Simpson's, Strand, 3 p.m.

TUESDAY, FEBRUARY 12—
Roy. Hort. Soc.'s Comm. meet.

THURSDAY, FEBRUARY 21—
Manchester and North of England Orchid Soc. meet.

TUESDAY, FEBRUARY 26—
Roy. Hort. Soc.'s Comm. meet.

WEDNESDAY, FEBRUARY 27
Elgin Hort. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.5.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, January 31 10 a.m., Bar. 30.2, temp. 41.5°. Weather—Foggy.

Mildew Resistant Hops.

The Hop growers of England have two pests with which to contend: "mould" or "red mould," caused by the mildew fungus Sphaerotheca Humuli; and the blight caused by the insect Phorodon Humuli. The latter, if treated with a suitable insecticide, does not cause the grower very great anxiety, but the mould, if it makes its appearance in dull, damp seasons, may, in spite of assidnous sulphuring, cause very serious losses. Mr. Salmon, whose most recent investigations* we now describe, estimates that the ravages of red mould in 1916 cost the growers many thousands of pounds, for many acres had to be left unpicked and the less severely affected Hops suffered a serious reduction in price. The species of fungus which attacks the Hop, Humulus Lupulus, also attacks the other genera of the Hop family; but it has been shown that the fungus (Sphaerotheca Humuli) is, like other species of mildew, a specialiser: it develops biologic forms which concentrate their attention each on a separate host, and, as a defect of this quality of specialisation, become less apt to attack any other species of plant.

This being so, it should not perhaps prove impossible to discover a variety of Hop which the highly specialised mildew might be unfitted to attack; in short, to discover mould-resistant Hops. The possibility of the existence of such resistant forms was converted to a certainty by observations made by Mr. Salmon in 1914. In that year seedling Hops were raised and grown under glass in large numbers for experimental purposes which required them to be cultivated under conditions favourable to the development of mildew. So favourable indeed were the conditions that, generally speaking, it only required a Hop plant to be brought into the house for it to be attacked. Nevertheless, among the seedlings two plants failed to contract the disease. In spite of their surroundings, and in spite of efforts made to infect them, these two plants remained immune. They were seedlings of the "wild Hop," obtained from Italy. Other seedlings of the same origin, some 70 in number, proved susceptible.

In 1916 a precisely similar observation was made—seven seedlings of the "wild Hop," out of a total of about 160, proved resistant to mildew.

Another resister also appeared in the form of a yellow-leaved Humulus Lupulus obtained from Messrs. Bide and Sons, of Farnham. This golden Hop resisted all efforts to induce it to take mildew.

The immune seedlings of 1914 were planted out and grown on at Wye. One proved to be a male, and the other a female. In the bad mildew year of 1916 they retained their immunity throughout the summer and early autumn, but mildew appeared in October on both seedlings.

From these facts it is reasonable to conclude that varieties of Hop may be found which possess complete immunity with respect to Hop mildew, and from analogy with what has been done in the way of breeding forms of plants resistant to other diseases (rust of Wheat, wilt of Cotton, etc.), it is probable that mould-resistant races of Hop may yet be raised, to the comfort of the Kentish men and the profit of British agriculture.

In connection with the subject of immunity, Mr. Salmon draws attention to the following interesting fact concerning the Virginia Creeper (Vitis hederacea). This plant when growing in the United States is commonly attacked by a mildew (Uncinula necator), but no record is known to Mr. Salmon of this fungus attacking Virginia Creepers growing in this country. He suggests that this is not a case of immunity, but that freedom from attack here is due to the absence of the biologic form of the fungus which makes a speciality of, and alone possesses the secrets of success in, attacking the Virginia Creeper. In support of this view, Mr. Salmon points out that a precisely similar state of affairs obtains with respect to the Hop in Japan. There the Hop is never attacked by mould, but specimens of Japanese Hops raised in this country prove to be completely susceptible.

Mr. Salmon does well to warn us that trouble may be in store if we once allow of the introduction into this country of American-grown Virginia Creepers. They will of a certainty bring the mildew with them, and once arrived here it may make itself painfully at home.

* *On Forms of the Hop Resistant to Mildew*, by E. S. Salmon, S.E. Agric. College, Wye.

ROYAL GARDENERS' ORPHAN FUND.—The annual general meeting of the Royal Gardeners' Orphan Fund will be held at Simpson's Restaurant, 100, Strand, London, W.C., on Friday, the 8th inst., for the purpose of receiving the report of the committee and statement of accounts for the past year; to elect officers for the ensuing year; to elect by resolution fourteen children to the benefits of the Fund; and to transact such other business as may arise. The chair will be taken at three p.m.

DENMARK PROHIBITS TRADE IN SEEDS.—According to the *Board of Trade Journal* H.M. Minister at Copenhagen reports that the Danish Ministry of the Interior has issued a notice forbidding, pending the issue of further regulations, trade in all kinds of seeds, including field seeds, root seeds, and garden seeds, whether of Danish or foreign origin, both of the 1917 and of previous harvests. Moreover, all deliveries of such seeds, notwithstanding running contracts, are forbidden until further notice. Bird-seed is, however, excepted.

LECTURE ON POTATO-GROWING.—The President and Council of the Royal Horticultural Society have arranged for a lecture to be delivered at the Mansion House, at 3 p.m., on Wednesday, February 13. The subject of the lecture is "Potato Growing—Spring Work in Seed and Planting," and the lecturer is Mr. W. CUTHBERTSON, J.P., V.M.H. Admission will be by ticket only, which can be obtained from the Secretary of the Royal Horticultural Society, Vincent Square, Westminster, on written application accompanied by a stamped addressed envelope.

THE NATIONAL CHRYSANTHEMUM SOCIETY.—The meetings of the Executive Committee of the National Chrysanthemum Society will be held on February 18, September 23, October 21, November 18, and December 2, at Carr's restaurant, Strand. The Floral Committee will meet at Essex Hall, Essex Street, Strand, at 3 p.m., on September 23, October 21, and November 18, and at the London Scottish Drill Hall, Buckingham Gate, S.W. 1, at 11 a.m., on Tuesday, November 5, when Chrysanthemums will be exhibited in conjunction with the R.H.S. meeting.

EDWARD MAWLEY MEMORIAL.—There being a general desire amongst members of the National Rose Society that something should be done to mark the esteem and affection with which the name of EDWARD MAWLEY will always be remembered by lovers of the Rose, the Council propose that the memorial should take the following forms: 1. A stained-glass window to be erected in St. Michael's Church, Berkhamsted. 2. A medal of an approved design, to be entitled "The Edward Mawley Memorial Medal." Two of these medals will be awarded every year at the Summer Show of the Society, one for amateurs, and one for nurserymen, to the most worthy exhibits respectively in each of these sections. The Council have appointed a Special Committee to carry these proposals into effect, and the Committee now appeals for donations to the fund which has been established for the purpose. Subscriptions are limited to £1 1s., but smaller amounts may be contributed, as it is desired to include the largest possible number of names in the list of subscribers. Subscriptions should be sent to the Hon. Treasurer, Mr. PRESTON-HILLARY, 25, Victoria Street, London.

LECTURES ON FOOD PRODUCTION.—Mr. F. J. CHITTENDEN, head of the Royal Horticultural Society's School of Horticulture at Wisley, is to deliver a course of six weekly lectures on "Small Gardens and Allotments for Purposes of Food Production," at Bishopsgate Institute, E.C., on Wednesdays, at 1.15 o'clock, commencing February 20. The subjects of the individual lectures will be as follows: Feb. 20. "The Soil a Source of Supplies: Digging and Trenching It"; Feb.

27, "How to Ensure Water and Air Supplies to Crops"; March 6, "The Mineral Supply and its Effect on Crops"; March 13, "The Nitrogen Supply and its Effect on Crops"; March 20, "Seed Sowing"; March 27, "Transplanting and Spacing." Bishopsgate Institute is in Bishopsgate, three minutes' walk from Liverpool Street Station, and admission to the lectures is free.

PYRACANTHA GIBBSII (see fig. 21).—This is a new species introduced from China by Mr. E. H. WILSON. The Hon. VICARY GIBBS exhibited a specimen at the Royal Horticultural Society's meeting on January 5, 1915, under the name Pyracantha crenulata, and it received an Award of Merit from the Floral Committee. In our description of the plant in the issue of January 9 of the same year, p. 23, we stated that a form of P. crenulata had been in cultivation in this country for some considerable time. WILSON'S plant has since been found to be a distinct species, and has been named P. Gibbsii, in honour of Mr. VICARY GIBBS, in whose gardens at Aldenham the plant illustrated in fig. 21 was photographed. Mr. E. BECKETT describes the species as one of the finest of evergreen, berried plants in the very extensive collection at Aldenham. The fruits are about the size of haws, but rounder, and of a dull red colour. He states that the growth is strong, and that the plant forms a fine bush in a short time. It is perfectly hardy, and succeeds well in almost any situation. Pyracantha coccinea is a popular wall plant, fruiting more freely when grown in such a position than in the open. Mr. BECKETT is of opinion that P. Gibbsii will be equally satisfactory for such a purpose.

A NEW SENECIO.—Senecio Fernaldii is a diminutive new Groundsel, native of Newfoundland, discovered by Dr. GREENMAN. Like our common Groundsel, it belongs to the section with normally discoid heads, and occasionally develops a ray. The flowers are orange-scarlet; the new species can only be regarded as of botanical interest, and is not likely to possess any garden value.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

STORING APPLES.—I was much interested in reading Mr. BECKETT'S system of storing Apples, p. 8, and I endorse his remarks, unorthodox though they may be. During my probationary career in a garden in Wiltshire, the Apple crop was an abundant one, and storage space limited. The gardener under whom I then served used to store the fruits in heaps in barrels and in disused stables, well protecting them from frost. They had very little ventilation, yet the fruits kept plump and sound. Since then as occasion has arisen, I have never hesitated to store Apples several layers deep, and have always found that they keep much better and longer than when spread out thinly. Last season we gathered the best crop of Apples ever harvested here, and the fruits were stored thickly, with the result they are keeping better than we have had them before. Are not mistakes often made by gathering the fruits before they are mature? The fruits from trees growing in heavy, undrained clays should perhaps hang longer than is necessary on warmer, flinty, and better drained soils, where they mature earlier. *E. F. Hazelton, North Mymms Park Gardens, Hatfield, Hertfordshire.*

—Mr. Hudson's methods are perfectly correct when they can be afforded. His is the ideal method. How often, however, can ideal methods be practicable under average conditions? The economic side of fruit, flower, and vegetable production is, as a rule, of no concern to the professional gardener. He has been encouraged in the past to produce the best of everything, regardless of cost, and it is under these circumstances that Mr. Hudson and most of his colleagues write. Mr. Beckett's method of keeping fruit is not the ideal one under luxurious conditions, but it is an excellent and eminently practical one under economic limitations. If these respective honoured and skilled growers had gone to the trouble of pointing out the conducting factors of their advice, *Pomona* would not have been able justly to lay claim to the nom de plume in respect to this matter. I have kept Apples and Pears in the South as well as in the North of England under the respective systems of Messrs. Hudson and Beckett. During the past year or two I have experimented with the effect of covering Apples laid out singly on shelves with ordinary butcher-blue paper. Experimenting with 24 varieties (18 kitchen and six dessert), an average loss in weight of 7.8 per cent. over a period of three months was observed in the uncovered samples: a loss which was reduced by one-half in the case of the covered fruits. In respect to this loss of weight over a prolonged period, varieties of equally reputable keeping qualities showed considerable discrepancies. Lane's Prince Albert, for instance, lost weight at double the rate of Bramley's Seedling, although both varieties looked apparently as sound as each other at the end of the test (mid-January). The great fundamentals of good fruit keeping are, in my opinion, (a) thorough maturation of fruit on the tree, (b) careful handling, (c) a cool temperature in the store, (d) an equable atmosphere. Apples will then keep as long as their inherent keeping qualities allow. *C. W. Mayhew, Morpeth.*

SOCIETIES.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL MEETING AND ELECTION OF PENSIONERS.

JANUARY 24.—The 78th annual meeting of the Gardeners' Royal Benevolent Institution took place at Simpson's Restaurant, 101, Strand, London, on Thursday, the 24th ult. Sir HARRY VERTCH presided, and there was a moderate attendance. The secretary, Mr. G. J. INGRAM, read the notice convening the meeting, and then proceeded to read the report of the executive committee, of which the following are extracts:

EXTRACTS FROM THE REPORT OF EXECUTIVE COMMITTEE.

The Committee deeply regrets that the 78th Annual Report is not so favourable as could be wished from a financial point of view; but the greatest claims on the public for war charities have seriously told upon the income of all old-established institutions, and on none more than the Gardeners' Royal Benevolent Institution.

The enforced abandonment of the Festival Dinner, with its Annual Appeal, for the past three years has naturally resulted in a much diminished income, but, notwithstanding, the Committee are thankful to be in a position to report that, with their limited Reserve Fund, and without at present encroaching upon the Capital Funds, they have been able to maintain their work as heretofore, and to continue the benefits to the annuitants, as well as to give a much needed and from

the Good Samaritan Fund to those applicants who have applied for its help.

At the last election 18 candidates were added to the funds, making 262 in all. The Committee now recommend an election of 15 this day from an approved list of 58 applicants. They feel they are not justified in doing more than this, thus filling the vacancies caused by deaths during the past year. The 43 unsuccessful candidates will be left to rely solely upon the grants which can be made from the two supplementary Funds, viz., the Victorian Era Fund and the Good Samaritan Fund—the income only of each being available.

The Committee desire to express their sincere thanks to all the supporters of the Institution, and especially would they mention the kindness of Her Majesty Queen Alexandra in again graciously allocating a grant of money from the proceeds of "Alexandra Day." Also to those noblemen, ladies and gentlemen who have allowed their gardens to be opened to the public and the proceeds, or part of them, to be given for the benefit of the charity, viz., the Rt. Hon. Earl Beauchamp, the Rt. Hon Lord Northbourne, the Lady Battersea Sir Frank Crisp, Bart., J.P., LL.B., C. W. Dyson Perrins, Esq., and the Rt. Hon. Lord Rhidlap.

The Committee very gratefully place on record their sincere appreciation of the Golden Wedding Gift of £500 from Sir Harry and Lady Veitch which has been invested for the benefit of the charity, and they heartily congratulate them on the happy occasion.

They further desire to offer their warmest thanks to the Honorary Solicitor, W. A. Bilney, Esq., J.P.; to Messrs. George Cobley and Co., the Honorary Auditors; to the Horticultural Press, and to many other friends for their invaluable services to the Institution.

It is also necessary to refer to the kindness of Sir Harry J. Veitch, Arthur W. Sutton, Esq., Geo. Monro, Esq., and Edward Sherwood, Esq. (Trustee), for generously giving a year's allowance of money to four candidates, who are most grateful for the help afforded them and who otherwise would have been amongst those still waiting.

The several Auxiliaries are still doing excellent work for the Institution.

It is with profound sorrow and regret that the Committee have to record the death of many staunch friends and supporters during the year. Amongst the foremost of these was Mr. Leopold de Rothschild, one of the warmest friends the Institution ever had. He was President at the Annual Festival Dinners in 1889 and again in 1913 when, through his instrumentality, large sums were raised for the funds on each occasion. Other friends who will be greatly missed are Messrs. O. O. Wrigley, W. J. Lucking (a subscriber for 60 years), C. J. Druery, William Marshall, Walter T. Ware, and Albert Brassey, J.P.

HARRY J. VEITCH,
Treasurer and Chairman of Committee.
GEORGE J. INGRAM,
Secretary.

The secretary presented the financial statement, the figures of which are given below.

A telegram was then read from Mr. Arthur Sutton, regretting his inability to be present at the meeting, and renewing his offer, made in previous years, to make a grant to the Society sufficient to place on the funds the most needy unsuccessful applicant.

Sir Harry Veitch moved the adoption of the Report and Balance Sheet, and the thanks of the meeting to the Committee for their services during the past year. He said that he was thankful that the Society had up to the present been able to pay its way without touching any of the investments, the realisation of which in present circumstances would be little short of a calamity. The lack of funds was in part due to the omission, for the past three years, of the festival dinner, which in former times used to be the means of obtaining generous subscriptions. Formerly it was the practice of the treasurer to keep a large sum on deposit, but the deposit had now shrunk to about £100. The expenditure on pensions amounted to about £4,000 a year. The Committee had been considering whether it would not be possible to increase the amount of the pensions, on account of the great rise in prices of food and other necessaries. It had to be borne in mind that the receipt of anything over £30 a year was in itself a disqualification for a pension, so it would be seen that the income of even the best-off of the annuitants was very small. The Committee had therefore agreed to recommend the taking of £120 or £130 from the Good Samaritan Fund, to supplement the usual allowances, during the remainder of the war period. An anonymous sympathiser had offered a sum of £250, on condition that three other donors of £250 were to be found, or he was prepared to give more, if others would do the same, in order to extend the work of the Society. There had been many generous gifts during the year; Sir Frank Crisp had given £50, as a special donation, and the late Mr. O. O. Wrigley £50. The auxiliary Societies were doing excellent work, and a cheque for £30 had been received from Worcester that day. The Committee would like to see fresh auxiliaries opened in other towns.

Sir Harry's motion was seconded by Mr. H. J. White, and carried unanimously.

Mr. W. A. Bilney then moved the re-election of Sir Harry Veitch as treasurer, expressing appreciation of the members of Sir Harry's invaluable services, and hoping that he would remain in office long enough to receive a jubilee testimonial. This was carried unanimously, and Sir Harry Veitch briefly replied.

Mr. Geo. Monro moved the re-election of Mr. G. J. Ingram as secretary, and referred to the arduous work performed, without any help, during the year. This was seconded by Mr. Poupart and carried unanimously. Mr. Ingram, in reply, expressed his pleasure in the work, and his determination to leave no stone unturned to obtain fresh subscriptions. Mr. J. McKerchar moved the re-election of the retiring members of the Committee, which was seconded by Mr. J. McLeod and carried unanimously. Mr. Monro replied on behalf of the Committee. The auditors and arbitrators were also re-elected. At this stage of the proceedings Messrs. H. J. White, G. Cox and J. McKerchar were appointed scrutineers of the ballot, and the meeting adjourned until 4 p.m., when the result of the election was declared as follows:—

RESULT OF ELECTION.

	Age.	Votes.
Bond, Thomas W.	74	5,076
May, Martha	77	4,394
Harding, Albert	78	4,076
Parr, Henry	75	4,040
Stone, Fanny	70	4,026
Morgan, Hannah	74	3,967
Smith, Sarah A.	68	3,966
Manning, Mary	72	3,808
Bradley, George	72	3,752
Walker, George	63	3,716
Orchard, Cornelius	71	3,657
Galt, Emma A	68	3,628
Gibson, Thomas	80	3,594
Roberts, Ann	73	3,275
Milford, Sarah A.	68	3,145

The candidate Mr. Edwin Tough, in respect of whom Mr. Arthur W. Sutton last year presented the sum of £20, was this year placed upon the funds under Rule III. 10. Sir Harry J. Veitch presented £16 for a year's allowance to the applicant Mary A. Beck, Mr. A. W. Sutton £20 on behalf of Charles Bridges, and Mr. Geo. Monro £10 for the benefit of Mary Pugh, all of whom were unsuccessful in obtaining election.

ROYAL HORTICULTURAL.

JANUARY 29.—The usual fortnightly meeting was held on Tuesday last, in the Drill Hall, Buckingham Gate, Westminster. The exhibition was again a very small one, Orchids, as at the last show, comprising the principal feature.

The only awards made by the Floral Committee were four medals to collections.

Two exhibits before the Fruit and Vegetable Committee were of more than usual interest; one was a collection of Onions grown at Wisley from both autumn-raised and spring-sown plants; the other consisted of seedling Apples shown by Messrs. Laxton Bros.

Floral Committee.

Present: Messrs. H. B. May (Chairman), John Green, G. Reuthe, John Heal, F. McLeod, C. R. Fielder, J. W. Barr, J. T. Bennett Poë, R. C. R. Nevill, A. Turner, J. Dickson, C. Dixon, W. P. Thomson, C. E. Pearson, H. Cowley, E. H. Jenkins, W. J. Bean, J. Jennings, W. H. Page, A. G. Jackman, and R. C. Notcutt.

GROUPS.

Messrs. ALLWOOD BROS., Wivelsfield, exhibited excellent blooms of Perpetual-flowering Carnations. Prominence was given to a new Perpetual-Malmaison variety named Exquisite, a

large, milky-white flower, with very faint blush on some of the inner petals. The finest variety was Marv Allwood, by reason both of the beautiful colour and of the perfect form. Other noteworthy varieties were Wivelsfield White, Marion Wilson, and an unnamed scarlet seedling. (Silver Banksian Medal.)

Messrs. H. B. MAY AND SONS, Edmonton, were awarded a Silver Banksian Medal for exotic Ferns, with groups of Primula obconica grandiflora interspersed, and a row of Palms at the back.

MR. G. REUTHE, Keston, Kent, exhibited hardy plants in variety, including a box of Saxifragas in a great number of species and varieties, also some excellent little shrubs and Conifers in pots. (Bronze Banksian Medal.)

Mr. L. R. RUSSELL, Richmond, showed ornamental trees and shrubs as pot specimens. He had also large plants of Hamamelis in flower, including H. arborea, H. mollis, and a hybrid named Russelliana, of which H. Zuccariniana was the seed parent, and H. arborea the pollen parent. The hybrid has a spreading habit, and in this respect resembles H. arborea, but it is in most respects more like the seed parent, differing chiefly in its rather longer and brighter yellow petals, which are, furthermore, not so twisted as in H. Zuccariniana.

Messrs. H. CHAPMAN, LTD., Rye, showed the first new Daffodil of the season in the variety Scoutmaster, a bicolor Ajax variety, with a short, wide trumpet, prettily frilled at the edges, and with cream-white perianth. The stem is long and wiry, and the flower stands up well.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), William Bolton, W. H. White, J. E. Shill, R. Brooman-White, W. H. Hatcher, R. G. Thwaites, J. Charlesworth, R. A. Rolfe, Pantia Ralli, J. Wilson Potter, Fred K. Sander, E. R. Ashton, and T. Armstrong.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cypripedium Euryhades The Baroness (*Alcibiades* × *Leeanum Euryades*).—Shown by Mr. J. E. SHILL, The Dell Gardens, Englefield Green. A grand Cypripedium, and one of the finest developments among Euryades crosses. The large and perfectly formed flower has a circular, white dorsal sepal, of fine substance, with a pale, gamboge yellow base, the surface bearing large, deep claret blotches, changing to rose towards the margin. The petals are broad, honey yellow in colour, with claret spotting on the basal half, the outer half and the lip being tinged with deep mahogany-red.

Cattleya Monarch Bryndir variety (*Trianae* × *Empress Frederick*), from Dr. MIGUEL LACROZE, Bryndir, Roehampton (Orchid grower, Miss Robertson). A perfectly formed flower of large size and very fine colour. The sepals, and nearly orbicular crimped-edged petals, are light blush rose, the well-rounded lip rich ruby purple in front, with gold lines running on a rose-coloured ground from the base, and a light yellow patch on each side of the tube.

PRELIMINARY COMMENDATION.

Odontoglossum wGatton Princess (*Queen of Gatton* × *eximium*), from Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. Collier). A worthy descendant of O. Queen of Gatton, which is the finest yellow ground Odontoglossum, its perfect shape being reproduced in the seedling, although the desirable yellow ground has been lost. The surface of the flower is almost covered with deep ruby claret blotches, the white appearing only in slight markings and at the margins of the segments.

OTHER NOVELTIES.

SIR JEREMIAH COLMAN, Bart., showed flowers of Cypripedium insigne Gatton Park variety, an improvement on Harefield Hall and Odontioda Bradshawiae, raised from two forms of Bradshawiae, the bright red flower showing a further advance towards Odontoglossum, and elimination of the features of Cochlioda Noezliana.

Dr. MIGUEL LACROZE exhibited Sophro Laelio Cattleya Isabella (S. C. Marathon × C. Fabia), of indifferent shape, but very bright colour, and Brasso-Cattleya Bianca majestica, a blush-white flower flushed with pale pink.

Colonel LEITH, Grey Court, Riding Mill-on-Tyne (gr. Mr. Jas. Renwick), showed Odontoglossum Colonel Leith (Rossii × Uro-Skinneri), an interesting hybrid, intermediate between the two parents. The sepals and petals are densely spotted with chocolate-red. The lip is tinged with pale lilac, the fleshy crest being whitish and the slender column tinged with rose.

GROUPS.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Flora Medal for a fine group of Odontiodas, Cattleyas, and Odontoglossums. The finest plant of a selection of their famous strain of Odontoglossums flowering for the first time was O. Corona (eximium × Menier St. Vincent), a large and broadly proportioned flower. The inner parts of the sepals and petals are claret-red, the outer segments and the margins white. The lip is white in front, and marked with purple around the yellow crest. Other fine new forms were O. Orissa (ardentissimum × Hylandianum), O. Fabia splendens (Aglaon × eximium), and Sophro-Cattleya Niobe (S. C. Saxa × C. Octave Doin), a pretty new hybrid, with neatly-formed flowers of cream colour slightly tinged with pale rose. The lip is yellow at the base, the front and margins of the side lobes ruby-red.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group of Odontoglossums, Laelio-Cattleyas, Cypripediums, and others. Specially noteworthy were Vanda teres alba, pure white; Odontioda Joan var. pulcherrima, brilliant scarlet; and Odontoglossum Thwaitesii rubescens.

Messrs. HASSALL AND CO., Southgate, were awarded a Silver Banksian Medal for a group of Cymbidiums, including Alexanderi, Moira, Sybil, and Capella, and the new Odontoglossum Sybil (Thompsonianum × Aireworth), a flower of medium size, dark claret in colour, with white tips and margins.

Messrs. SANDERS, St. Albans, staged a small group in which were noted Cymbidium Albatross, one of the largest and best formed flowers; Brasso-Cattleya Fascinator (R. C. Digbyano Mendelii × C. Enid); and the pretty Sarcolabium bellinum magnificum.

Fruit and Vegetable Committee.

Present: Messrs. W. Pompart (chairman), W. Bates, W. H. Divers, Edwin Beckett, A. Bullock, E. A. Bunyard, G. P. Berry, J. G. Weston, and Owen Thomas.

From the Society's gardens at Wisley a collection of Onions was exhibited, representing 87 stocks raised from autumn-sown plants, and 45 stocks from spring-sown stocks. It was clear from a comparison of the two exhibits that the autumn-sown plants were in every way superior to those sown in the spring; they were firmer, larger, and had the deep russet-brown skin which betokens late keeping quality. The following varieties were the best: Autumn Triumph, Giant Zittau (Harrison's strain), Froxfield, The Sutton Globe, Yellow Giant Zittau, and Brown Globe. The latter was not exceptionally large, but the specimens were very firm and solid. The weight of the produce obtained per hundred plants was given, and the best croppers were Autumn Triumph, 62¼ lbs.; Trebons, 60½ lbs.; Giant Zittau (Harrison's), 54½ lbs.; White Spanish, 47½ lbs.; Yellow Giant Zittau, 46¼ lbs.; Cranston's Excelsior, 40½ lbs.

Mr. A. DAWKINS, Chelsea, showed splendid bulbs of Onion Autumn Triumph.

Messrs. LAXTON BROS., Bedford, exhibited seedling Apples, many of which had Cox's Orange Pippin in their pedigree. It was to be regretted that the fruits were past their best condition, and it was difficult to appraise their merits. Some were of exceedingly good flavour, and a few, including Laxton's Superb and Worcester Pearmain × Cox's Orange Pippin, attractive in appearance. Court Pendu Plat, a very late-blooming Apple, and valuable on that account as escaping injury from spring frosts, was used as a parent with Cox's Orange Pippin. The fruit resulting from this cross was of good flavour, and a promising late Apple. The reciprocal cross gave a fruit very like Cox's Orange Pippin, and seemed as if it would prove a valuable acquisition. It was named William Watson; most of the others were shown under numbers only.

Messrs. WATERER, SONS AND CRISP, LTD., Twyford, exhibited a new Apple named Park Royal, closely resembling Bess Pool. The fruits were of good appearance and in fine, solid condition.

CROPS AND STOCK ON THE HOME FARM.

SEASONABLE REMARKS.

ALTHOUGH the frosty weather hindered the sowing of late Wheat, it has had a beneficial effect on the land, and the soil will be in excellent condition when the time arrives for the sowing of spring Corn—Oats, Barley, and Wheat. Where stiff land has been ploughed after Wheat, Mangolds, Turnips, Potatos, and other crops, the pulverising effect of the frost on such land will be beneficial in providing a good tilth in February and March for the early sowing of Oats. Whenever possible, keep the plough going, even while the frost is keen, but when the ground is too hard for this work other occupation must be found for the horses, such as getting manure on the land for the Potato and Mangold crops, and the carting and spreading direct on the land of gas lime. The value of gas lime is much underrated by many, especially where finger-and-toe or club disease is troublesome to Turnips and Brassicas. Where Potatos are to be grown on the same site a second season, or where grass land is to be ploughed for this crop, gas lime spread over the surface at the rate of 2 tons per acre will have a sweetening effect and do much to check wireworms and slugs. Personally, I do not fear wireworms to any serious extent in Potatos in newly ploughed-up grass land; the effect these pests have is more imaginary than real. If the lime is fresh from the gas works it will be well to allow it to lie on the surface for a time to lose its more caustic properties, and especially where a heavier dressing than is necessary should have been given. When used in excess, gas lime is injurious to crops for a season or two. Chalking the land is excellent work for frosty weather; not nearly enough chalk is employed on the land. When one considers its sweetening influence on soils, acting in the same manner as lime, only in a lesser degree, in setting free the humus collected in the soil, especially where heavy dressings of manure have been employed for such crops as Mangold and Potatos, its value is considerable. Our forefathers valued this natural means of enriching the land much more than we do. Stiff, heavy, clay soils are much improved by a dressing of 20 tons of chalk per acre. Spread it direct from the cart on to the land, when frost will cause the lumps to crack and crumble. Chalk has a more lasting effect on the land and crops than slaked lime, which is, however, more rapid in its action.

Good roads are a convenience. Many people when repairing roads that have deep ruts fill the depressions with hard material, such as stones, broken bricks, and coarse gravel, instead of clearing out the loose soil and mud first, with the consequence that the road is little better than previously. Thoroughly clear away all soft matter to ensure a solid foundation before applying the stones. In cases where extra soft and deep places are present a layer of hedge trimmings or faggots will make an excellent foundation and save much hard material.

The clearing away of refuse in the rick yard is useful work to do in winter. Straw should be carted into the yards for the store cattle or put into heaps to be temporarily thatched to preserve it in good condition until required. Where Corn that is much infested with Docks or Thistles has been thrashed the extreme refuse should be deposited in an out of the way corner where fowls can scratch it over. On no account should such litter be added to the manure heap or carted into the yard, as the weed seeds it contains would do much harm to future crops. The cutting of hedges is useful occupation for the staff. Many hedges in this part of the country have been neglected in the last year or two and they need drastic treatment to get them in good condition again. I am cutting many overgrown hedges around cornfields close to the ground, as from experience gained last harvest there is a difficulty in drying the Corn properly within several yards of overgrown hedges. *Edwin Molyneux.*

REMARKS: There has been a general increase in the quantities of cut flowers during the past week, and prices are greatly reduced, especially for coloured varieties. Home-grown Daffodils, such as Golden Spur, Princeps, and Emperor, are arriving in good condition. Boxes of Pheasant Eye Narcissus are being received from the Spalding district. Tulips are available in the following varieties: La Reine (white), Prince of Austria (bronze), Murillo (double pink), and a few bunches of mauve, which find a ready sale. Snowdrops are also arriving in excellent condition. The supplies from the Channel Islands are gradually increasing, the chief kinds are Yellow Narcissus Soleil d'Or, Daffodils, white Narcissus Grand Primo, and a few boxes of Paper-white Narcissus and Freesia. French flowers, although more plentiful, are not in demand owing to the poor quality. Many blooms are unsaleable when they arrive here. Colder weather might improve their condition.

The Plant Market is entirely closed for the present.

Walnuts, French, kiln dried, per bag	23 0–120 0	

REMARKS: A fair quantity of English Apples is arriving, chiefly Bramley's Seedling, Dumelow's Seedling, and Lane's Prince Albert. Cases of French Russets are also obtainable. Black Alicante and Gros Colman Grapes are available, but supplies are decreasing. There are still large supplies of Almerias (Spanish). Lemons and Oranges have advanced in price. The following forced vegetables are on offer this week: English Asparagus, Paris Green and National Asparagus (French), Mushrooms, Seakale, Chicory, Cucumbers. There are fairly large quantities on offer of Garlic, Shallots and Onions (Valencia and French). The market is well supplied with all ordinary vegetables and roots. *E. H. R. Covent Garden Market, January 30, 1918.*

Obituary.

G. TURNER.—We regret to record the death of Mr. G. Turner, at Malden, Surrey, on January 13, at the age of 72 years. He had recently recovered from a short attack of bronchitis, but died from a heart attack.

MISS ETHEL SARGANT.—We learn with regret of the death of Miss Ethel Sargant, F.L.S. Miss Sargant was distinguished for her researches in botany, and was the first woman president of a section of the British Association. She died at Sidmouth on January 16, at the age of 54.

F. MENTEITH OGILVIE.—We deeply regret to announce the death of Mr. F. Menteith Ogilvie, The Shrubbery, Oxford, who died recently from pleurisy and pneumonia after a very brief illness. Mr. Ogilvie was one of the oldest and most successful of Orchid enthusiasts, and his collection at The Shrubbery was one of the choicest and best-cultivated in the home counties. He was for many years a member of the Orchid Committee of the Royal Horticultural Society, and a frequent exhibitor of new and rare Orchids.

ENQUIRY.

CAN any reader inform me where I can obtain plants of the old Perpetual-flowering Carnation "H. Elliott"? *F. W.*

CELERY DISEASED: *Miss P.* The disease to which you refer is probably Celery Leaf Blight, Cercospora apii, a fungus causing yellowish spots on the foliage. Spray the plants with ammoniacal carbonate of copper soution when they are young, and repeat the spraying occasionally during the period of growth.

CITRUS MITIS: *Amateur Gardener.* The idea that Citrus mitis is a hybrid between Aegle sepiaria and the Sweet Orange of Florida has no foundation in fact. It is a native of the Philippine Islands, and was first described in 1837 by Blanco in his flora of those isles, where it is considered to be a distinct species, but in the latest edition of Blanco, *Flora Philippinarum*, Appendix, p. 37, published in 1880, it is stated to be identical with C. limetta. In Bailey, *Cyclopædia of Horticulture*, Vol. 2, p. 784, 1914 edition, it is, however, retained as a distinct species. The account of it there states that: "This tree, a native of the Philippine Islands, is commonly cultivated in Hawaii, where it is wrongly called 'China Orange.' It was introduced into Florida by the U.S. Dept. of Agriculture from Panama, and was for a time distributed by nurserymen under the erroneous name of To Kumquat. It is very hardy, probably as hardy as the Satsuma, or even more so. It can be budded on Sour Orange or on Trifoliate stocks." In America this hardy Orange is stated to be a promising fruit for home use, for culinary purposes. We have no knowledge of its cultivation in England or Ireland, but doubt if it would produce palatable fruit in this climate.

CUCUMBER SOIL FOR ALLOTMENT: *L. F.* You can spread the old Cucumber soil over your allotment now, but if there was any eelworm present on the roots of the Cucumbers last year, you should first sterilise the soil by baking or steaming, otherwise the eelworm will be communicated to the fresh soil. The lime can also be applied at the present time, but it will be better to defer using the Vaporite until later in the season, when the ground insects are more active.

FERTILISERS: *Potassa.* You may apply the superphosphate to your vegetable plot after the ground has been dug and prepared for sowing and planting. Superphosphate and sulphate of ammonia are excellent manures for Potatos, and if the former is applied at the time when the rows are made for planting, it will become incorporated with the soil, but at not too great a depth. The sulphate of ammonia may be used along the rows when the Potatos are sprouting through, but take care not to allow it to touch the foliage. With regard to the packet labelled No. 1, we think you are correct in assuming it to be some form of nitrate, but it is certainly not nitrate of soda, which, as you say, deliquesces in winter. Your friend, from whom you obtained the manure, should know best what the "No. 2" sample is; in any case, if you know that they are garden fertilisers, there would be no harm in using them, but try the effect of a little at first.

HYDRANGEA: *K. M. S.* Cut the plants of Hydrangea down to the ground at once, and give the roots a top-dressing of rich loam and manure at the same time if it is not possible to turn them out and repot them. When growth commences thin the shoots to leave only a few of the strongest, the number being according to the size of the plant. Feed the roots with liquid manure at least once a week. To obtain the blue colouring is a difficult matter, but you might try sulphate of iron in small, regular doses throughout the growing season. Powdered alum has also been recommended for producing the blue colour in the flowers.

PROPAGATING SHRUBS: *D. C.* You can propagate Daphniphyllum glaucescens, Lonicera Hildebrandtii, and Viburnum Carlesii by means of half-ripened wood in gentle bottom heat in August. The various ornamental vines, including Vitis inconstans (Ampelopsis Veitchii) can also be increased in the same way, or, in the case of the larger-wooded kinds, by means of eyes, in the same way as Grape vines are propagated. Idesia polycarpa can be rooted from soft cuttings taken early in the year and put in brisk bottom heat, but these are difficult to deal with. All these plants root readily when layered, which is the easiest way to propagate them if it is possible to do so. Trochodendron aralioides can only be increased by seeds, which are freely produced on old plants. Most of the Cotoneasters come true from seed, the exceptions being some of the varieties, but cuttings of all can be rooted as advised above, or outdoors in a sheltered spot in winter.

NAMES OF FRUITS. *A. G. Gentle.* 1, Da Hogg; 2, Barbarossa (?); 3, Gros Colman; 4, Gros Maroc; 5, Lady Downe's; 6, Muscat of Alexandria. (For satisfactory identification a whole bunch of fruits and a well-developed leaf of each variety should have been sent.)—*J. J. W.* Shepherd's Newington.—*Motyar.* Apples: 1, Hormead Pearmain; 2, Flower of Kent; Pears: 1, decayed; 2, not recognised; 3, Catillac; 4, decayed; 5, Uvedale St. Germans; 6, decayed.—*E. W. B.* 1, Norfolk Stone Pippin; 2, Dutch Mignonne (syn. Reinette du Caux); 3, Golden Noble; 4, Adams's Pearmain.—*S. A.* Apple Lady Henniker; Pear Glou Morceau.—*Shropshire.* 1, Cellini; 2, Broad End; 3, not recognised; 4, Margil; 5, decayed; 6, Calville Rouge d'Hiver; 7, Cockle Pippin; 8, Newtown Pippin.—*A. H. C.* 1, Queen Caroline; 2, Melon Apple; 3, not recognised.

NAMES OF PLANTS.—*Correspondents not answered in this issue are requested to be so good as to consult the following number.*

1 *H. C.* Phillyrea decora (P. Vilmoriniana). *Conifer.* 1, Libocedrus decurrens; 2, Phlomis fruticosa; 3, Berberis vulgaris; 4, Clematis sp. (send in flower).

TREE DISFIGURED: *A. C. B.* In the absence of any special provision in the tenancy agreement, the tenant's duty would be to see that the tree is pruned with reasonable care and skill; if, for want of this, the tree has been injured, the landlord would have a claim for damages. The latter would, however, have no right to enter and cut down the tree merely because it now disfigures the view from his premises.

NOTES FROM KEW. II.*

HYBRID Cymbidiums are a great horticultural achievement. The introduction of C. insigne from Annam about ten years ago made them possible. Before we possessed this species our garden Cymbidiums were either on the coarse, dull coloured side, typified by C. Lowianum, or were not good garden plants, which I think is an honest opinion of C. eburneum. Not only is C. insigne a winter flowering species, it is also stately and handsome, and if the spike is overlong it is a good fault. By crossing C. insigne with the other species breeders have produced a race which is likely to hold for ever a foremost place among the best decorative Orchids. There is a good set of these hybrids at Kew, thanks largely to Sir George Holford, who presented some of his best varieties, and they are now in flower. Cattleya treatment appears to suit them exactly, except that, being gross feeders, they need a strong, loamy soil. The spikes of flowers when cut are superb for decorative uses, and they keep fresh for weeks too long, perhaps, for those people who soon tire of things beautiful.

A plant pathologist in quest of a promising subject for research might give his attention to the behaviour of Orchid roots. Every experienced Orchid grower has been troubled by the death of the roots of Cattleyas, Odontoglossums, Dendrobiums, and others, from no evident cause. It does not appear to be due to excess of moisture during the resting season, nor to drought. Since I have been connected with Kew, Odontoglossums have lost practically every root during the winter, even although the plants had filled their pots in summer with roots like a ball of twine. And it is the same to a large extent with Cattleyas. This annual loss of roots is accompanied by considerable shrinking of the pseudo-bulbs, so that when the plants begin to pick up in spring they have losses to recover before they can make new growth. It is not a question of soil; of that I am certain; but it may be one of atmosphere. There is poison enough in the air at Kew, and especially in winter, to cripple expanding flowers and foliage. Orchid roots are said to have a porous, paper-like skin which absorbs moisture from the air. Every part of the living root does this. In dry weather this papery covering prevents transpiration from the root-cells, and in wet weather condenses and supplies water to them. To put it roughly, the outer bark of Orchid roots is a water catcher and holder from which the root cells are fed.

The following experiment with Orchids may be of interest to growers. About three years ago half a dozen small plants were potted in ordinary sponge to test it as a substitute for peat fibre. Sponge, being clean and lasting, possesses in its other properties, so it was thought, exactly what epiphytic Orchids require. The result is interesting, the plants having rooted freely in and about the sponge, the roots and leaves being quite healthy. Although the same sponge has been in use over three years, it is still tough and porous. The experiment is being repeated on a larger scale with Cattleyas, Dendrobiums, Vandas, Phalaenopses, Bulbophyllums, Stanhopeas, Odontoglossums, and Oncidiums. Sponge "trimmings" can be purchased at a reasonable price compared with the present price of Osmunda-fibre. Besides, Osmunda and all Fern roots in use for this purpose break down too quickly, and are then mischievous.

The genus Celmisia continues to puzzle British gardeners. A few years ago we thought at Kew that the secret of growing the plants had been hit upon; a corner outside the Temperate House, shaded all day by the walls of the building, was heaped with sandstone and peaty soil, in which about a dozen species flourished for several years, but after that they steadily declined, and we could not perceive why. Captain Dorrien-Smith, who visited New Zealand some ten years ago, brought home a collection of living plants and information as to the conditions in which Celmisias grow wild: he considered that a wet soil and full exposure to sunshine were the essentials to success. So some were tried in the rock garden at Kew, where they have been for about five years. The plants are evidently hardy enough to live through our winters, as they look little the worse for the recent severe frost. Still, they have not made good. I saw the plants at Tresco, in fact, helped Captain Dorrien Smith to plant them, nine years ago, and they may have done better than the Kew plants. Celmisias are worth struggling with, for if we could discover their secret and get them to do their best in this country they would add a new and charming feature to the Alpine garden. The species growing in the Kew rockery

FIG. 22. CELMISIA SPECTABILIS (see p. 52)

* A previous article appeared in the issue of January 19.

are C. verbascifolia, C. Munroi, C. grandiflora, C. petiolata, C. Lindsayi, C. spectabilis (see fig. 22), C. hieracifolia, and C. holocericea.

The first Rhododendron to flower outside this year was R. parvifolium, the second being R. mucronulatum, which might well be called the Japanese form of R. dauricum, another early species. When flowers are scarce out-of-doors, these Rhododendrons are most welcome, otherwise they are of the small fry of the genus. The few days of sunshine between January 21 and 25 brought them out with a rush, as also it did the Winter Sweet, Yellow Jasmine, and the Witch Hazels (Hamamelis). A group on a large scale composed of Hamamelis, Yellow Jasmine and Winter Sweet would be a pleasing feature in any large garden or park; with Christmas Roses as a ground setting the combination would be better still.

What a fine forcing bush Rhododendron racemosum is (see fig. 23). It has been forced for the greenhouse at Kew for the past three winters, but they are none the worse. I may state that fire-heat is not used in the Himalayan wing of the Temperate House unless frost is severe, a few degrees not mattering for the inmates of this house. Evidently the Lobelia cannot bear frost.

There is some danger of the beautiful Malayan Rhododendrons raised by Messrs. J. Veitch and Sons being lost to cultivation. The only collection of them known to me is at Kew. At the R.H.S. fortnightly meetings some years back an exhibit of cut blooms of these Rhododendrons formed a part of Messrs. Veitch's "stall," and it was Mr. John Heal's boast that he had been able to show them at every meeting for several years without a break. The plants require more heat than other Rhododendrons, for they are stove rather than greenhouse plants, and they easily get out of condition. But they are worth whatever their successful cultivation may cost, and it is to be hoped some nurserymen will continue to grow them. No one has succeeded in hybridising Rhododendrons proper with these Vireyas, as Blume, a Dutch botanist, called them: indeed, there are very good characters of habit, foliage, flowers and fruit to support Blume's view that they are not Rhododendrons. Among the many successes of Mr. John Heal in hybridising I would give first place to his work with these plants. Cuttings of the young shoots, if inserted in a close propagating frame, root freely at any time of the year. The plants are always making new growth, consequently they have no definite flowering season; growing shoots and open flowers occur together, as may be seen on the plants in the Temperate House at Kew, where for some time there has been a good show of the flowers.

Mr. H. Kempshall, Abbotsbury Gardens, writes me that in the winter garden there Buddleia asiatica is grown as a climber to flower in winter, and that he has measured flower-sprays 27 inches long, their fragrance being delightful. He also grows, under the name of B. Colombae, a plant obtained from a Continental garden by the late Lord Ilchester, which I find, on comparison, is B. officinalis (*Bot. Mag.*, t. 8401), a Chinese species, introduced by Wilson and flowered in a greenhouse at Kew in November, 1910, continuing to flower till the following February. It has grey-green, lanceolate leaves and fragrant flowers in compact axillary tufts; the blossoms are mauve colour with a ring of red at the mouth of the tube. Both this species and B. asiatica are worth growing in pots with Chrysanthemums to flower under glass in winter.

How is it that soil beds under glass so quickly get out of condition? Good loam or peat, or a mixture of both, may be used according to the requirements of the plants to be grown, but in a few years it becomes a close, fibreless, sludge-like mass, in which no plant can grow healthily. This does not happen when the beds are in the open. Beds in the Palm House and Temperate House at Kew invariably behave in this way, and it is no light matter to renovate them and not injure the plants. *W. Watson.*

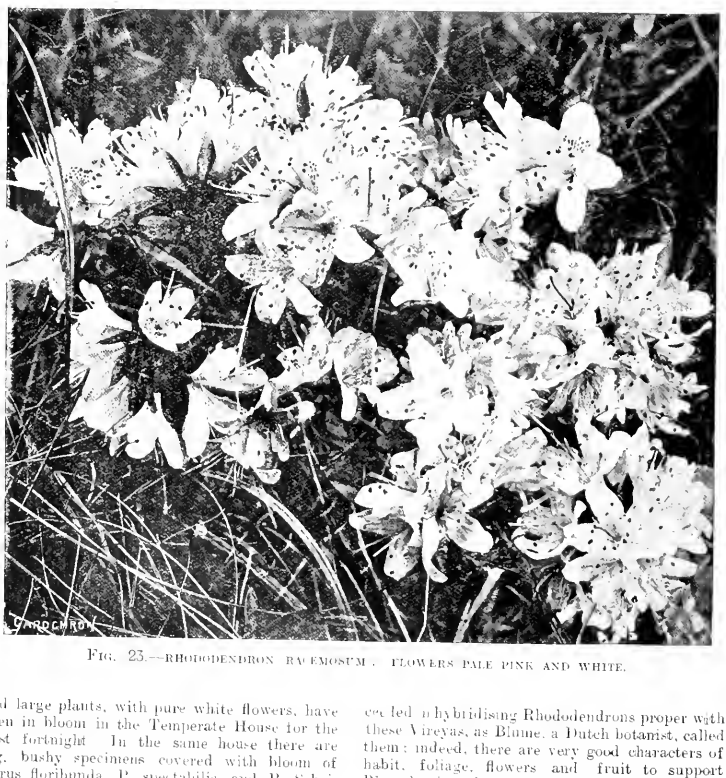

FIG. 23.—RHODODENDRON RACEMOSUM. FLOWERS PALE PINK AND WHITE.

and large plants, with pure white flowers, have been in bloom in the Temperate House for the past fortnight. In the same house there are big, bushy specimens covered with bloom of Pyrus floribunda, P. spectabilis, and P. Scheideckeri, three of the best shrubs for forcing. A tree like specimen with many branches bearing huge heads of bright yellow flowers of Senecio grandifolius (Ghiesbreghtii), and a good show of Acacia cultriformis, A. pulchella, A. pravissima, A. juniperina, and A. longifolia, with numerous other species to follow shortly, are the present floral attractions of this house.

Several tall, big-leaved plants growing with the Himalayan Rhododendrons arrest the attention of visitors. There are tree Lobelias from Mount Kenia, British East Africa, an account of which, with illustrations, appeared in the *Gardeners' Chronicle*, March 4, 1916, p. 125. The Kew plants are about 10 feet high, with a thick, unbranched stem and broad leaves a yard long; when they flower they promise to be imposing. Recent frosts have nipped their leaves somewhat.

ORCHID NOTES AND GLEANINGS.

NEW HYBRIDS.

CYMBIDIUM VIRGO.—A flower of this new hybrid, raised between C. Woodhamsianum (Lowianum × eburneo-Lowianum) and C. Pauwelsii (insigne × Lowianum), is sent by Mr. W. Walker, gardener to G. Hamilton-Smith, Esq., Northside, Leigh Woods, Bristol, in whose gardens hybrid Cymbidiums are well represented. In this cross, as in the case of C. Woodhamsianum, C. Lowianum is closely followed in every feature, and the influence of C. insigne and C. eburneum, except in inconspicuous details, obliterated. It is a well-formed flower, 4 inches across, having sap-green sepals and petals with darker lines along the nerves. The lip is cream-white tinged with green on the side lobes, the front lobe bearing the broad chestnut-red band characteristic of C. Lowianum within the whitish margin.

ODONTIODA LUMINOSA.—A flower of this handsome hybrid, raised from Odontoglossum Rossii rubescens and Odontioda Charlesworthii (Cochlioda Noezliana × Odontoglossum Harryanum), is sent by Richard Ashworth, Esq., Ashlands, Newchurch, near Manchester, in whose garden the plant first flowered in 1915. The neatly formed flower is very attractive, and has a remarkable contrast in colour. The sepals and petals are deep vinous-red with a faint gold shade; the lip, which plainly indicates O. Rossii, is cream-white at the base, with a prominent claret coloured crest, the front lobe being bright rose shading to rose-purple in the centre.

ODONTOGLOSSUM SEEDLINGS.—Mr. Ashworth also sends flowers of three finely coloured seedling Odontoglossums. Two of the varieties have heavy violet markings, and it is desirable that this colouring should be preserved, which might be done by fertilising with their own pollen and selecting from the progeny, rather than crossing with brown or red-tinted forms, which generally results in suppressing the violet. The one labelled No. 1 is specially rich in colour. No. 2 is between O. Lambeauianum Mars and O. crispum Thompsonianum (which makes it a form of O. Aireworth), a finely shaped flower mainly of violet colour, the white ground showing only at the margins and in a few places between the large, confluent, violet blotches. No. 3 is a cross with O. loochristiense (harvengtense), and has lost the yellow of that parent, the flower being pure white heavily blotched with purplish-brown.

Flowers of O. excellens Ashworth's variety, a large canary-yellow bloom with some dark red blotches on each segment; O. Gladys, and a fine pure white O. crispum xanthotes are also sent by Mr. Ashworth.

CYPRIPEDIUM STONE-HOUSE.—A flower of this pretty new hybrid between Cypripedium Leeanum Clinkaberryanum (Spicerianum × insigne)

and C. triumphans nitens Sallieri × œnanthum superbum, is sent by H. Worsley, Esq., Sherfin, Baxenden, Lancashire. C. Leeanum Clinkaberryanum influences the form of the dorsal sepal, which is broad and finely shaped, pure white with an emerald green base, from which radiate lines of rose-purple spotting in the medium area. The broad petals are undulated at the margins and bear closely-arranged lines of dark purple spots on a pale greenish ground. The lip, which is larger than that of either of the parents, is reddish-brown, with margin and base of pale yellow. The staminode in form reverts to the original species in its ancestry, and is a compound of C. Spicerianum and C. insigne.

ODONTOGLOSSUM CORONA. — The Odontoglossum illustrated in fig. 24 is a hybrid between O. eximium (ardentissimum × crispum) and O. Menier St. Vincent (amabile × gandavense). The plant was shown at the Royal Horticultural Society's meeting on January 29 last, by Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, amongst a number of hybrid Orchids flowering for the first time. The hybrid well demonstrates the advantage of pursuing a definite line in hybridising, the basal species in the parents being O. crispum and O. Pescatorei, with the introduction of rich colour through O. Vuylstekeae in O. Menier. O. Corona excels in size, form and colour any of its parents, the inner parts of the segments being dark claret-red, the margins and tips white, with a slight rose shade obtained from the purple tint of the reverse side. The lip, which is white in front, is marked with ruby-purple at the base.

THE MARKET FRUIT GARDEN.

JANUARY was a month of great fluctuations of temperature. In the first half of it the wind was generally in a cold quarter, and frosts were frequent, while in the second half the weather was mild as a rule, and occasionally quite warm for the time of year. A frost of 17 degrees on the night of the 8th instant raised the question whether it was not the maximum for my station during my seventeen years of residence in my present home. Reference to my first record for sixteen winters previous to the present season, however, showed that it had been exceeded twice, namely, by 20 degrees on the night of February 2, 1912, and by 19 degrees on that of March 4, 1909. These figures refer only to registration at the level of my house, 100 feet above sea level. Greater severity has been twice noticed at a much lower level, namely, 23 and 22 degrees, but there has been no regular record for that position, and possibly the latest severe frost was several degrees greater in the lower than in the higher position. Again, in the matter of rainfall, the danger of assuming that a very heavy one for 24 hours was a "record" was demonstrated by reference to a daily register begun here at the beginning of 1901. For the day and night of January 15 last the measurement was 1.73 inch. This was equalled on December 21, 1909, and exceeded on three occasions, as follows: 3.06 inches on July 23, 1903; 2.28 inches on October 26, 1909; and 2.07 inches on September 30, 1912. But measurements exceeding 1 inch for twenty-four hours have been extremely rare. In the past month rain or melted snow was measurable on 15 days, amounting to 3.77 inches. In the first half of the month snow was more frequent and heavier than usual, but showed no approach to the depth reported in many parts of the country.

DRAINS IN FRUIT PLANTATIONS.

Winter never fails to show that a drain here and there in one or some of my fruit plantations is blocked, so that the pipes affected have to be taken up and cleared. The most frequent cause is the filling of the pipes with the roots of Black Currants or shelter trees. Drains in one field, made before it came into my possession, run under a hedge into a ditch, and some supplementary new ones also. The result is frequent blocking by the roots of hedge shrubs or the shelter trees which I planted some years ago. Black Poplar and Cupressus. The former is a bad offender, and we have found its roots running up into the field to a distance of eight or ten yards. The roots of Black Currants will block drains lying at a depth of 3 feet. Apple roots occasionally get into the pipes, but rarely block them entirely. It is a great mistake, in draining land, to lead a number of single rows of pipes into separate outlets in a ditch, whether they have to go under a hedge or not. The two or three pipes close to the place of outlet for the water in them are almost certain to drop, through the loosening of the earth around them, and then there may be partial blocking. Or the outlet may be blocked by earth scraped over it by mice, rats, or rabbits. The better way is to lead the single drains into a main drain, or more than one if the lie of the land renders it more necessary. Then the outlet or outlets can be bricked up or cemented. But, apart from such causes of blocking as are referred to above, drain pipes, in course of time, get gradually filled with silt. This is particularly the case where the silt is heavy, as it is where there is much iron in the soil. At the present time I am draining a recently purchased field, the subsoil of which contains more or less ironstone in places, which is not astonishing, as the district was an important iron-smelting one in the distant past, before the industry was monopolised by the coal districts. About thirty years ago this field was drained in good style, the single drains being led into a 6-inch main. This I knew nothing of when I began to lay a main, hitting upon precisely the same position for it. As soon as the work was begun the outlet of the old main was discovered, water still issuing feebly from it. We then followed the old main, taking up the pipes and clearing out of them the silt, permeated with iron oxide, with which they were partially or wholly filled. Fortunately there is a spring, which runs all the year round, in a ditch at the side of the field at which the main starts, and this has been led into that end of the main, in order that the pipes may be constantly washed by a stream of water. Similarly the single drains led into the main were found more or less full, and a 4-inch and a 3-inch drain were followed and cleared, while 2-inch drains are being left as they are, as it is easier, if not cheaper, to lay fresh drains than to follow the old ones, clear them, and re-lay them. The same difficulty with iron silt has been experienced in two other fields drained in earlier years.

PREMATURE HATCHING OF INSECTS.

The finding of a Mottled Umber caterpillar, about half grown, on an Apple tree on January 25, reminds one of the desirability of an occasional warm spell in winter, to be followed by somewhat severe frost. That stem-mother aphides are often hatched prematurely is well known, and their destruction shortly afterwards by frost is of more advantage than almost any amount of spraying. Possibly the extraordinary immunity from aphis attack last season was due to premature hatching followed by frost. That this was the case in one of my plantations of young Apple trees is certain, as a number of badly infested trees were quite cleared of Aphis avenæ (or Fitchii, as formerly called) by a frost of only 2 degrees. I have no evidence of the destruction of Apple suckers or caterpillars by frost, but possibly fruit growers in districts more subject to late frosts than my own is may have such evidence.

FIG. 24.—ODONTOGLOSSUM CORONA.

APPLE STOCKS.

Remarks concerning the Doucin as an Apple stock in the Report of experiments under the auspices of the Wye Agricultural College at East Malling, Kent, to the effect that it grows as freely as the Free stock, are strikingly confirmed by the growth of trees in my orchards grafted on Doucin, Crab, and Free stocks respectively. Nearly all the trees in three of my Apple orchards were grafted or budded on my own farm, and it is only to these that I am about to refer, because, of course, I have no certain evidence of the trueness of stocks in cases of purchased trees. The Doucin, Crab, and Free

stocks used were remarkably good ones, and, it may be said, equally good. Now, in two orchards there are several varieties of Apples raised partly on all three stocks, and in one other orchard Doucin and Crab can be compared. On several occasions I have inspected these trees, in order to note any differences in growth from the different stocks, and on each occasion my note was "No difference." This means no difference, so far as I could see, in average sizes of trees in rows or parts of rows of the three or two stocks. The only distinction noticed has been more marked lack of uniformity of size in trees on the Free stock than in trees worked on the other stocks. This is not surprising, because Free stocks are generally, if not always, raised from the pips of mixed varieties of Apples from cider mills. Perhaps the most remarkable lack of difference in growth is found in two orchards in which trees grafted on stocks supplied to me as Broad-leaf English Paradise are as big as trees grafted on Doucin stocks side by side with them. But it is possible that the stocks supplied to me as English Paradise were Doucin stocks, as it is reported that some nurserymen send out the latter under the name of the former. In all the cases referred to the trees have been planted from eight to eleven years.

No Sugar for Home-made Jam.

The announcement that there is no prospect of sugar being available for home-made jam is one of alarming purport to fruit-growers. Householders are advised to save sugar for jam out of their very meagre weekly allowance, but it is doubtful if many will exercise the necessary self-denial. It is to be hoped that the authorities will find later in the season that they can do better than they expect at present in respect of the sugar supply. Otherwise, in the event of the Plum crop being a good one, it is almost certain that the demand will be so very much below the possible supply that half the crop will not pay for picking and marketing. The demand for several other kinds of fruit will also be affected by shortness of sugar, but that for the Plum crop will be most seriously reduced. Country cottagers, who grow fruit in their gardens, and rely largely upon jam as food for their children, will be seriously inconvenienced if sugar for jam-making should be lacking.

Dearness of Spraying Stuffs.

Another serious difficulty for fruit-growers is the dearness of materials for spraying. A good brand of soft-soap, for which I paid 18s. 9d. per cwt. in 1914, is now quoted at 65s. 8d., which is almost prohibitive for extensive use. Lime-sulphur also has gone up greatly in price—so much that I shall limit my use of it to application to trees subject to scab, unless some should be also required to protect Plum buds against birds. So far as I have observed, lime-sulphur, on trees not subject to scab, has no other effect than that of cleaning them of moss, and for one season this cleaning process may be omitted without serious disadvantage. Arsenate of lead has advanced in price, but not greatly at present.

A Fortunate Scarcity.

Apparently bullfinches were killed off extensively by the severe winter of 1916-17, as hardly one has been seen on my place this season. Up to the end of January no Plum buds appear to have been eaten by birds, and this immunity may be attributed to the extreme scarcity of bullfinches.

Apples Rival and Barnack Beauty.

Being desirous of planting these two varieties of Apples somewhat extensively—if they are free growers and good fruiters, bear fruit of good quality, and are not subject to canker or scab—I should be greatly obliged by statements on these points by readers who have grown the two new varieties for some years. *Southern Grower*

The Week's Work.

THE KITCHEN GARDEN.

By F. Jordan, Gardener to Lieut.-Col. Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Celery.—The first sowing of Celery should be made at about this date. Choose a quick-maturing variety, not liable to run to seed, such as White Gem or Sandringham White. Sow in gentle heat and do not allow the plants to suffer from drought at the roots or to receive a check from any other cause until growth is completed.

Potatos.—A thorough change of seed is necessary to secure the best results with Potatos, and also much depends upon the care with which the tubers are selected and prepared. For "seed" purposes choose moderate-sized tubers and place them in shallow boxes or trays to sprout. Arrange the trays in a light, airy position in a place that is safe from frost, to encourage the development of strong, healthy sprouts. Examine tubers in store at short intervals after this date.

Horseradish.—To obtain long, straight roots of Horseradish it is necessary to make new beds from time to time. Dig the ground deeply and mix with it a liberal quantity of manure and decayed vegetable refuse. For planting choose straight, moderate-sized pieces of roots with crowns, and take away all side growths. Plant with an ordinary dibber in rows made 12 inches apart and allow a distance of 9 inches between the sets.

Mint and Tarragon.—Lift roots of Mint, place them in boxes, and force them gently in an early vinery or Peach house. Green Tarragon may be treated in a similar manner. The young shoots will soon be ready for use. Give the permanent beds of Tarragon a dressing of leaf-mould or manure from a spent Mushroom-bed.

Vegetable Marrow.—Sow a few seeds of such varieties of Vegetable Marrow as Epicure and Table Dainty in small pots to have plants in readiness for planting out in frames or growing in 12-inch pots for early supplies. The plants should receive no check to growth at any stage; endeavour to keep them strong and sturdy by careful attention to such details as watering and ventilating.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Oncidium.—Plants of winter-flowering Oncidiums, such as O. concolor, O. Forbesii, and O. varicosum should be kept on the dry side at the roots after passing out of flower, but give the roots sufficient moisture to keep the pseudo-bulbs plump. The plants will soon commence to grow afresh and any that require re-potting should be given attention as soon as new roots develop from the young growths. These Orchids are best grown in pans of just sufficient size to accommodate them, as the roots need a restricted space. The plants should be suspended from the roof-rafters in a house having a night temperature ranging from 52° to 55°, allowing it to rise to 60° or 62° as the season advances. A suitable rooting medium is a mixture of equal quantities of A1 fibre, half-decayed Oak leaves rubbed through a ½-inch sieve, and chopped Sphagnum-moss, adding sufficient crushed crocks to render the compost porous. Pot moderately firmly, and place the base of the young shoot well down in the compost in order that the new roots may soon grow into it. This minimises the danger of injury from slugs and wood lice, both pests being particularly fond of the young roots of Oncidiums. O. macranthum and O. lamelligerum are sending up their flower-spikes, which should be trained under the roof-glass or around sticks. When the flower-spikes have grown to a reasonable length pinch out the tips; this will make them branch, and the flowers will be finer.

The Cool House.—Odontoglossums, Odontiodas and their hybrids are in all stages of growth, and the greatest care should be exercised to ensure the new pseudo bulbs being well matured. The plants should be placed in full exposure to sunlight, short of subjecting the leaves to injury by scorching. Many of the plants will be near the completion of their season's growth, and about to send up flower-spikes. Great care should be taken to prevent injury by slugs, which are very destructive to the young, succulent flower-spikes. As soon as the inflorescence appears wrap a piece of wadding around the base of the leaf that shields the spike. This, whilst moderately dry, will prevent slugs from creeping up the stems. As the flower-spikes develop secure them to neat sticks, and place the plants on the stages facing the light, to cause the spikes to grow in an arching shape, thus adding to the beauty of the plants when in bloom. In even a small collection of Odontoglossums some of the plants will need repotting at intervals throughout the year. The bulk of the plants are generally repotted in August or September, but any that may require fresh rooting materials and are pushing forth young roots from the base of the current season's growth may be repotted at this period. For a few weeks after root disturbance little direct watering at the roots will be needed, provided the surroundings of the plants are kept moist. Plants of Odontoglossum grande and O. Insleayi leopardinum should still be resting, and will require little or no water until growth becomes active. If these plants are not allowed a long season of rest they will fail to flower in a satisfactory manner. O. citrosmum is on the point of starting into growth, but should be kept dry at the roots until the flower-spikes are seen pushing up through the centres of the young shoots, then the plants should be watered copiously and the atmosphere of the house more charged with moisture.

PLANTS UNDER GLASS.

By E. Harriss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Violets.—Whenever the weather is suitable, admit plenty of fresh air to Violets growing in frames, as a close atmosphere is conducive to damping. Look over the plants regularly, and remove decaying foliage. Well water the roots when necessary, and if a stimulant is needed sprinkle well-seasoned soot between the plants previous to watering, which should be done early in the day to permit of the foliage becoming dry before nightfall.

The Propagating House.—The propagating house and cases should be cleansed and the walls whitewashed in readiness for the season's work. Get ready the materials for making a hot-bed—Oak or Beech leaves well mixed with stable litter will provide suitable materials for the purpose. The leaves and dung should be thrown into a heap to ferment before placing them in the propagating frame.

Humea elegans.—Plants of Humea elegans will soon be ready for shifting into pots 8 inches in diameter, which are large enough for flowering size. Use plenty of material for drainage; many Humea plants fail through the soil becoming waterlogged. Use a light, open compost and pot firmly. When potted place the plants on a cool base in a light house near the roof-glass. If the roots were watered previous to potting further watering will not be necessary for several days afterwards. Shade the plants from direct sunshine and do not force them into flower by the use of much fire-heat.

Hydrangea hortensis.—Common Hydrangeas should receive attention and be repotted or top-dressed, as is necessary. Old plants should be well thinned of weak, useless shoots, retaining only those which promise to give good trusses of flowers. In repotting make the soil very firm. The compost should consist of a mixture of loam, leaf-mould, well-decayed horse-manure, lime rubble and sharp sand. Plants raised from cuttings rooted last year should be transferred to 5-inch pots. If the wood was well matured when the cuttings were rooted most of the plants should flower in the coming season. A portion

of the batch may be placed in a moderately warm glass-house for early flowering.

EUPHORBIA PULCHERRIMA.—When plants of Poinsettias (Euphorbia pulcherrima) have finished flowering they should be gradually dried off and the pots placed on their sides under the greenhouse stage for a few weeks. After that period they should be brought into a moist, warm house to produce suitable shoots for cuttings. Some of the more promising of the plants which were rooted last year should be selected for growing again next season. The stems should be cut down to within 1 foot of the roots, and when growth is active the balls of roots slightly reduced and repotted in 7-inch pots. These plants should produce three or four flowering shoots, and will be valuable for indoor decorations.

SALVIA SPLENDENS GRANDIFLORA. If cuttings of this Salvia are available a batch may be inserted. Dip the shoots in an insecticide, as red spider may be present on them. The cuttings may be dibbled rather thickly in pans or boxes filled with light, sandy compost. After watering the soil with lukewarm rainwater place the cuttings in a propagating case and keep them shaded from direct sunshine until they have rooted. Salvia Pitcheri may also be propagated now. When well grown this is one of the most beautiful of the autumn-flowering Salvias. The plants must not be coddled at any time, or the growths will become too weak to flower. Insert five or six cuttings in a 5-inch pot and place the latter under a hand-light in a cool house or pit. When well rooted transfer the cuttings to 7-inch pots and grow them in a cold frame, subsequently placing them out-of-doors for the summer.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

THE ALPINE STRAWBERRY.—Having cultivated the Alpine Strawberry for more than twenty years past, I am enabled to write very confidently in its favour as a most useful and highly appreciated addition to dessert fruits. Its use chiefly, in these gardens, has been as a dish for the breakfast table. By far the best method of cultivation is to raise plants each spring from seed. A few packets of seeds should be ordered now, not that there is any hurry to sow the seed, but the matter should not escape notice when the seed order is dispatched. At least four varieties are well worthy of cultivation, viz. Berger, a round, dark-red fruit; Belle de Meaux, a larger fruit and of a darker colour, often as dark as the well-known Waterloo; Rouge Améliore, or Improved Red, a long, tapering fruit of paler colouring; and Large Red Alpine, a fine type of the fruit, of similar shape to Rouge Améliore, and most prolific. My plan is to sow early in April and raise and cultivate the seedlings exactly as in the case of early Celery. In late, or backward districts, the sowing would be better made towards the end of February. The final planting need not be done before September, when a suitable plot of ground happens to be vacant. This is the Quatre Saisons, or Four Seasons Strawberry of the French gardens; it may be had in bearing from the third week in June until the first week in October. To accomplish this my practice is to allow the younger plants to crop for the first time in the autumn; these the following year will be the earliest batch.

ORCHARD TREES ON GRASS. Those who grow fruit trees in grass orchards should extend the circle of bare ground around each tree whilst the latter are still increasing in size. When increasing the circle fork up the soil lightly and remove any suckers or weeds that may be present. Next apply a light dressing of rich manure on the surface and bury it under the surface later by hoeing. The mulch should be applied every second or third year. Do not use animal manure if the trees are making an excessive amount of growth and not fruiting satisfactorily. In the case of dwarf Apple trees on the Paradise stock allow a circle of about 5 feet in diameter. For Pear trees on the Quince the circle should not exceed 4 feet, as a rule. For Plums somewhat less than this area will suffice.

ROOT-PRUNING OF ROBUST GROWING PLUMS.—Plums of the Reine Claude section, and the Transparent Gages, are strong growers, and wall trees may need root-pruning to bring them into a fruiting condition. As these Plums will possibly be occupying walls that have good aspects, the root-pruning needs to be done as soon as possible, and before any early crops are planted in the borders. It should not be done in too drastic a manner. If the trees are recently planted and the strength of the top growth indicates the presence of strong tap-roots, open up the soil and sever the tap-roots without disturbing the other roots more than is necessary. Checking excessive growth in this manner is preferable to hard pruning as the free use of the knife makes the plants susceptible to gumming or canker.

FRUITS UNDER GLASS.

By W. J. GUISE Gardener to Mrs DEMPSTER, Keele Hall, Newcastle, Staffordshire.

APRICOTS.—During the period of setting and stoning of the fruits of Apricots the house should be freely ventilated; the flavour of hot-house Apricots is vastly superior to those grown out-of-doors. Failure to obtain crops on pot trees, and established trees in borders, is generally the result of a close atmosphere, excessive fire-heat, or a lack of moisture at the roots. If the trees suffer from either of these causes the flowers will drop freely. When starting the trees into growth let the night temperature range from 40° to 45°, but the maximum degree must not be exceeded. The exceptional mild weather has hastened the development of the trees, the blossom-buds being on the point of bursting into flower. Up to the present we have used no fire-heat in the Apricot house. During the flowering period the hot-water valves will be opened just sufficiently to maintain a dry, buoyant atmosphere, which is essential to secure a good set. Admit a little air through the top ventilators at night. The flowers should be touched very lightly with a rabbit's tail at midday to pollinate them. When the fruits have set syringe the trees once or twice daily, according to the weather, with tepid water. Trees in pots and borders require abundant supplies of water during the growing season; neglect in this respect will cause the fruits to drop. Trees that are carrying heavy crops should be given liquid manure or other stimulants on frequent occasions. There is still time to plant fruit trees under glass, but the work should be done forthwith. Light, fibrous loam, mixed with mortar rubble or chalk, provides a suitable rooting medium, and sufficient should be used to make the border a good depth; efficient drainage is essential. Newly planted trees should be syringed and watered with extra care until the roots are established.

"MUSCAT" VINERY.—In starting the Muscat vinery let the night temperature be 55°. When the vines have started to grow freely increase the amount of warmth gradually to 70°. The day temperature may be allowed to reach 80° or a few degrees higher by sun-heat, but it is a mistake to exceed 70° by the use of fire-heat. Maintain a close, moist atmosphere to induce the buds to break freely. Always use water at the same temperature of the house when syringing the plants or damping the bare spaces. The house should be syringed and closed early in the day to create a moist atmosphere, and at the same time let there be a slight rise in the temperature. A dry atmosphere is necessary when the vines reach the flowering stage and until the flowers are fertilised. At forenoon, pollinate the flowers with a rabbit's tail or tap the trellis with sufficient force to disperse the pollen. To assist the setting of the fruit, allow the top ventilators to remain open a little at night. After the fruit has set, syringing should be discontinued, so far as the vines are concerned, but all bare spaces should be damped, the borders watered, and the house kept well charged with moisture, or red spider will prove troublesome.

GENERAL REMARKS.—The exceptionally mild weather experienced during the past fortnight has already had its effect on fruit trees under glass. The care bestowed in retarding growth, and the curtailment of forcing generally, appears to have been of little use. In any case a little fire-heat will be necessary at night to protect the opening flowers. Late Peaches and Nectarines are responding to the warm weather by swelling their buds. The tying of the shoots should be completed as soon as possible, or many of the buds may be broken off. Cherries, Plums and Apricots in cold houses are starting into growth, as if in defiance of one's wishes to keep the trees dormant for the present. Economise in fuel by closing the early houses soon after 2 p.m. and thus making the most of sun-heat. There should be no attempt to drive the fires for several hours later.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

LOBELIA.—The store plants of Lobelia compacta should be kept moist by sprinkling them frequently overhead. This treatment will favour the production of aerial roots, which again allows for the rapid propagation of every piece that can be removed for that purpose. When ready the cuttings should be dibbled closely together in ordinary cutting boxes. Stand the cutting boxes on hot-water pipes, where these are convenient for the purpose, and keep the cuttings excluded from the air by sheets of glass or paper. These will produce more cuttings, and in due time will form a thick mass of material, which needs only parting into pieces of a suitable size for planting when that time arrives.

ANTIRRHINUMS.—There is a good deal of labour attached to the raising of Snapdragons from seeds, including pricking off and transplanting. This can be obviated, and the plants still do well, by sowing thinly and afterwards thinning the seedlings to about 1½ inch apart, transferring them directly from the seed boxes to the flowering quarters. The plants should be spaced rather closer than usual, and, previous to planting, their roots be drawn through a mixture of loam and water, sufficiently thick to stick to them. If well treated in the preparatory stage the difference at first apparent will soon pass away.

TRIMMING BOX EDGINGS.—This is one of the uninteresting operations that is likely to be neglected in these pressing times, and it may even be beneficial to allow the plants to grow for a year untrimmed, following a season of drought or great heat, but as a rule it pays to trim them every year, and where the Box marks off flower-beds it is, of course, even more important that it should be cut than where it edges borders in the kitchen garden. Weather that put a stop to other work has permitted the clipping of Ivy, and now a similar opportunity is waiting to lightly trim all Box edgings. In these gardens they are all square-topped, and require to be carefully cut. Where the edgings are kept low and merely serve as dividing lines they are very expeditiously cut with a scythe. It may be noted that rough edgings when cut at this time of year are apt to get scared by frost, but it is seldom that this happens if the growth is slight, as it is when annually cut.

PRUNING DECIDUOUS PLANTS.—Young standards of such plants as Laburnum need to be cut back for the first few years after attaining the desired height of stem in order to obtain a stout, well-furnished head. Older plants should also be examined, and shoots that are seen to be of no advantage cut out. Some shrubs give more trouble than others—certain Crataegus require almost annual overhauling to keep them duly thinned. But all may be induced by careful pruning, which means the removal of weakly growth as a rule, to make rapid growth, and to form handsomer specimens than if left to nature.

MULCHING.—A mulching of cow-dung, placed over the roots of any plants that are in an unsatisfactory condition, is a valuable aid to growth. Rhododendrons, Azaleas, Picea nobilis, Ilex maderensis, Sciadopitys verticillata, and Quercus glauca are a few which respond very remarkably to this treatment. In the dressed grounds it is important to withdraw a portion of soil from above the roots, then to apply the mulch, which is covered with the soil formerly withdrawn.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENT FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 12—
Roy. Hort. Soc.'s Coms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.0.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, February 7, 10 a.m.; Bar. 29.9; temp. 50.3°. Weather—Dull.

Trees and Soil Sterility.

The well-known and much-debated fact that the soil beneath trees generally exerts an adverse effect on plant growth has been investigated recently,* with interesting results, by Mr. J. N. Sen.

The fact itself bears two aspects—one, that the shading, the drying, or other effect of the growing tree may interfere seriously with the growth of any other plant within the range of its shadow. The other aspect is more important, namely, that the tree as a result of its own growth sets up conditions in the soil which are adverse to plant growth: that the tree actually sterilises the soil.

Again, this sterilisation—if it occur—might be due to one of two causes. Either the roots of the tree rob the soil of so much mineral plant food as to impair its fertility; or the roots might excrete a poisonous substance (toxin), the presence of which in the soil hinders germination and growth.

The former view has often been put forward, but has never been verified experimentally. The latter view, as our readers are aware, has recently been promulgated by Mr. Spencer Pickering as the result of his experiments on the effect of one plant on another (see *Gard. Chron.*, Oct. 27, 1917, p. 170). To those familiar with the general facts of plant life, there is nothing à priori improbable in the toxin hypothesis. Among fungi, for example, it is common enough for the plant to excrete a poison sufficiently strong to kill the host plant. It was shown long ago that the parasitic fungus Botrytis cinerea, so destructive of Tulips and other plants, sets to work in this way, secreting oxalic acid, and thereby poisoning the tissues, through which it subsequently spreads.

At the same time there are difficulties in the way of accepting the toxin hypothesis in the case of the supposed sterility of the soil beneath trees, and in any case the first thing to do is to ascertain whether the soil owes its effect only to poverty or to the presence in it of some actively poisonous substance.

This Mr. Sen has done, and has found that the soil taken from beneath the trees (Tamarind) which he chose produced a strikingly inimical effect on the growth of seeds (Maize) planted therein. After two months the Maize seedlings in the "Tamarind" soil were poorly grown and sickly, whereas those sown at the same time in soil taken from neighbouring grass land were vigorous. Observations made in the open confirm the conclusion that, where vigorous tree-like growth has occurred, there the soil is barren. For example, a row of Bamboos was cut down and the soil brought under cultivation, with the result that where the Bamboos had been there growth was poor. Chemical analysis of the soil enabled Mr. Sen to throw new light upon these phenomena, for they showed that the soil taken from beneath the Tamarind tree contained an *excess of soluble salts such as sodium sulphate*, known to exercise a harmful effect on plant growth. The analyses also showed that the excess of salts was greatest in the surface layers of the soil, and decreased towards the deeper layers. Having established this interesting fact, Mr. Sen proceeded to offer suggestions as to how the accumulation of soluble noxious salts is brought about. He puts forward the view that the movement of such salts is related with the water-movement in the soil. The tree in its growth absorbs large quantities of water, and hence the soil in the neighbourhood of the roots is drier than that more distant. A movement of water tending to redress the balance takes place and the soluble salts are carried dissolved in the water, the water is taken in by the roots, and the soluble salts are left. It is possible, moreover, that the excess of soluble harmful salts is increased by the bleaching out of these substances from the fallen leaves and other débris; but of the two the water-movement already described appears to be the more important agent in effecting the accumulation of salts.

It is not easy to see how this simple explanation can apply to the case of grass and trees investigated by Mr. Spencer Pickering, and recently described in these columns; nevertheless, the possibility that Mr. Sen's observations provide the clue to Mr. Spencer Pickering's results must not be ignored.

* *Agric. Journ. of India*, July, 1917, reported in *Agric. News*, Barbados, Nov. 3, 1917.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting of the Surveyors' Institution will be held in the Lecture Hall of the Institution on Monday, the 25th inst., when a paper, on "The Effect of Taxation on the Development of Mineral Estates," will be read by Captain (late Professor) DAVID BOWEN, R.E. The chair will be taken at 5 o'clock.

CLASSIFICATION OF THE PRIMULAS OF THE PETIOLARIS-SONCHIFOLIA SECTION.—Mr. W. G. CRAIB is known in the Primula world as a keen student of the genus Primula, and especially of the section typified in his classification by P. petiolaris and P. sonchifolia. He has now published a further contribution to the subject in *Notes from the Royal Botanic Garden, Edinburgh*, January, 1917, pp. 249-277, based on the Calcutta, Edinburgh, and Kew Herbarium specimens. Eleven species are described as new, and the section as it now stands comprises 25 species. The enumeration is preceded by an historical sketch, by a discussion of the grouping according to affinities, and by a key to the species. The key is based primarily on characters offered by the leaves, supplemented by modifications of the flowers, their calyx, and their corolla. Synonymy and geography are given in the enumeration, as well as altitudes. Practically all the species occur at elevations of 10,000 feet and upwards, and no fewer than 15 are recorded from 12,000 to 15,000 feet, while the greatest elevation given is 5,000 metres—about 16,400 feet. This section of Primula is wholly Indo-Chinese.

PLANTS OF COLOMBIA.—Mr. H. PITTIER'S sixth contribution on "New or Noteworthy Plants from Colombia and Central America" includes a number of Moraceae—two species of Coussapoa, and four of Cecropia. Of Roupala, the northernmost type of the Proteaceae in the New World, three new species are described. Roupala extends as far north as Mexico. It is closely allied to the Australian and Asiatic genus Helicia, which reaches temperate regions in Eastern Asia. Among other novelties are several species of arborescent Caesalpiniae; nearly a dozen species of Combretum, and half a dozen of Cordia and as many of Bignoniaceae.

AMERICAN ANEMONES.—In *Rhodora* for 1917, Mr. M. L. FERNALD describes some colour "forms" of American Anemones. Anemone riparia, a species closely allied to A. virginiana, presents three variations, namely: the ordinary white condition; rhodantha, with red flowers, and inconspicua, with thick, leathery, greenish or greenish-white sepals. A. virginiana has usually greenish-yellow flowers, and the variety leucosepala, white flowers. A. multifida offers several variations, both in colour and number of sepals. A. m. sanguinea bears flowers of a bright red, whilst those of A. m. lencantha are of a pure white. The usual number of sepals is five, but in the variety polysepala they are 14-16 in number, and bright red in colour. These are all relatively small-flowered species.

VITIS NOVAE-ANGLIAE.—Vitis novae-angliae is the name given by Mr. FERNALD to a New England vine, which has hitherto been regarded as a hybrid between Vitis Labrusca and V. vulpina. Although this vine is in many ways intermediate between the two species named, the author gives good reasons for raising it to specific rank.

THE GENUS ATHYRIUM.—*Rhodora* for September, 1917, contains an interesting article by F. K. BUTTERS on the genus Athyrium and the North American Ferns allied to A. Filix-foemina. It is illustrated by figures in the text, and the species of Athyrium described and discussed are A. asplenioides and A. angustum, with numerous varieties of the latter.

BASKET-MAKING BY SOLDIERS.—A scheme for the training of disabled soldiers in basket-making has been organised jointly by the Ministry of Pensions, the Ministry of Labour, and the Food Production Department. The financial arrangements are in the hands of the Ministry of Pensions, which will defray the cost of training and the capital expenditure involved in the workshops. The Food Production Department will supply an organiser for the scheme,

sel... and treat with the ... al War Pensions Committees and gene...lly assist in bringing together the tru...al wors... who are suffering from a shortage of baskets, and the basket works.

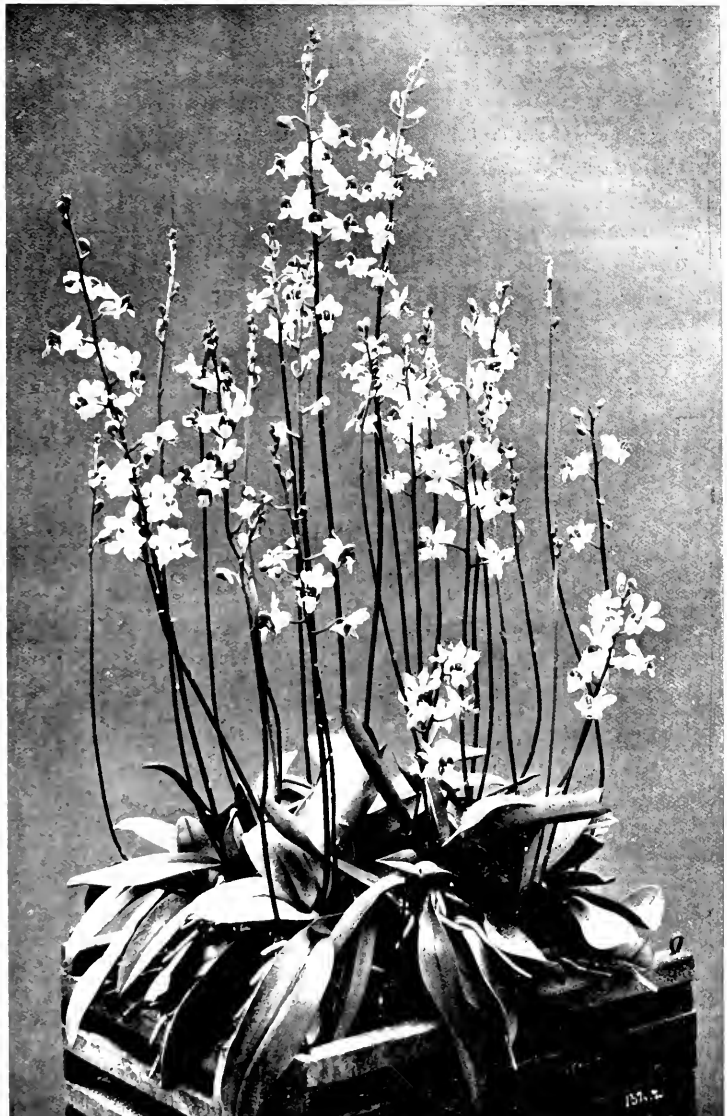
CLUB FOR WOMEN LANDWORKERS.—A clubhouse for members of the Women's Farm and Garden Union and the Women's National Land Service Corps has been opened at 51, Upper Baker Street, in a house adjoining the offices for both societies. Bedrooms are available for the use of country members.

WAR ITEMS.—2nd Lieutenant HUGH COLVIN, of the Cheshire Regiment, has lately received the V.C. for conspicuous bravery in the field, and has received a hearty welcome at Chester, which he visited on his return home. Mr. COLVIN'S father is head gardener at Rose Bank, West Didsbury, and his son entered the gardening profession at an early age, being employed as an apprentice by Lady STOREY in her gardens near Lancaster. Later, however, he lived in Belfast, and enlisted there in 1906 in the 8th Royal Irish Hussars. He served for six years in India, and went to France in December, 1914, obtaining his commission in April, 1917.

—— Pte. C. PASCOE, late inside foreman at the Friary Gardens, Old Windsor, was awarded the D.C.M. for gallantry in bringing in wounded on September 2, 1917, from the front line under fire. Pte. PASCOE joined the Royal Berks in January, 1916, afterwards being transferred to the 17th Manchester Regiment as stretcher-bearer. Twelve men from the Friary gardens are serving in France and Siberia. One has been killed and several wounded.

THE FERTILISING RAIN. The philosophy of TOLSTOY'S remark that "the property of rain is to wet," does not, according to the most recent investigations,* suffice to explain the beneficent action of showers on the growth of plants. Long ago it was suggested that rain was an important purveyor of nitrogen to the soil, but measurements show that the amount of combined nitrogen brought down by rain is almost negligible—a mere 4 or 5 pounds per acre per annum. Recent experiments indicate that the favourable influence exercised on crops by rain is to be ascribed not only to the moistening but also to the aeration of the soil. For rain is a saturated solution of oxygen. In support of this view it is found by RUSSELL and APPLEYARD that when the course of the bio-chemical activities of the soil is followed they do not run exactly parallel with the fluctuations of moisture-content as might have been expected. But when a comparison is made between the changes in the rate of bio-chemical activity on the one hand and the rainfall on the other a closer agreement is observed. It therefore seems probable that the hastening of soil decomposition with the resultant liberation of plant food, and the more vigorous growth of roots are to be ascribed only in part to the water of the rain, and the other virtue of the rain lies in the fact of wetting it is to air. Oxygen brought in solution to the roots is undoubtedly oxidizing, root action is stimulated, and the plant flourishes more vigorously. Mr. WATSON may find herein a clue to the cause of deterioration of greenhouse soils to which he refers on p. 52.

THE GENUS MAHONIA IN THE OLD WORLD.—To the January 1917 number of the *Edinburgh Notes*, Dr. H. TAKEDA contributes a synopsis of the Old World species of Mahonia, as distinguished from Berberis. There is a large number of previously undescribed Chinese species. Ten species are recorded from India, whereof seven are here first defined; but several of these have been raised from varietal to specific rank. Including five species not seen by this author, 25 species are now known to inhabit China; two-thirds of these have been published since the appearance of FORBES and HEMSLEY'S *Enumeration of Chinese Plants*, and Dr. TAKEDA makes considerable emendations in the synonymy of previous writers on the genus. The first record of these species was made by ROBERT FORTUNE, who discovered M. Fortunei and M. Bealei; the former was published by LINDLEY in 1846, and the latter by FORTUNE himself in the *Gardeners' Chronicle* of April 12, 1851, p. 212, both under Berberis. In addition to the Indian and Chinese species there are three or four in Formosa, and one each in Malacca, Annam, Siam, Java, Burma, and the Philippine Islands; in most cases the species are endemic. It will come as a surprise to many readers that no species is a native of Japan. M. japonica and M. Bealei are both cultivated in that country, as well as in this; but these very distinct plants have been much confused in literature and cultivation. The author states that "these two species may show some resemblance in foliage under abnormal circumstances, yet an absolute distinction can always be seen in the inflorescences. While M. Bealei



[Photograph by F. J. Wallis.

FIG. 25.—BORITIS PULCHERRIMA: COLOUR OF FLOWERS VARIES FROM PURE WHITE TO CRIMSON. (See p. 58.)

has racemes rather straight, stout, and densely beset with small bracts; those of M. japonica are rather slender, straggling, and loosely furnished with large ovate bracts; and the flowers of these two species are totally different." Dr. TAKEDA'S excellent paper is to be illustrated by 37 plates, but the plates were not ready for issue with the letterpress.

* Russell and Appleyard, *Journ. Agric. Sci.*, III., Pt. 3, p. 285.

THE CANNING OF FRUIT AND VEGETABLES IN AMERICA.—The active propaganda carried on in America to increase the canning of fruit and vegetables has, according to *Gardening*,* proved remarkably successful, and as a result our contemporary states that there are "one billion cans of home-canned fruit and vegetables on the pantry shelves of American houses." It adds with justice, and in view of the need for preserving food, that they are the most important collection of cans the world has ever seen.

LOCAL SOCIETIES.—The eighteenth annual meeting of the Croydon Horticultural Society was held on January 15, Mr. A. ALDERMAN in the chair. A report of the year's work was read by the secretary, including the financial statement, which showed that the Society held a credit balance of over £50. The president (the Mayor of Croydon), the chairman, Mr. A. ALDERMAN, and the other officials of the Society were re-elected.

—— The Lewisham Horticultural Society's annual meeting was held on January 21. It was reported that the membership is 1,100, and the members hold 81 acres in allotments. The financial statement showed a cash balance of £266. Mr. H. J. JONES, the chairman, was re-elected, and Mr. W. PAYNE was appointed secretary, in place of Mr. WEBBER, who resigned.

—— The ninth annual meeting of the Watford Horticultural Society took place on January 23, the Rev. W. HARTLEY PARKER in the chair. The report of the year's work was read, and the financial balance was stated to be nearly £20. The Earl of CLARENDON was re-elected president, Mr. F. J. McLEES was again appointed hon. secretary, and the other officials were duly elected.

—— The annual report of the Chester Paxton Society has been received, and gives an account of much useful local work. The Society has given assistance to allotment-holders, including the publication of a helpful pamphlet on the growing of vegetables, and the donation of a number of prizes and cultural certificates for the best allotments.

PUBLICATIONS RECEIVED.—***The Seed Trade Buyer's Guide.*** *(The Seed World,* Chicago, Ill.) Price $1.00.—***Experiments with Potatos at R.H.S. Gardens, Wisley, 1917.*** Reprinted from the *Journal of the R.H.S.*, Vol. XLIII. (London: Spottiswoode, Ballantyne & Co., Ltd.)

DORITIS PULCHERRIMA.

THE story of this pretty little Orchid (see fig. 25) was recently told in the *Orchid Review* by Mr. Rolfe. The plant has been grown in quantity at Kew for years, as the result of a cheap lot of imported plants purchased in Messrs. Protheroe and Morris's Auction Rooms. It was formerly called Phalaenopsis Esmeralda by Reichenbach, who ought to have known better, for it is not in the least like a Phalaenopsis. He described it in 1874 as a lovely gem with spikes of amethyst-coloured blossoms, which had been introduced from Cochin China by M. Godefroy Leboeuf, who found it growing on isolated rocks in the midst of a small thicket of Conifers, never on trees. The plant is very easy to cultivate, so easy that it might be used as a bedding plant if it would stand our summer climate. Free flowering, with spikes erect, the flowers keep fresh for weeks, whilst the plant never gets out of condition. The flowers vary in colour from crimson to lilac and almost pure white. These colour variations deceived Reichenbach, who named one of them Phalaenopsis antennifera, another P. Regnieriana, and a third P. Buyssoniana. W. W.

* *Gardening*, Jan. 1, 1918.

ON INCREASED FOOD PRODUCTION.

THE VALUE OF RABBITS.

AT the present time, when flesh food is dear and scarce, no garden of half an acre or more should be without a few rabbits, even if other stock is kept, for rabbits will eat quantities of stuff which no other stock will eat. They outclass pigs altogether for consuming garden refuse. They will eat almost anything herbaceous, including the stalks of Brassica plants and Jerusalem Artichokes, fruit-tree prunings, fence clippings, and much of the dry garden litter which is usually collected for bedding. Apart from the flesh food produced, the value of the manure obtained is worth consideration.

No special variety need be kept. Perhaps a Dutch doe crossed is as good as any for the purpose. One doe will often be sufficient, but if two are kept they should be timed to kindle about the same time, so that the young can be run and dealt with together. Alternate lots of young may be sold early if space and food are not available. A buck need not be kept, as it can easily be borrowed, and the young bucks should be killed when half grown if space is not available for their separation. The doe should be kept in any large, plain box, with a wire door in front. The young, when six weeks old, should be run on a large floor, such as that of a tool house or old carriage house, where they can get exercise and be easily fed with garden refuse.

They eat a surprising quantity of green food, and therefore it is important that a number should not be kept in excess of the food available. There is most garden refuse in the autumn. For convenience, when there is no garden refuse, a small plot of Chicory, Lucerne, or Thousand-headed Kale should be grown. Very little bought food should be afforded at present prices. A little bran and linseed or other cake may be given dry to counteract effects of much green food. *T. T. Taylor.*

ONIONS.

No vegetable crop is more remunerative than a well-cultivated plot of Onions. Rich soil and deep cultivation are necessary to grow good bulbs, and it has been proved that the best results are obtained, and especially in districts where the ground is cold and heavy, by sowing the seeds thinly in boxes of finely-sifted, rich soil about the first week in February. It is often a difficult matter to get the soil in the open in a suitable condition for a seed-bed before the season is too far advanced, whilst seeds sown in cold, damp ground are a long time before they germinate, and give only weak plants. The seeds should not be germinated in a high temperature, and the seedlings should be ready for transplanting early in April.

In favourable districts the main crop of Onions should be sown as early in March as the condition of the soil permits, and although the ground may have been trenched in the autumn, very careful preparation of the soil is necessary. The work should be done at the first favourable opportunity by forking the surface of the bed and breaking the soil as fine as possible. When the time for sowing arrives, and the ground is dry enough to crumble under the foot, the bed should be carefully trodden and raked evenly on the surface before the drills are drawn. The drills cannot be too shallow, provided the soil is fine enough to cover the seeds. When the soil is not thoroughly pulverised it is a difficult matter to draw the drills as evenly as is necessary, and many of the seeds being buried too deeply produce plants that give thick-necked Onions. When the seeds have been sown and covered with the soil, press the rake carefully and lightly over the surface, which should afterwards be rolled. If the seeds are sown sparingly very little thinning will be necessary if the bulbs are intended for ordinary use, but if large bulbs are desired the plants in a portion of the bed should be thinned to 6 or 8 inches apart. As soon as the plants are well through the ground hoe the surface lightly in order to destroy small weeds, but do not hoe deeply, as the soundest and best-shaped bulbs grow on a firm surface. Frequent dustings of soot and lime will do much to promote healthy growth and keep the Onion maggot in check.

If suitable varieties are selected sound bulbs may be harvested in July from plants raised in the previous autumn. We have a quantity of bulbs of the variety Long Keeper still in good condition from plants sown in August, 1916, and harvested in the following July. Wroxton Globe is another good Onion for autumn sowing. Transplant the autumn-raised seedlings in rich soil as soon as the ground is dry enough in spring. The ground for autumn-sown Onions should be prepared in the same manner as for spring Onions. *J. Dunn.*

CORN INSTEAD OF RHUBARB.

MAJOR DENT, Chairman of the West Riding Executive Committee, recently convoked a conference of the Rhubarb growers in the Leeds district to consider what portion, if any, of their market gardens could advantageously be ploughed this spring for the production of corn crops. About 3,000 acres around Leeds are devoted to Rhubarb growing, and in the past two years the disposal of the produce has presented some difficulty owing to the lack of transport, the high price of fuel and labour, and the shortage of sugar. It was suggested that 1,000 acres could be spared for the growing of more essential food crops this year; and the conference passed a resolution "that in the national interest the 1914 area of Rhubarb land should be reduced by one-third in 1918." A committee of five growers is now engaged on an inspection of the ground with a view to the ploughing of the oldest and least healthy portions of the stools. It is hoped to devote 2,000 more acres this year than last within the County Borough of Leeds to the growing of necessary food crops.

TOMATOS.

A SOWING of Tomato seed should be made now, and the seed germinated in a house where the temperature is kept steadily at 55°. There are many things to guard against in Tomato growing at this season. Do not pot the plants in a cold shed. A temporary potting bench should be erected in the Tomato house itself to prevent the plants receiving checks through a sudden lowering of the temperature by the frequent opening of doors. The use of cold, wet soil for potting is harmful, and other points to observe are not to pot the seedlings too firmly, and to use warm water for watering. For seedlings thumb-pots are large enough. The compost should consist of leaf-mould and coarse sand, and should be warmed before it is used. Place the plants in the soil up to the seed-leaves, and grow them near the roof-glass. Later the plants should be shifted into 3-inch or 6-inch pots, adding fibrous loam to the compost, and making the soil firmer than at the first potting. Place a neat stake to each plant. Water the roots very carefully, and ventilate the house when the weather is favourable. For the final potting I use 10-inch pots, and for soil equal parts of loam, coarse sand, or mortar rubble and old Mushroom-bed manure. Do not damp the floor and staging to excess, as a saturated atmosphere is harmful. Ventilate freely, but not to such an extent as to cause a sudden fall in the temperature. When a number of trusses are set give the roots stimulants freely. Nothing is gained by leaving the fruits on the plants to ripen; when turning colour they should be gathered and placed in a warm, dry place to complete their ripening. *C. Davis, Holy Wells Park Gardens, Ipswich.*

ARTIFICIALS FOR ALLOTMENTS.

ALLOTMENT holders who require artificial manure and have difficulty in obtaining supplies

locally should communicate at once with one of the agents recognised by the County Agricultural Executive Committees and the Food Production Department for the sale of artificial fertilisers. Lists of agents for each county may be obtained on application to the County Agricultural Executive Committee, or to the Food Production Department, 72, Victoria Street, London, S.W. 1.

In order to obtain the most favourable terms allotment holders should combine to place large orders. The advantage of doing so may be illustrated by the prices which have been fixed for sulphate of ammonia when purchased between January and May of this year: For 2 cwt. and less than 1 ton, 18s. per cwt.; for 1 cwt. and less than 2 cwt., 19s. per cwt.; for quantities not less than 28 lbs. and less than 1 cwt., 21s. per cwt. Prices for superphosphate and basic slag may be obtained from the agents.

VEGETABLES AT KEW.

DURING 1917 vegetables were grown in considerable quantities in the nurseries at Kew Gardens, and some of the flower beds were planted with vegetables having more or less ornamental foliage, such as Beet, Kohl Rabi, Carrot, Chinese Cabbage, Couve Tronchuda (Portugal Cabbage), and Kales. In the coming season an increased area will be cropped with vegetables. The illustration in fig. 26 shows the ploughing up of the large open lawns in front of Kew Palace, which it is proposed to plant with Potato British Queen. Women gardeners have cleared the Violas, Iberises, Phloxes, and other spring flowers from the beds in front of the Palm House, and are trenching the ground preparatory to planting Onions, the young plants for the purpose having been raised under glass. This portion of the flower garden is about half an acre in extent. Still more of the nursery beds devoted in pre-war days to the growing of Tulip and Daffodil bulbs, Polyanthus, Aubrietia, Iberis, and the hundred and one things required to furnish the flower garden, beds, and borders, have recently been cleared to grow larger supplies than last year of Parsnips, Carrots, Leeks, Turnips, Cauliflowers, Cabbages and Potatos. Two large beds planted last autumn with Cabbage Harbinger look very promising.

The outbreak of the war has impeded the development of the new Pathological Department, and a considerable portion of the ground set aside for experimental purposes is in the meantime let in 20, 10, and 5 rod allotments to the garden employees.

FOOD EXHIBITION AT THE INSTITUTE OF HYGIENE.

AN exhibition to encourage food production was held in the Institute of Hygiene, 34, Devonshire Street, London, W., during the week ending February 2. Vegetable foods formed a large part of the exhibition, and there were shown nutritious dishes made from Nuts, uncommon cereals, Pine kernels, and Beans. Experts gave demonstrations in the preserving of fruits and vegetables by bottling and drying, and methods of cooking.

The Royal Horticultural Society showed a series of lantern slides illustrating vegetable and fruit production and soil management, garden tools, seed testing, Potato storage, greening and sprouting of seed Potatos, fertilisers, the Wisley Turnip Flea beetle trap, and a large series of Haricot Beans grown at Wisley.

FIG. 26. PLOUGHING THE PALACE LAWN AT KEW FOR CROPPING WITH POTATOS. *[Photograph by E. J. Wallis.*

HARICOT BEANS.

I HAVE threshed the remainder of the Beans I grew last season for use as Haricots (see *Gard. Chron.*, Dec. 1, 1917, p. 216). I have another variety, The Princess of Wales, a French climber, that may be recommended both for quality and cropping. In fact, the quality, when cooked as a Haricot, is not inferior to that of the Dutch Brown.

Last season, when planting late Potatos, the space of one Potato row was missed in the centre of the plot. This area was marked at each end by a peg, and about the second week in May and before the Potatos were through the soil, a pint of seed of Princess of Wales Bean was sown therein. The Bean sticks were placed in position immediately and the seeds were covered with soil, thus obviating trampling between the Potato rows afterwards. The Bean row and Potato rows ran north and south, and when the Beans were fully grown they cast but little shade on the Potatos. The growth of this French climber is not so strong as the ordinary Scarlet Runner, and Pea sticks were suitable as supports. The row of Beans was 26 yards long, and the plants gave 25 pints of excellent Beans.

There seems one slight disadvantage with this French climber, in that it requires sticks for support; but the pods ripen on the sticks, whereas a drying-shed is required to ripen the dwarf kinds.

I am unable to say what the average weight of tubers would have been from a row of Potatos 26 yards long, but I think the 25 pints of Beans would represent more in food value than the produce of the row of Potatos, and there is not the least doubt but that this simple method of growing Haricot Beans amongst late Potatos would well repay cottagers and allotment holders.

The following is a recipe for cooking Haricot Beans: The day previous to cooking, place the required quantity of Beans in a basin; sprinkle them with a small amount of bicarbonate of soda, and then fill the basin with boiling water; cover with a plate and leave to soak for about 16 hours. Just before they are cooked rinse the Beans with cold water. When the Beans are in the saucepan cover with cold water and simmer for 1½ hour. As evaporation takes place add boiling water at intervals. A little bacon rind cooked with the Beans improves their flavour. *G. H. H. W.*

GROUND OPERATIONS.

IN reply to Mr. Bartlett (p. 18), my belief is that digging light ground four or five months before the time for planting or sowing might cause it to lose much of the humus and other plant foods present, as well as destroy beneficial bacteria, and favour the increase of harmful ones. I, too, use old manure—six to twelve months old—at planting time. Gardeners are "opportunists"; it is not wise to be dogmatic in all operations, nor wise to have all our eggs in one basket. What may seem a contradiction may be only a difference of conditions.

Mr Beckett is quite correct, as he has studied his kind of soil, and found out by experience the best way of dealing with it. One great point in Mr Beckett's favour is that clay soil freshly dug keeps wet longer, and is colder in the spring, with the result that bacteria are later in starting their good work. *Japonica.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

WALL FRUIT TREES (see p. 45). In his remarks on cordon fruit trees, *A. C.* states: "No cordon Pear or Apple tree needs more than a barrowful of soil," and yet they should be "planted 3 or 4 feet apart. It is not wise to plant them closer, as, where very close planting occurs, the roots interfere with each other." Supposing we place the trees at his minimum distance, 3 feet, allowing the soil to be 2 feet deep and 3 feet wide, we have 18 cubic feet of soil, which it would take a rather large barrow to hold. The lower spurs are to spread 6 to 9 inches on either side of the stem, and "shorter, lighter, and further apart as they ascend; the sap will be evenly apportioned, and every part of the tree bear fruits of even size and quality." If the stems are given an inclination of 45° it is difficult to understand how the sap will be evenly apportioned on the two sides of the stem. "No tree was ever planted too high; the best examples of high planting are the millions of fine trees on the raised banks of British hedgerows." It is true some fine trees are to be seen in such positions where they are, or have been, fed by the water in the ditches, but still finer specimens are to be found on comparatively level ground in some of our parks. I can point to some which measure 30 to 45 feet in circumference. As to saying that no tree was ever planted too high, there is ample proof, in most of the southern counties, that no fruit tree ever gets half enough water in an ordinary season, or why do they succeed doubly as well when amply supplied with moisture. As to waiting till April, this is one of the worst months to plant deciduous trees. I would not choose August, but would rather plant in that month than in April, and sprinkle whitening and water over the leaves to check transpiration. During such a winter as the present, with the exception of a week or two, planting could be done with more certainty of success than in the spring. *A. C.* rightly says: "A tree does best planted when it may move in the roots and not in the head." This object is best attained when the transplanting takes place immediately after the primary leaves have commenced to change colour in the autumn, supposing no late green growth has been allowed to form. "The stronger a tree, the more it should be inclined from the upright line." Are not strong growing varieties, when well managed, also correspondingly strong at the base? And in planting a border must we leave out the strong growers, which in some cases may happen to be desirable ones, in order to keep to the angle of 45°? If cordons are to be planted, I should prefer not to lean them to the right or left; leaning the top back to the wall is another matter which I will not now discuss, and certainly I would not have half the wall bare, as it must be under *A. C.'s* plan. I also entirely disagree with winter and early spring mulching. *Wm. Taylor.*

CONIFERS AT DROPMORE DAMAGED BY SNOW.—During the past three years the Conifers in these gardens have suffered much damage by unfavourable weather. The gale on March 28, 1916, ruined the beautiful Cedar avenue, last season much damage was done by storms to valuable trees, and now the recent snow has caused extensive damage to many fine specimens. A large tree of Cedrus atlantica in the pinetum is wrecked, and a fine old plant of Abies cephalonica has a huge limb torn off 50 feet in length and 6 feet 10 inches in girth, at the place where it joined the main trunk. In falling the limb stripped a fine Thuya dolabrata of its branches. Pines have suffered somewhat, but no damage has been done to any of the Douglas Firs, their weeping habit enabling them to rid themselves of much of the snow. *Chas. Page, Dropmore Gardens, Maidenhead.*

THE STORING OF APPLES (see pp. 8, 19, 29, 37).—Our fruit store is a large cellar under the house without either a window or ventilation except a slide in the door about 1 foot square, which I never close in the coldest of weather. The door faces due north, and the cellar is quite dark. It has shelves all around and a raised centre on which I keep Pears and dessert Apples. The bottom shelf is about 3 feet from the floor, and is used for storing Potatoes and other roots. Our Apple trees are mostly large specimens. Last year they bore very heavy crops, and the fruit was placed on the shelves more than a foot deep; indeed, some sorts were in layers 2 feet thick. They keep excellently well. We always get a good price for Apples in the spring on account of the firm, sound quality of the fruits. I have exhibited fruits of Annie Elizabeth at our local show on August Bank Holiday the following year after gathering. One of our varieties is named Baglan, but I cannot find the name in any list. It is a splendid Apple for making Apple moulds, the flesh, when cooked, being of a stiff nature. *J. T. Mason, Arden Hill Gardens, Altrincham.*

MEALY BUG ON VINES.—Noticing your remarks on Mealy Bug in the reply to *Constant Reader*, on p. 40 of your issue of January 26, I send you my experience in eradicating the pest. On taking charge of these gardens in January, 1912, I found the vines smothered with Mealy Bug. After pruning the vines the houses were thoroughly washed with Calvert's carbolic soap and boiling water, adding a wineglassful of paraffin to each bucketful. The vines were then scrubbed with very hot water, and afterwards scraped of all loose bark. Sheets of brown paper were laid underneath, and then burnt. The vines were afterwards thoroughly washed twice with Wood's nicotine soap and hot water, and, when dry, painted with a mixture of clay, nicotine, soft soap and sulphur, of the consistency of paint. The walls were given a coating of hot lime with paraffin added. After the vines had started into growth they were examined regularly once a week for Mealy Bug, and any that were detected destroyed with methylated spirit applied by a small paint brush. That season very few bugs were found, but the vines received the same treatment the following season, since when not a trace of Mealy Bug has been found. *J. M. Richards.*

"NOTES FROM A GALLOWAY GARDEN".—I should like to express through your columns the debt of gratitude your numerous readers owe to Sir Herbert Maxwell for his admirable series of "Notes from a Galloway Garden," so appreciative of the real beauty of the many subjects touched upon. There is perhaps no department of gardening of which the average gardener is so deficient in knowledge as that of trees and shrubs, with the result that in many pleasure grounds only the more common varieties of trees and shrubs are to be found. The notes regarding hardy border flowers and their grouping in herbaceous were equally valuable and delightful reading. *T. M. E.*

"DUG-OUTS" IN THE GARDEN (see pp. 24, 57).—Mr. Rowles states that I overlooked the fact that suitable conditions for the storing of fruit might be made. I quite agree this might be done, but the question of expense has deterred me several times from putting a concrete arch to my roof to keep out the drip, which will find its way through more or less, especially after heavy rains. These are not ideal conditions in which to keep either fruit or Potatos. For fruit it would be much cheaper and more satisfactory to build a proper fruit-room. I have grown several acres of field Potatos, and much prefer the old-fashioned pie, or well-made clamp, for the storing of all maincrop Potatos. I am glad this subject has aroused a little interest and discussion, which has brought to light the advantages and disadvantages of these underground stores. I have found my dug-out very useful. *W. Potts, Cirons Gardens, Leatherhead.*

BIRDS AND INSECTS.—To balance the good effect of the scarcity of birds, there is likely to be a plague of caterpillars this spring, judging by the Moths seen lately. Amongst others the Mottled Umber moth (Hybernia defoliaria) has been very plentiful. Although not of such painful interest to fruit-growers as the preceding, I may mention also that I caught four specimens in one night of the striking little "December Moth," which I had always considered rather uncommon until this season, whilst during late October and November that very pretty moth the Feathered Thorn (Himera pennaria), the caterpillar of which feeds on the Oak, was unusually plentiful. *T. E. Tomalin, Bessborough Gardens, Pitlochry, Iceland.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 29.—*Present:* Messrs. E. A. Bowles (in the chair), J. Fraser, W. C. Worsdell, W. Hales, J. Arkwright, and F. J. Chittenden (hon. sec.).

Potato Reproduction.—Mr. Arkwright showed a Potato of the 1916 crop, which, remaining unplanted, had continued to throw out shoots and produce small tubers. The tubers were successively absorbed and shrivelled as new ones were produced. The formation of young tubers from pith cells inside the old tuber, when the development of shoots is entirely suppressed, was referred to by Mr. Worsdell.

Hybrid Galanthus.—Mr. Bowles showed a number of seedlings raised by Mr. Chapman, of Rye, apparently the result of crossing Galanthus Whittallii with G. Fosteri, and showing characters of both parents in the foliage and to some extent in the flowers.

We give the following extracts from the Report of the Council, which will be presented at the one hundred and fourteenth annual general meeting of the Society, to be held in the Council Room, Vincent Square, at 3 p.m. on Tuesday, February 12, 1918.

THE REPORT OF THE COUNCIL.

In the beginning of the year the Government sought the Society's co-operation in still further organising the country and stirring it up to make an adequate effort to produce all the fruit and vegetables required for home consumption, and the Director-General of Food Production asked the Council to release Dr. Keeble, the director of the Society's gardens at Wisley, to take the head of the Horticultural Section of his Department, under a joint arrangement between that Department and the Society.

R.H.S. PANEL.

At the beginning of the year the Council set up a Panel of Expert Garden-Advisers, and nearly 2,000 names from all parts of the Kingdom are now inscribed upon it.

CONNECTION WITH THE GOVERNMENT.

In the summer a promise of a grant of money was received from the Treasury to assist in defraying the expenditure the Society was incurring on Government Food Production work. This enabled the Council to enlarge its efforts, and a Conference was held at Wisley towards the end of September. The Society's Special Representatives appointed by the Council to deliver lectures throughout the country during the winter 1917-18 were present at this Conference.

FOOD PRODUCTION PUBLICATIONS.

The Society's Food-Production Pamphlets and Leaflets have been of great help to the nation during the year. Since the war broke out approximately 500,000 pamphlets, diaries and leaflets concerning food growing and preserving have been issued by the Society.

REPRESENTATIONS MADE TO THE GOVERNMENT.

Throughout the year the Council have been keenly alive to the interests of horticulture in every direction, and representations have been made to Government Departments on the following matters: (a) Potato prices; (b) the provision of sugar for fruit preserving; (c) the release of tinplate for the making of fruit preserving cans and canning apparatus; (d) the provision of further allotment land and security of its tenure; (e) the preservation of valuable garden stock; (f) the exemption of necessary expert fruit growers from military service; (g) the offer of help in extending the cultivation of school gardens; (h) the importation of bulbs; (i) the carriage of plants; and (j) the need for speedy return of empties.

DUTCH BROWN BEANS.

Mrs. Lubouchere most kindly sent the Society samples of this Bean in 1915, and they were grown in a few private gardens, and also at Wis-

ley in 1916. The trials proved so satisfactory, and the quality as a food Bean so superior to anything of the kind which we had previously grown, that the consent of the Government was secured for a ton of the Beans to be imported last spring. They were widely distributed among the Fellows, and a certain quantity was grown at Wisley, from the produce of which a large stock has been secured. These will be distributed to the Fellows in March next, by the same organisation, and in exactly the same way as the surplus plants and seeds are always distributed.

LECTURES, &c.

The Society hopes to continue its food campaign unremittingly throughout 1918, and would be glad to increase it, if funds and staff permit. In this connection almost all the lectures arranged for 1918 are more or less directly connected with food production. A Potato lecture will be given in London at the Mansion House, at 3 p.m. on February 13, when the Lord Mayor will occupy the chair. A second will be held in Westminster, at the Caxton Hall, at 3 p.m. on Wednesday, June 19, at which the Rt. Hon. R. E. Prothero, President of the Board of Agriculture, has been asked to take the chair. Mr. W. Cuthbertson, V.M.H., J.P., will be the lecturer on both these occasions. The ordinary Fellows' tickets will not admit to these two lectures; special tickets can be obtained by applying to the Secretary of the Society, Vincent Square, Westminster.

GIFTS TO WAR HOSPITALS, CAMPS, &c.

The Society has sent out very large consignments of bulbs, seeds, and books, during the year, to the base hospitals and camps in France, and to the Prisoners of War Camp at Ruhleben. The thanks of the Society are particularly due to all who assisted by sending gifts for this purpose. The Society also provided the flower stall at the Albert Hall bazaar for St. Dunstan's Hostel in May, over which the Countess of Limerick kindly presided, many of the Fellows sending very large and valuable contributions.

WISLEY GARDENS.

The work at the Society's gardens has gone on uninterruptedly, though, of course, it has suffered very great inconvenience by the removal of almost the whole of the regular staff. In face of this fact the existing staff is greatly to be congratulated on the work accomplished. Some most useful trials have been conducted, particularly of wart-resistant varieties of Potatos. Reports on these trials will shortly be issued. A valuable exhibit of wart-resistant Potatos, with cooked specimens, with the same variety uncooked, was shown at the Society's fortnightly meeting on October 23, when it attracted much attention.

Experiments on the pruning and pollination of fruit trees are being continued, and numerous new crosses of vines, Strawberries, and Rubus are being grown.

The Society has made an offer to the Serbian Government to give free training in gardening to six young Serbians at Wisley, if the cost of their maintenance can be otherwise provided.

UNIVERSITY DEGREE IN HORTICULTURE.

The Council wish heartily to thank Sir Albert K. Rollit, Chairman of the Horticultural Education Committee of the Senate of the University of London, for the great interest he has shown in securing the institution by the University of a Degree in Horticulture. The Syllabus of Courses of Studies and Examinations will be found in the University Calendar for 1917.

REVISION OF PRITZEL'S INDEX.

The revision of Pritzel's Index has not escaped attention, and, as a first step, two Committees have been set up with a view of finding (a) the amount of information which those for whose benefit the revision will be mainly undertaken would wish the new Pritzel to include; and (b) the amount of information which those familiar with the preparation of works of this class consider that it may be possible to incorporate. By the aid of these Committees it is hoped to get matters in hand so as to be able to republish the work as soon after the war as possible.

WAR RELIEF FUND.

The work of the Society's War Relief Fund has made considerable progress during the year, but it has undergone a certain transition. As already stated above, the work falling on the Council and on the office staff had become more than they could accomplish. Accordingly an outlet was sought for distributing the work attendant upon the Fund by forming a new Committee and setting up a separate department for giving undivided attention to it. This was effected by appointing four members of the Council to act jointly with four members of the Ladies' Committee. The offices of the Fund are at present at No. 17, Victoria Street, Westminster.

OBITUARY.

It is with deep regret that the Council have to record the death of many Fellows, particularly the following: George Abbey, Elijah Ashworth, Lord Auckland, L. H. de B. Crawshay, C. T. Druery, V.M.H., Lieut. H. L. Foster, Alfred Hemsley, W. Marshall, V.M.H., Geo. Massey, V.M.H., Earl of Mount Edgcumbe, O. G. Orpen, Marchioness of Ripon, Chas. Ross, V.M.H., Leopold de Rothschild, Geo. Schneider, E. D. Till, William Thompson, Ph. de Vilmorin, and Walter Ware.

NEW V.M.H.

Owing to the death of five holders of the Victoria Medal of Honour, the Council have appointed the following gentlemen to this distinction, viz.: Mr. W. Jackson Bean, Mr. F. J. Chittenden, F.L.S., Sir Herbert Maxwell, Bart., F.R.S., D.C.L., LL.D., Dr. A. B. Rendle, F.R.S., F.L.S., and Sir Albert K. Rollit, D.C.L., LL.D., Litt.D.

NUMERICAL POSITION.

The following table shows the Society's position with regard to numerical strength during the past year:—

Deaths and Resignations	652
New Fellows	572
Numerical Loss	80
Total on December 31, 1916	13,911
Total on December 31, 1917	13,831

NATIONAL CHRYSANTHEMUM.

FEBRUARY 4.—Mr. Thomas Bevan presided at the annual meeting of this society, held at Carr's Restaurant, Strand, on Monday, the 4th inst. The Annual Report of the committee and Statement of Accounts had been circulated among the members, and were therefore taken as read. The report referred to the work of the society during 1917, including that of the Floral Committee, in connection with new varieties submitted for award. The accounts showed a credit balance of about £17. Sir Albert Kaye Rollit was re-elected president; Mr. Thomas Bevan, chairman of the executive committee; Mr. E. F. Hawes, vice-chairman; Mr. John Green, treasurer; Mr. C. Harman Payne, hon. foreign corresponding secretary; and Mr. C. H. Curtis, general secretary. The whole of the retiring members of the committee were re-elected, and Mr. H. J. Jones was elected in the place of the late Mr. E. Such. Following the formal business of the meeting, the chairman presented a testimonial to the late secretary, Mr. Richard A. Witty. The presentation consisted of an illuminated address and a clock. Several members spoke in appreciation of the services Mr. Witty had rendered, and Mr. Witty suitably acknowledged the gifts.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JANUARY 14. The monthly meeting of this Society was held in the R.H.S. Hall on Monday, the 14th ult. Mr. A. Bedford presided. Four new members were elected. Two members withdrew interest from their deposit accounts amounting to £7 0s. 4d. The sum of £61 18s. 9d. was passed for payment to the respective nominees of deceased members. The sick pay for the month on the ordinary side was £77 5s. 8d., State Section £34, and maternity benefits £10 10s.

CROPS AND STOCK ON THE HOME FARM.

BARLEY.

WHERE the land is specially suitable, and the season favourable, Barley forms one of the most profitable farm crops. The Government price of 65s. per quarter for malting samples cannot but be remunerative when we consider that even a fair crop of five quarters per acre is easily produced, and at this low estimate means a gross return of £17 per acre.

Barley can be grown on shallow soil overlying chalk, as the roots do not penetrate so deeply as those of Wheat. The roots of Barley not only start from the seed, but also adventitiously from the lower part of the stem, just below the soil.

Barley tillers more freely than Oats. If on the farm there is a choice of soil, then choose for Barley that which is light in texture and naturally drained, for example, that overlying chalk, and one in which Turnips are grown and fed off by sheep. Such stimulative foods as sheep droppings are all in favour of the Barley crop, provided, of course, this is not excessive from a too liberal allowance of cake or previous manuring for the preceding crop. If the soil is too rich the quality of the Barley is deteriorated, and there is considerable risk of the crop being lodged by heavy rains and winds as the ripening stage approaches. If the land is clean, as it should be, a good crop for Barley to follow is Wheat, provided the land for this cereal is in good heart. Good quality Barley may be expected even if the soil is not altogether thin, but of a calcareous nature.

A Clover ley is a good preparation if the ploughing and pressing were done in the early winter to enable a good tilth to be obtained at sowing time. This preparation is not always available, and does not admit of a second ploughing in spring, which is considered necessary for a good tillage for this crop, and especially if the surface soil is of an adhesive, cold, and unkind character.

An ideal preparation would be sheep fed Turnips during dry weather in November and December, ploughed at once 4 inches deep and again ploughed twice if possible previous to sowing, and given plenty of "work" to ensure a fine surface and a good tilth.

The autumn ploughing of Wheat stubble ensures such a preparation, as the pulverising effect of winter frost and wind on the surface would be assured, and, if dry weather ensued in February, then plough and cultivate well to disintegrate all particles of Couch, should this weed be present, thus bringing it to the surface to be picked off and burnt.

How the seed should be sown varies according to circumstances. Drilling is the best method, as the seed is deposited at a uniform depth, thus ensuring an even and regular germination and future growth. Consequently the ripening process is simultaneous. This is highly important, as where the ripening is unequal the quality of the Barley is uneven, and the later ripened ears dilute the superior or earlier ripened corn, which is fatal to a good sale.

Broadcasting the seed, or even sowing with a Massey Harris cultivator, although more expeditious, does not commit the seed at such an even depth, and this is in many instances the cause of the crop being, to use a local term, "hedge grown," which means that the crop contains both ripe and green ears.

March is a good time to sow if the "season" land in good working order is assured. Early in April is not too late in the Southern Counties provided the weather is favourable to growth during May and June. Early-sown Barley as a general rule produces superior corn, and the ripening is more uniform.

In some districts drilling is done in February, and even in January, but this should only be in favourable situations, where late spring frosts are not common, as the growth is liable to be checked, which cannot but be detrimental, as irregular growth is not conducive to success.

The quantity of seed sown per acre varies in districts; as a rule three bushels are sufficient, as the tillering properties are greater than in Oats.

The application of stimulants during the growing stage requires much thought and judgment; much depends on the soil and the previous crop. Too much manure is injurious, while too

little results in a defective yield of both straw and corn; also in the quality, which is important. Although March and the early part of April is considered to be a good general time to sow, good crops have resulted from May sowings, but this can only be by the aid of showery weather and bright sun from then onwards through June and July. I merely mention this to show those who cannot sow earlier for various reasons that it is still possible to obtain a reasonable crop, but not of the highest quality, by sowing late.

With Wheat and Oats a complete change of seed is beneficial, but in the case of Barley it is not so imperative, as when a particular variety proves satisfactory the same strain of seed may be employed successfully for several years on the same farm.

In some cases, where Barley is desired, and there is little choice of land, some stimulant may be necessary. For instance, if the Turnips or Swedes grown as the previous crop were carted off for store-fed cattle, then the land under such conditions would need manuring.

When preparing the soil for the seed, sow evenly over every acre 3 cwt. of superphosphate, and when the Barley is well through the soil add 1 cwt. of sulphate of ammonia per acre, which will give a fillip to growth.

The following are desirable varieties:

Chevalier.- The most popular of all Barleys, introduced by the Rev. D. Chevalier in 1830. A well-grown ear produces sixteen grains on each side of the rachis.

Hallett's Pedigree Chevalier.—Selected by the late Major Hallett in 1861. A prominent feature of this strain is its tillering properties. In every respect is this a good variety for general use.

Archer's Stiff Straw.—A very prolific Barley, and, as its name implies, it is not so liable to lodge, owing to the stiffness of its straw. It is an exceedingly good variety for general use.

Goldthorpe.—This Barley was introduced in 1889 by Mr. Dyson, of Goldthorpe, and is highly prized by many.

Standwell.- This sort is said to ripen earlier than any other variety, which is a distinct point in its favour. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham.*

Obituary.

JOHN POPE.—By the death of Mr. John Pope, which occurred on the 26th ult., in his 71st year, a well-known and highly esteemed personality has been lost to Midland horticulture. The deceased's family had been associated with the nursery business for upwards of 130 years. The founder of the firm—Mr. Luke Pope—who was born in 1740 and died in 1825 at the ripe age of 85 years, was the great-grandfather of the late John Pope. The business was established at Gibb Heath, in the Handsworth district of Birmingham, where it was continued until 1865, when, owing to the growth and changed conditions of the neighbourhood, together with the increasing atmospheric impurities, the business was transferred to King's Norton, at that time an open agricultural district in Worcestershire, about five miles from Birmingham. About seven years ago the failing health of Mr. Pope necessitated the closing down of the business, with the exception of the Daffodil portion of it, which is still being carried on by his two daughters. Deceased took an active interest in all matters relating to horticulture. He was mainly responsible for the establishment of the King's Norton Floral Society, and for a time acted as hon. treasurer. His connection with the Birmingham Chrysanthemum Society extended over very many years. He was also a warm supporter of the Birmingham Gardeners' Mutual Improvement Society since its inception in 1886. The part he took in assisting the late Mr. Robert Sydenham to found and carry on the Midland Daffodil Society will be within the recollection of early members; and he also served on the Daffodil Committee of the Royal Horticultural Society. His remains were interred in King's Norton churchyard on the 30th ult.

HENRY CARINGTON BOWLES.—We regret to record the death of Mr. Henry Carington Bowles, J.P., for many years Governor of the New River Company, who has died at Myddelton House, Waltham Cross, at the age of 87. Many of our readers are familiar with the beautiful gardens at Myddelton House, which are the especial care of Mr. Bowles' son, Mr. E. A. Bowles, a very keen horticulturist, the chairman of the R.H.S. Scientific Committee, and a member of the Floral Committee.

Answers to Correspondents.

CAMELLIA: *A. D. H.* The ashes spread over the surface of the border would not in themselves be harmful to the Camellias, but they might conceal the fact that the border was getting too dry, and thus lead to slight neglect as to watering. Further, we do not think the composition of the soil you are using is quite suitable; it should consist mainly of fibrous, turfy loam, such as the top spit of an old pasture, the re-

LUKE POPE, *circa* 1740-1825.

mainder being made up of tough peat and well-decayed leaf-mould from such trees as the Oak and Beech. To this compost some silver sand may be added to keep it porous, but the soil must be made very firm and thoroughly well drained. Charcoal added to the compost will serve to keep it from becoming sour.

NAMES OF FRUITS—*In the naming of fruits, we desire to oblige our correspondents as far as we can, but the task would become too costly and too time-consuming were there no restrictions. Correspondents should observe the rule that* NOT MORE THAN SIX VARIETIES *be sent at any one time. The specimens must be good ones, if two of each variety are sent, identification will be easier. The fruits should be just approaching ripeness, and they should be properly numbered, and carefully packed in strong boxes; cardboard is often smashed in the post. A leaf or shoot of each variety is helpful and in the case of Plums, Peaches and Nectarines, absolutely essential. In all cases it is necessary to know the district from which the fruits are sent. By neglecting these precautions, correspondents add greatly to our labour and run the risk of increased delay and incorrect determination. We do not undertake to send answers through the post, or to return fruits. Fruits and flowering plants must not be sent in the same box. Delay in any case is unavoidable.*

Chelwood. Clay-gate Pearmain.—*T. L. I.* 11, Ashmead's Kernel; 16, Fearn's Pippin; 27, Sturmer Pippin; 5, Gascoyne's Scarlet; 17, Egremont Russet; 1, Royal Russet; 9, decayed; 23, Cox's Orange Pippin; 24, not recognised—probably a local variety.—*G. H.* Reinette Van Mons.—*J. E. A.* Glou Morceau.—*F. B. L.* 1, D'Arcy Spice Pippin; 2, Annie Elizabeth.

POLLINATING PLUMS: *W. W.* Victoria or Czar would be a suitable variety as a polleniser for Kirke's Plum, which can scarcely be termed an early variety. Coe's Golden Drop might serve, though it is one of the least self-fertile Plums. Nearly all the Gage Plums fruit better when pollenised by other sorts, but Denniston's Superb Gage is a self-fertile variety. Probably this Plum would be too nearly off blossom when Kirke's was in full bloom to be a good polleniser for it, but a tree or two might be tried, as the variety is well worth growing. This may also be said of Oullin's Golden Gage.

POTATOS FOR SANDY SOIL: *R. J. E. M.* The variety King Edward VII. is an early main-crop and one of the most productive, but while it is quite suitable for sandy or heavy soils it does not succeed in sheltered gardens of restricted space. The tall haulm even gets destroyed by aphides and the tubers fail to mature, remaining watery and tasteless. Do not, therefore, plant King Edward, Arran Chief, or other tall growers in closely fenced gardens. The variety Sir John Llewelyn is of medium height, and produces large, kidney-shaped tubers of excellent quality in sandy or chalky soils. Other dwarf or moderate growers, of good quality and productive, are Early Puritan, Duke of York, and Sharpe's Express. Somewhat earlier and equally good are Harbinger, Midlothian Early, Witch Hill, and May Queen, the last being one of the earliest. In case the first-named may be sold out, the other six will give you choice of substitutes. May Queen is excellent for early borders and forcing, but may not crop so heavily as the others in sandy soil. All are white-skinned and white-fleshed except Duke of York and Midlothian Early.

RED CURRANTS ATTACKED BY FUNGUS: *C. E.* The dark red excrescences on the shoots of your Red Currant are the ascigrous stage of a fungus known as Nectria cinnaharina, the common name being Coral-spot Disease. The fungus is commonly seen on dead branches, and especially on old Pea sticks. The species also commonly lives as a parasite, and in the case of living plants, gains an entrance through wounds in the bark. The fungus spreads in the interior tissue, and is often present in parts not apparently affected. Cut out all the disfigured branches well below the pustules, and burn them, together with all fallen twigs or branches.

TURF: *J. H.* The unsatisfactory condition of your turf is apparently due to lack of drainage. The sample you sent us is in a very sodden condition, and the weak, unsatisfactory growth of the grass points to insufficient aeration of the soil. First thoroughly drain the land, and then top-dress the sward with some rich compost, such as old potting mould mixed with well-rotted rung. Sweepings from gravel roads, provided they are free from motor oil and petrol, would also be beneficial. If the lawns are not used in winter, dress them in late autumn with farmyard and stable manure, and use a brush-harrow to disintegrate the litter in the spring, afterwards finishing the process with a wooden rake. About the middle of February or beginning of March, give the turf a dressing of some nitrogenous manure, such as sulphate of ammonia, at the rate of one ounce to the square yard, and repeat the application after an interval of a few weeks. Do not employ phosphatic manures, as they tend to encourage the growth of Clover, which is present in the turf you sent. If worms are troublesome, use corrosive sublimate in the proportion of half an ounce dissolved in fifteen gallons of water. When the worms come to the surface they should be swept up, as they would poison fowls which might eat them.

HIPPEASTRUMS.

HIPPEASTRUMS, which in many gardens are still known as Amaryllis, are propagated from seeds and offsets; the flowers are easily cross fertilised, and, as a rule, the plants produce seed freely, so that the usual method of propagation is by seed.

When the seeds are harvested they should be dried for a few days, and then sown in pots or pans filled with light, sandy soil, taking care not to cover them too deeply. The seed pan should be plunged in a propagating case having a bottom heat of 65° to 70°.

When large enough to handle the seedlings should be pricked off into pots of light, rich soil, and later they should be potted singly into small pots. The pots containing the seedlings should be plunged in a mild hot-bed, where, in a temperature of 60° to 70°, enclosed with a moist atmosphere, they should make rapid progress. The plants should be afforded larger pots as they require increased root space but very large pots should not be used; until the plants reach a flowering size receptacles 5 or 6 inches in diameter are quite large enough. If well grown, a goodly proportion of the seedlings should be of flowering size at the end of two years.

After having attained to flowering size and fully completed their growth, the plants should be rested by withholding water and lowering the temperature. Where large quantities are grown, and suitable conditions available, the seedlings, instead of being grown in pots, may be planted out in beds. If this method is adopted the seedlings should be pricked off into pans or boxes and grown on for a time until they are large enough to plant out. The most suitable place to grow the bulbs in this manner is the bed of a propagating house where there is bottom heat.

A layer of clinkers should be placed at the bottom of the bed for drainage, and over the clinkers a layer, some 6 inches deep, of good mellow loam, mixed with a little bone-meal, leaf-mould, and coarse sand. The bulbs may be planted 6 inches apart, and, with attention to syringing and watering, they should make rapid progress.

At the end of two years, when a proportion of the bulbs have attained flowering size, they should be lifted and potted for flowering, but before this is done they require to be rested by a gradual drying off, and if possible a lower temperature.

The resting or drying of the bulbs requires considerable care and judgment, as they must not be subjected to drought when they are growing. Water should be withheld as they are completing a period of growth; this is rather difficult to explain, but it may be most clearly explained by saying that the young seedlings make their growth in periods or cycles, with little or no rest between. If they are kept supplied with water, soil, and atmospheric moisture. This slight natural pause in their growth may be told by observing that there are no young leaves showing in the centre of the plant. The observant cultivator will anticipate this period by gradually withholding water; such a period with young plants should occur about October and November.

When the foliage has nearly all died down the bulbs should be lifted, and potted in suitably sized pots, using receptacles of the smallest sizes that will hold them. Plunge the pots in a mild bed, and the plants should soon start into growth, and a proportion of them show for flowering.

The potting or repotting of the plants is possibly the most critical stage in the culture of Hippeastrums, for unless great care is exercised they usually suffer from over-watering before they have made new roots. If through over-watering growth is weakened the plants fall an easy prey to the bulb mite, which seems always to be present in a collection.

Plants in flower may be removed to a warm greenhouse or conservatory, and when flowering is over they should be returned to the growing house and potted on if necessary. During the summer they may be placed outdoors, but the danger of frost in autumn and winter must be carefully guarded against. Water must be carefully applied, as the bulbs are now in full growth and the pots filled with roots; ample supplies of water are necessary, and dilute liquid manure or soot water should be used twice a week, alternately with a concentrated fertiliser.

As the plants complete their growth, water and liquid manure are withheld, the plants lifted from the beds and placed in a cooler house, where they can be exposed to full sunshine.

When required to flower in the house they may be started into growth in January, February, or March, according to the season they are required to flower. Those that do not require repotting should be selected for the earliest flowering batches, for, being established in the pots, they readily start into flower and growth.

Regarding the general collection, as the plants complete their growth they should be taken from the bed and removed to a cooler and drier house, and water gradually withheld. Early in the New Year they should be examined, and all plants requiring repotting should be shaken out, cleaned of all loose scales, the decayed base of the bulb and decayed roots, washed with an insecticide, and afterwards dusted with lime, powdered charcoal, and flowers of sulphur. Afterwards repot them in clean, carefully drained pots, using receptacles of a small size. The compost should consist of good medium loam with the addition of a little bone-meal, soot, leaf-mould and sand.

Plants in good condition at the root should have some of the surface soil removed, replacing it with a top-dressing of a rich compost.

PROPAGATION BY OFFSETS.

Propagation by means of offsets is adopted when it is desired to increase the number of any particular variety. The offsets should be detached when the plants are being repotted, taking care not to damage the base of the bulb. The offsets are the more readily detached without injury if left until they have grown to a considerable size. They should be potted up in small pots and treated in every respect like the older bulbs.

Unless it is desired to increase any particular sort by this means, offsets are best cut away from all flowering bulbs.

Red spider attacks plants grown in a dry atmosphere, but can be kept in check by syringing with clear water. Thrips are often troublesome, and may be kept in check by the same means and by fumigating. Mealy bug and bulb mites are the worst enemies. If mealy bug gains a footing on the plant it is very difficult to eradicate, as the pest gets between the scales of the bulbs, where it is difficult to dislodge. The only remedy is sponging and brushing them out with an insecticide. Hippeastrums should not be grown in houses containing other plants.

The bulb mite (Tyroglyphus longior) is said to be accompanied by a fungus (Sporotrichum Sarcoptidarum), which appears as white patches on the mites. Some gardeners say it is caused by the presence of the mite, others hold that it precedes an attack. I myself believe that mite is always present in a collection, and is more or less harmless, until some error in cultivation, such as over-watering, weakens the plants and lays them open to attack.

If a collection becomes badly infested, prompt and drastic measures are necessary; the bulbs should be shaken out, all loose scales and decaying parts removed, and the plant washed carefully in an insecticide. Place the bulbs head downwards to drain, and afterwards dust them with powdered charcoal, lime, and flowers of sulphur. They should be potted in fresh compost.

The house should be cleared out and thoroughly cleansed, removing and destroying all plunging material. The walls of the plunging-bed should be well scrubbed with hot water and soft soap, and afterwards sprayed with a strong solution of carbolic acid.

All wall surfaces should then be washed with fresh lime, to which is added a good handful of flowers of sulphur to every bucketful of limewash. *J. C.*

PLANT NOTES.

HIPPEASTRUM ACKERMANNII OR ACRAMANNII.

THERE seems to be a difference of opinion with regard to the correct name of this old hybrid Hippeastrum or Amaryllis, as it is still frequently termed. In Nicholson's *Dictionary of Gardening*, and in the two *Kew Hand Lists of Tender Monocotyledons* of 1907 and 1915, it is spelt Ackermannii. This would appear to be conclusive evidence of its correctness, but in an article on Hippeastrums in *Hortus Veitchii*, p. 467, the name is referred to as Acramannii, with the following explanation: "This received the name of Acramannii (and also the erroneous one of Ackermannii), and was the result of a cross by Messrs. Garraway and Sons, of Bristol, in 1835, between Hippeastrum aulicum, H. platypetalum, and H. psittacinum. It was named Acramannii in compliment to G. Acraman, Esq., of the city of Bristol. This was unquestionably the finest hybrid yet raised, but a few years later was eclipsed by a seedling of the same firm, flowered in 1850 from Hippeastrum aulicum crossed with the hybrid Johnsonii, named Acramannii pulcherrima, from a resemblance it bore to the original hybrid. This last is of great interest, as one of the parents used by Messrs. Veitch some years later, in the production of the first Hippeastrum raised at Chelsea." *W. T.*

AGAPANTHUS UMBELLATUS IN THE OPEN.

IT may interest readers who cultivate the Agapanthus as a hardy plant to learn that Agapanthus umbellatus, in a dry border facing

south-west, and sheltered from the north-west, north, and east, remained quite fresh and green until the fourth week of December, when the foliage was touched by frost, became flaccid, and lost some of its colour. The plant is unprotected in winter, save by its own foliage, which I find sufficient to save it in the spring, when the young leaves are most liable to injury. A plant of A. Mooreanus, with the same exposure, but not so sheltered, lost its freshness early in November, and the old leaves are now soft and colourless, although it is in other respects hardier than A. imbecillanus. — *S. Arnott, Sunnymead, Maxwelltown, Kirkcudbrightshire.*

COLUMNEA BANKSII.

AMONG the more valuable stove plants that have been introduced to our gardens during recent years are several handsome species of Columnea, including the erect-growing C. magnifica, C. Oerstediana, and C. Zahnii, all of which have large scarlet flowers, the last two being of pendant habit. For long before these species were introduced we had the pretty C. scandens and the sombre-coloured but curious and attractive C. Schiedeana, and now to these have been added certain hybrids raised at Kew and Cambridge, so that it would be easy to make up a charming group of these useful basket Gesnerads. One of these hybrids is illustrated in fig. 27. It was raised by Mr. G. H. Banks, now of the Botanic Garden, Glasgow, when foreman of the Cambridge plant houses, and I have pleasure in giving it his name. It was raised between C. Schiedeana, the mother parent, and C. Oerstediana, perhaps the finest of the three species first mentioned above, and is an improvement on either parents, inasmuch that it is equally as showy as the male parent, C. Oerstediana, and much more robust in growth. While C. Oerstediana unfortunately has been lost here, C. Banksii lives on quite happily. The hybrid shows clear traces of the C. Schiedeana in certain obscure markings of the flower, but the leaves are much smaller, and in the colour and size of the flower and also the shape of the leaf, it is entirely different. In colour of flower, in habit, and foliage it most nearly resembles C. Oerstediana. The corolla is 3 inches long, and measures about 1½ inch across; the upper lobe measures about ¾ inch in width and the same in length, while the narrow lip is ⅞ inch long, and rather more than ½ inch in breadth. The exterior of the corolla is sparsely hairy, and the corolla is curiously saccate at the base, the pouch probably secreting honey. The mouth of the corolla is marked by obscure yellowish lines from the influence of C. Schiedeana. There is a curious thick scale-like gland at the base of the ovary. A hybrid raised in these gardens and at Kew between C. glabra and C. Schiedeana has also a more robust habit than C. Schiedeana. The cultivation of Columneas is not, as a rule, difficult; C. Oerstediana and C. glabra, however, require careful treatment. These plants, though belonging to a different tribe of the Gesneraceæ, strongly recall the genus Aeschynanthus, but the members of the latter genus are Asiatic plants, while Columneas are all natives of tropical America. *R. Irwin Lynch.*

THE ROSARY.

SPECIALLY USEFUL ROSES.

ONE of the most experienced of English rosarians recently gave it as his opinion that of all the many new Roses annually brought into commerce, not more than two or three survived the third year of their introduction to an interested but critical public, and he believed this to be true alike of those varieties which did or did not receive the distinction of a Gold Medal, Award of Merit, or similar mark of approbation, when exhibited. He added that the proposition would be found to be equally true if applied to the new Roses observed while growing and reported on at the trial grounds at Bagatelle, in Paris. Seeing that the number of new Roses introduced into commerce yearly is 200 to 300, this would give only about 1 per cent. of new Roses that become popular varieties, and the inquiry of a bystander whether raisers were aware of the kind of Roses sought for by the public, was in the circumstances not unnatural.

Raisers take very considerable trouble in testing and selecting seedlings before putting them on the market. Only small numbers of the best seedlings are retained and propagated, and many stories are told of Roses that have proved really satisfactory being saved from the rubbish-heap by some accident; it therefore seems to be the case that any real test of the suitability of a Rose for garden purposes can only be applied by trial in the garden. If this be so, we must not expect to be able to form a final opinion of any new variety until it has passed the only test that is worth consideration and the variety has been in actual cultivation for three or four years.

Let us consider the best dozen Roses for garden purposes, confining ourselves for the moment to the Hybrid Teas, as perhaps the most popular class among the generality of Rose growers.

The first half-dozen will require little consideration, and we may take as easily pre-eminent:—Mrs. E. G. Hill (pink), Caroline Testout (pink), Mrs. Edward Powell (crimson), Mme. Ravary (yellow), Mme. Léon Pain (salmon), Mme. Edouard Herriot (copper).

The next half-dozen will be more difficult of selection, but we shall probably not be far wrong with:—General McArthur (crimson), Gruss an Teplitz (crimson), Ophelia (blush pink), Prince de Bulgarie (apricot), Mme. Abel Chatenay (pink), Papa Gontier (pink).

Judging from my own garden and private preference, Richmond should have had a place, but I am conscious that some do not find it a success, and have therefore omitted it.

What, then, are the qualities that secure these Roses their pre-eminence as garden plants?

1. Possibly one should put first continuity of flowering, or at least a constant succession of flowering periods, with no long flowerless intervals between them. In this particular Richmond is unsurpassed among the H.T.s, but Mrs. E. Powell is nearly as good, and a better grower.

When the revival of gardening took place in the 17th and 18th centuries the Rose held for some time no very high place, and was quite secondary in interest to the Tulip, the Carnation and the Daffodil. This is often put down to the Court influence of Dutch William and the particular interests of the gardening writers of those days, but there was another and better reason for it. The Rose was then only a summer-flowering plant. When, under the influence of the three forms of R. indica, it became perpetual, or at least autumnal, its status rapidly and wholly changed, and with the growth of its perpetual character during the first half of the 19th century it easily outdistanced its competitors as a garden favourite. Continuity of flowering into late autumn is therefore of capital importance.

2. Closely associated with the last character

is that of copious and healthy foliage. The antithesis of the flower and the leaf is a poetical conception, "and which will ye honoure, Tet me I pray, this yere, the Leafe or the Floure," and the poet chose the leaf. Perhaps he was right, for the wrong reason, as may sometimes happen with great men; for it is very certain that without the leaf there will be no flower. One has only to notice the dire destruction of all autumn flowering that may result in a garden from an attack of black spot, that strips the leaves from the plant and ends its flowering for the year; this will convince the most sceptical how closely healthy foliage is connected with beautiful blossoms.

In this connection there are some Roses on my list to which exception might be taken, for Mme. Abel Chatenay and Papa Gontier are somewhat sparse in foliage, and Gruss an Teplitz and Prince de Bulgarie, though when healthy they have copious and particularly beautiful foliage, are both rather readily attacked by black spot disease. To those who find the dwarf Papa Gontier too poor in growth I would recommend the climbing variety.

3. Hardiness is, of course, a necessity, and without it a variety rapidly disappears, but in this respect there is little to complain of as a rule among new Roses.

4. Colour is certainly important, in the sense that it should be definite. It is certainly the case that in the past we have been offered too many varieties of rather washy colouring. In this respect the late autumn flowers of Mme. Ravary leave much to be desired, but a good yellow variety that will retain its colour through the late autumn is still wanting; the second flowering of General McArthur is often poor in colour if hot sunshine prevails.

5. Form in the flower is the character that is most wanting in my list. Mrs. E. G. Hill, Ophelia, and Mme. Abel Chatenay have flowers that are nearly always well formed, while Caroline Testout, Mme. Ravary, Mme. Léon Pain, and Prince de Bulgarie are usually fairly well shaped, but most of the others are capable of a good deal of improvement in form, particularly in the centre of the flower, which often has relatively short petals.

6. Rain resistance, or the power to open the flowers well and retain them when open for a certain period of time in tolerable condition during wet and stormy weather is, in this country, of the utmost importance for a garden Rose. To accomplish this, the petals ought not to be too densely packed in the flower, lest the outer ones perish while still wrapped tightly round the blossom, which rots before it can open. Again, the petals must themselves be stout and leathery in texture to be able to resist rain as well as disease. For its size, Mrs. E. G. Hill is particularly good in this respect; and after two days' rain the beds of these plants will be found full of fine flowers. Mme. Léon Pain is rather easily spoilt by rain, but produces a fresh set of flowers so quickly that the spoiled blooms are hardly noticed.

7. The power to produce a fair proportion of good flowers without disbudding is another useful quality. The variety Mrs. E. G. Hill will do this, as will many of the H.T.s, both early and late, but in the late summer or second flowering they are apt to push up a single strong shoot bearing very numerous flowers, which are of little use if not thinned, while others somewhat resemble the H.P.s, and normally carry a group of flowers at the apex of the shoots. There would be much to be said in favour of a Rose that would habitually bear a number of branches, each carrying a single flower at the apex.

8. Finally, the good garden Rose must be a vigorous grower, producing stems stout enough to carry the flower erect, or nearly so, and yet not grow so wildly as to be unruly and unsuited for the restraint necessary in garden beds and borders. In this respect few varieties excel Mme. Ravary, which habitually makes numerous short-jointed branches, which ripen quickly and well. This good habit of growth, as it is called, is alike an absolute requisite and the point where new Roses most often fail.

It is to qualities such as these that we must devote our attention in experimenting with and selecting new Roses. The complaint that too many new Roses are offered—that we are overdone with varieties—is a very old one, and is alike unwise and unfair, as I hope to show; it was voiced by Rivers in the fifties and Shirley Hibberd in the sixties, and we hear it to-day. Now, if we begin to try to improve annuals, as Mr. Wilks did his Shirley Poppies, we may sow the seed and begin to select and breed from the best plants in the course of a season. It is not so with Roses, as it is often some years before seedling Roses flower. Finally, a stock of the selected seedlings must be budded, and a preliminary observation affirmed or rejected. The best are brought into commerce, and the public is able to purchase them and commence observations for the purpose of approval or rejection in the ensuing season.

The late Sir Michael Foster once remarked that the most interesting part of gardening was the raising of seedlings and the watch for improvements on existing types. The raisers have done the preliminary work of hybridising and the rejection of the obviously worthless, and it remains for the gardener to enjoy the process of subjecting the results obtained to the final test of cultivation in the garden. In this spirit he will secure much interest and satisfaction from the study of new varieties.—*White Rose.*

TREES AND SHRUBS.

THE RED OAK.

At least three species of the Oaks of eastern North America bear the name, or merit the name, of Red Oak, by reason of their richly coloured autumn foliage. But Quercus coccinea (*i.e.* perhaps, the strongest claim to this distinction. My attention was attracted in late autumn to a lovely avenue of trees of this species growing on a small estate here in Henfield, Sussex, called "Red Oaks" held by the Rev. H. B. Dunlop. When we arrived at Henfield at the beginning of October, Scarlet Runner Beans and Dahlias were still flourishing, but by the middle of the month these exotics were in rags. Soon the trees assumed their varied autumn tints, which were very brilliant in this district of noble trees. The gold of the Elms and the crimson of Quercus coccinea were perhaps the finest and certainly the latest of the colour tinting, the foliage surviving ill of frost in mid December. We had sunny days at the time, which brought out the most striking colour effects.

The Red Oaks house, Mr. Dunlop informed me, was built in 1536, and the original Oaks were planted about the same date. There are several trees, all more or less damaged by the terrific windstorms that occasionally sweep over the Downs. The best specimen is about 60 feet high, with a spread of 76 feet and a girth of 6 feet 3 inches. Examples, of similar dimensions, exist in West Dean Park, Chichester. But this Red Oak is still very rare in the United Kingdom, though it must have been introduced very early, as a specimen is said to have been growing in Bishop Compton's garden at Fulham in 1691. At Henfield, as I was told by Mr. Park, the gardener, Quercus coccinea rarely bears Acorns, and never more than a very few—so few that they are germinated in pots to escape being eaten by mice. Some young trees, about ten years old, retained their brilliant foliage longer than any other kind of tree. The leaves, it may be added, are elegant in shape and delicate in texture, with brittle-tipped ultimate lobes and borne on long, slender stalks.—*W. Botting Hemsley.*

NOTES FROM AMERICA.

THE JERUSALEM ARTICHOKE.

The so-called Jerusalem Artichoke is really a Sunflower, Helianthus tuberosus, and a native of the United States. It is one of a group of tuber bearing Sunflowers, and was known to the Indians as an important source of food before the arrival of the white man. According to Dr. V. Havard, the tubers were mentioned by Champlain as early as 1605, and were brought to France by Lescarbot, who, in 1612, described them as being "as big as small Turnips, excellent to eat, with the taste of Artichoke, but more agreeable, and multiplying in a wonderful way." Parkinson, in 1629, said that the tubers were commonly offered for sale in London. In spite of this excellent start, the plant has of late years been little used in America, except more or less as food for hogs, which do their own harvesting. Vilmorin has long advocated its use in France, offering four varieties in his catalogue. Sutton's catalogue (1917), just received, lists three varieties, with a statement that six pounds of tubers planted gave a yield of 16 stones. Here, in Boulder, Colorado, we raised them this year in unfertilised ground at the rate of 9.66 tons to the acre. They were planted 3 feet apart in the row, which were made 2 feet apart. Apparently they could be more crowded without disadvantage. There were no pests of any consequence. We have used the tubers a great deal as a vegetable, and like them very much. According to published analyses, they have about the same food value as Potatos, with a little more protein (2.6, as against 2.1 per cent.) and less carbohydrate. In other places very much larger crops have been recorded. Thus in the State of Washington it was reported by W. H. Lawrence that, in 1909, Red Jerusalem Artichokes yielded at the rate of 20.26 tons to the acre, and in 1910 the White variety, on sandy soil, cropped at the rate of 38.9 tons per acre. When fertiliser is used, H. Blin concludes that potash is the important element to be supplied.

In view of all these facts, it seems that this plant should be more freely grown, especially in war times, when it is so important to get a maximum yield.—*T. D. A. Cockerell, Boulder, Colorado.*

THE EFFECT OF ONE PLANT ON ANOTHER.

Mr. Spencer Pickering's crucial test (see Oct. 27, 1917, p. 170) in growing three Mustard plants in separate pots and submitting one of them to seepage from a tray containing soil in which Mustard had been sown or was growing, proves that plants of the same species develop an aversion from growing in the company of each other. This aversion, or toxic principle, is well known and pronounced with Cruciferous plants. Mr. Pickering repeats his experiment as related in the third column of p. 170. The whole tenor of the experiments, and the assertion that the roots of grass form a poison detrimental to tree growth, has not been proven; at least, the evidence as submitted in the columns of the *Gardeners' Chronicle* is inconclusive. There has been much controversy on the question of growing grass in orchards, for a half century or more. Thomas Meehan, while editor of the *Gardeners' Monthly* contended that he could never see that evil results followed. Growing grass in orchards, especially in the case of old trees, in my experience seems to serve as a check on the over production of wood, and acts in the very same manner that root-pruning does in developing fruit-spurs. It is virtually a check. Young Apple orchards, on the contrary, are benefited by being kept clean and the soil cultivated, but it is a common practice toward the end of the summer to sow the ground down to winter Wheat or Rye. Grass in orchards removes from the soil great quantities of moisture, and in a

sense robs the trees of nourishment yet it may have the effect of causing the young growths of the trees to ripen. The evil, if any—which I very much doubt in the case of old trees—is physical, and not toxic. *Mr. c. MacElwee, Philadelphia.*

SUNFLOWER SEED OIL.

ACCORDING to a report* to the National Paint, Oil and Varnish Association (U.S.A.), oil from Sunflower seeds may be used instead of Linseed oil in mixing paint. Almost as good as the latter so far as paint is concerned, Sunflower oil is said to be superior to Linseed oil for varnish.

STANGERIA PARADOXA.

STANGERIA might be called a freak genus of an order, Cycadaceæ, which occupies an isolated position in the vegetable kingdom. The plant has a stem that suggests a Turnip, and leaves which in form and venation so closely resemble some Ferns that when first introduced it was mistaken for one, and was actually described as a Lomaria. The inflorescence is a cone, in the male plant cylindrical (see fig. 28), and in the female plant short, after the style of an Artichoke (see fig. 29). The plant grows wild in South Africa, the largest forms of it being found in the tropics, whilst in the more temperate regions it is quite stubby. A botanist might find material in the variations for half-a-dozen species, or, if reasonable, look upon them all as forms of one. The plant has been in cultivation since 1851 when it was sent to Mr T. Moore, Chelsea Botanic Gardens, as a Fern. The largest specimen I have ever seen is at Kew, and it came from Hermann Wendland, who grew it in the botanic gardens at Herrenhausen. The cones illustrated were produced at Kew, the three males by the big plant which for many years has been cultivated in the Victoria House, the conditions there being evidently to its liking. *W. Watson.*

FRUIT REGISTER.

UNDESIRABLE APPLES.

THE published lists of Apples, which include something like 300 varieties, could be much reduced with material gain to the community. There are some who advocate the planting of numerous sorts on the ground that if one fails to crop others may not. If the latter are varieties of poor quality there is not much gain. Nurserymen are not in favour of so many varieties: too often to them it means occupying valuable space for some years with sorts that can only satisfy the whim of a few customers, when trees of three sorts will prove much more satisfactory. Gardeners in large establishments plant many varieties, knowing that their employers like to see a well-filled fruit room with much variety. I need hardly say that not to this class of cultivator, but rather I try to teach those with little experience which are the most desirable sorts to grow. The following varieties could easily be dispensed with to a start, as there are others more valuable in season at the same time:—Emmaus's Benette, Middlecott's Pearmain, Nancy, Yorkshire Beauty, Wealthy, Monks' Codlin, Betty de Potton, Beauty of Stoke, Barchard's Seedling, Bess Pool, No Surrender, Lemon Pippin, Cockpit, Bedfordshire Foundling, Crimson Queening, Dr. Harvey, Duchess's Favourite, Domino, Glory Mundi, Hawthornden, Gravenstein, King of the Pippins, Royal Oak, British Queen, Wormsley Pippin, Red Astrachan, Ashmead's Kernel, Allfristo, Scotch Bridget, Rougemont, Castle Major, Scarlet Nonpareil, Queen Caroline, Schoolmaster, Scarlet Pearmain, Syke House Russet, Yellow Ingestre, Barnack Beauty, Baron Wolseley, Calville Blanche, Calville Malingre, and Cardinal. *H. Molyneux.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENCER CLAY, M.P., Ford Manor, Lingfield, Surrey

EARLY PEAS.—Rough pits answer well for forwarding dwarf early Peas, with or without glass coverings; large frames can be similarly utilised. The best results usually attend the practice of raising the plants in small pots, turves, or shallow boxes for planting out either in pits or in the open ground. Sow the seeds thinly and germinate them in a cool house. Make a shallow hot bed in a pit, and cover it with a layer of fairly good soil to a depth of not less than 9 inches. By the time the Peas are fit to transplant the soil will be warmed through.

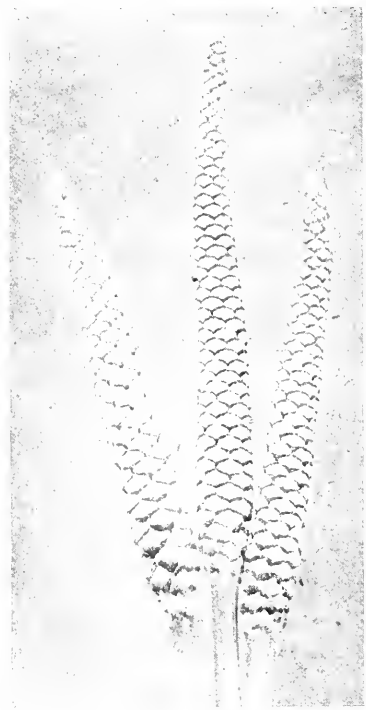

FIG. 27.—MALE CONES OF STANGERIA PARADOXA.

As an early crop is most needed, such varieties as Little Marvel, Eight Weeks, Laxtonian, and Pioneer should be selected; the three former may be put out rather thickly in rows 15 inches apart, but for the stronger varieties allow a space of 18 inches.

PEAS ON EARLY BORDERS. There is always a risk attending very early sowing of Peas out-of-doors, and especially on heavy soils. The Marrow fat varieties being more tender than round-seeded sorts, the surest way is to sow as advised above, and better plants result than when raised in heat. If the soil on a warm border is in a suitable condition such varieties as Pilot and Excelsior may be sown; these would closely follow those raised in frames, and furnish a supply until the taller varieties are ready for use.

SPINACH.—The weather has not been favourable to the growth of Winter Spinach, and the first opportunity should be taken to sow a few rows on a warm border. Scatter the seeds rather freely in shallow drills; later sowings may be made midway between rows of Peas, and repeated as successional sowings of Peas are made to keep up a constant supply. The round-seeded or summer Spinach is the most suitable kind for early cropping.

PARSNIPS.—This valuable winter vegetable is of easy cultivation, provided it is grown in deeply-dug ground free from fresh manure. Parsnips may follow a Celery crop, as the soil for Celery is worked to a good depth. If exhibition roots are required, make holes 3 feet deep and 15 inches apart with an iron bar, filling them with a light, rich compost, and sowing three seeds on the top of each station. The Parsnip requires a long season of growth, therefore the seed should be sown as soon as the weather is favourable and the soil in a suitable condition to receive them. Sow the seeds thinly in drills made 15 inches apart, and thin the seedlings to 6 or 9 inches apart. The Student is a reliable variety, and gives roots of good quality.

RHUBARB.—The growth of Rhubarb may be hastened considerably by placing pots over some of the crowns, as soon as they show signs of starting into growth, covering the pots with long strawy litter and leaves. The present is a suitable time to make fresh plantations of Rhubarb, using stools that have been forced in deeply-cultivated, heavily-manured ground, as the roots grow deeply. Allow a space of 4 feet between the rows and 3 feet between the roots of moderate-sized varieties, but for strong-growing sorts the distance should be 4 feet between the roots in the rows.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

FIG TREES ON WALLS.—It is time to remove some of the protective material, whether evergreen boughs, Bracken Fern, or straw, from Figs trained to walls. In a few weeks it can be taken away entirely, and the nailing and training of the trees attended to. If the trees are growing strongly, and not very fruitful, root-pruning may be necessary. I am of the opinion that if root-pruning were done more generally in the case of Fig trees in the open, there would be greater crops of this fruit. In the case of very luxuriantly growing trees, do not hesitate to prune the roots severely. To sever strong, downward-growing tap-roots it is necessary to open a wide trench at, say, some 3 feet from the wall in the case of medium-sized trees, and 4 feet for large trees. Excavate the soil to a depth of about 4 feet, and work under the ball to search out the gross-growing roots right up to the wall itself. In cases of extreme root growth, if the soil be too much on the wet side, the bottom of the border may need to be concreted. Place on the concrete a layer some 6 inches thick of old broken brickbats, with the mortar still adhering to them. Provide a drain to carry off superfluous moisture, and take means to prevent the Fig roots from passing beyond this drain into soil that will only be productive of leaf growth. Some are over-cautious in disturbing the roots of Fig trees, but I am convinced that it may be advantageously done in many instances. Figs in pots, as an example, may be shaken free of the soil and repotted in fresh compost without giving the tree only the slightest check. In no case is a large border advisable, for the Fig fruits best when the roots are in a restricted area.

SITES SUITABLE FOR FIG TREES.—In fruit gardens enclosed by large walls it is not a difficult matter to find a suitable place for Figs. The trees require the maximum amount of warmth and sunshine, and shelter from cold winds. The roots need a strong calcareous loam, with a free admixture of rough material, such as broken mortar rubble or limestone. In making new borders keep the surface somewhat higher than the surrounding soil to allow excess of moisture to pass readily away. For outdoor cultivation no variety equals the Brown Turkey, either in productiveness or in flavour: it is also as hardy as any; in fact, Figs are much hardier than is generally believed. A glass coping to the wall is a distinct advantage. Trees that have been trained for about two years in pots are the best to plant out-of-doors; they will not be too vigorous in growth.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

PLEIONE.—Plants of P. maculata, P. Wallichiana, P. praecox and P. lagenaria will, as they pass out of flower, soon develop new roots from the base of the young shoots, and at that stage they require repotting. After removing the plants from their pots, the greater portion of the old soil should be removed from the roots, and the pseudo-bulbs separated. In repotting, place several of the plants together in number according to the size of the receptacle, allowing a space of about 1 inch between each pseudo-bulb, taking care not to injure the young roots. Grow the plants in a position near the roof-glass in a house having an intermediate temperature. Afford the roots water sparingly until they have grown well into the new compost, after which give them copious supplies of moisture until the new pseudo-bulbs are fully matured. Syringe the plants overhead on bright days in order to keep down attacks of red spider. A suitable compost may be made with good fibrous loam and peat in equal parts, with sufficient crushed crocks and silver sand added to render the mixture porous.

CYMBIDIUM.—Plants of Cymbidium Traceyanum are passing out of bloom, and those that require to be repotted should be dealt with at once. This species, like many other Cymbidiums, resents root disturbance, therefore, if there is sufficient room in the pot for the plant to complete its new growth it will be better to defer repotting for another season. Moreover, all Cymbidiums flower most freely when the roots are pot-bound. Use a compost consisting of two-thirds rich fibrous loam and one-third peat or Osmunda-fibre, mixed with a liberal quantity of crushed crocks. Place a double row of potsherds over the bottom of the receptacle for drainage. Pot rather firmly, without damaging the roots. C. insigne, C. Lowianum, C. eburneum, and their many hybrids are developing flower-spikes, and require liberal supplies of water at the roots. Soak the compost thoroughly, but allow it to become moderately dry between each application, as nothing is more harmful to Cymbidiums than merely damping the surface when the roots need moisture. All the above-mentioned Cymbidiums grow best in a moist atmosphere, in a house having a night temperature ranging from 52° to 55°, with a rise of 5° or 10° during the day.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

STOCK PLANTS FOR PROPAGATING. Place stools of summer-flowering Chrysanthemums in a warm temperature to induce the rapid production of shoots suitable for cuttings. See that moisture is never unduly withheld at the roots. If the stock of tall Lobelias is insufficient, the stools of these, too, should be placed in warmth, and watched lest pot should destroy them. In any case no long time should elapse before dividing the clumps in pieces and arranging them in cutting boxes in a compost of half loam and half leaf-mould.

PENTSTEMON AND VERBENA VENUSTA.—Pentstemons may be increased if the boxes in which the rooted cuttings are growing are placed in gentle warmth. If the plants are well rooted the use of a little manure will cause rapid growth, and when the tops are sufficiently extended they will strike root quite freely if inserted in sand and kept damp in the propagating pit. Seeds of Pentstemons should be sown forthwith, the seedlings being very slow in making progress, and, if they are small when planted out, the season's display may—or, indeed, almost certainly will—be poor. Another splendid flowering plant for these times is Verbena venusta, a little difficult to manage when not understood, but if the seeds are steeped for 48 hours in warm water, kept warm, sown and barely covered, the seed container placed in a stove temperature and the soil kept quite wet, the seedlings will appear shortly in vast numbers. The seeds continue to germinate for a long time, and the earlier seedlings should be pricked out into other receptacles as they become ready. Another way of propagating is to save the old plants and cut the underground stem into short pieces, which duly form roots and produce shoots.

THE MIXED BORDER.—If the flower border has not yet been forked over, let this be done forthwith. Make a point of doing this work when the stems of the plants are cut over at the end of the season, then all that is necessary at the present time is to break clods with the back of a rake and level the surface smooth, removing all rubbish that may have accumulated during the winter. When this work is deferred until the spring special care is needed that the pushing blades and flower-spikes of bulbous plants are not damaged or destroyed. Roses growing in the border should be pruned before proceeding to fork up the soil, and a week or two hence, when the surface has been sufficiently weathered, it will greatly improve the appearance of the border to rake it smoothly.

CARNATIONS. It is a mistake to delay the planting of Carnations from pots once the ground is in fit condition. I have reduced my stock of these plants very considerably, their propagation at a critical period for labour being difficult, but much labour may be saved in preparing the ground. I have been very successful with even show varieties and Picotees planted in unmanured ground, and those who still cultivate a large number of Carnations may safely treat their plants similarly.

SWEET PEAS. The sowing of Sweet Peas should be no longer delayed. Sow the seed rather thinly in cutting boxes, covering them with boards until they have germinated, as a precaution against mice eating them. When strong enough the plants should be potted singly into 4-inch pots, and after becoming established in the open border and staked should remain until the end of August. No position is better suited for Sweet Peas than in rows alongside roads or paths, for the flowers are effective and easy to gather. Dorothy Eckford, Countess Cadogan, Royal Purple, Dobbie's Cream, Clarkes Exeter, Duplex Spencer, Queen of Norway, Mauve Christine, Nubian, Afterglow, Asta Ohn, Edison Beauty, King White, Rosabelle and Thomas Stevenson afford a good selection of colours.

FRUITS UNDER GLASS.

By W. J. GOSS, Gardener to MRS. DRUMMOND, Keele Hall, Newcastle, Staffordshire.

EARLY FIGS. The earliest fig trees in pots require liberal supplies of water. Maintain a moist atmosphere, as the trees are very subject to attacks of red spider. Pinch the shoots at the fourth leaf, and keep the growths neatly tied to trellises. Liquid manure or other stimulants may be given the roots once or twice weekly when the fruits are swelling, but not if the trees are making excessive growth: The syringe should be continued until the fruits of the second crop are advanced. Established trees need constant attention in pinching and disbudding the shoots. It is necessary to remove all superfluous growths in their early stages, to prevent undue strain on the resources of the trees. A free use of the syringe will do much to keep red spider in check, and in this respect especial care is necessary where the trees are growing on trellises near the roof-glass. The large fig at Keele furnishes the whole roof of a house 51 feet long by 21 feet wide. The border is 4 feet wide, 35 feet long, and 21 feet deep. Seven varieties are grafted on this one old tree, and two heavy crops ripen annually. The tree is syringed with warm water twice daily, except in cold, dull weather, until the fruit commence to ripen, then a drier atmosphere is maintained. Directly the first crop is gathered syringing is again resorted to. A temperature of 60° should be maintained in the early house, with a rise of 10° by sun-heat.

EARLY STRAWBERRIES.—When the earliest Strawberry plants in pots have set their fruits, commence syringing again with tepid water twice daily during fine weather. Feed the roots with either liquid manure or a concentrated fertiliser once or twice weekly until the fruits show colour. These fertilisers should not be used too liberally, as strong doses would cause the fruit to have a bitter taste. Maintain a free circulation of air, and see that the plants do not suffer for want of water.

MELONS.—If the early Melon plants are not very promising it will be better to make a fresh sowing, for weak plants rarely fruit satisfactorily. The weather has been favourable to Melons, and with the lengthening days the plants should grow freely. Prepare the pots or beds a few days in advance of planting, to allow the soil to become warmed through. Place a heap of rich, fatty loam on a hot-bed formed of short manure and leaves. Plant firmly, whether in pots or beds. Plunge the pots into the fermenting materials. Maintain a night temperature of 70°, rising to 85° by sun-heat. Do not water the roots excessively, as this would cause the plants to collapse, and, unless the weather is exceptionally fine, one light syringing early in the afternoon at the time the house is closed will suffice. Place a neat stake to each plant preparatory to training them up the trellis. Make a further sowing to provide plants for successional cropping.

THE VINERY. Where young Vines were planted in a restricted area of an inside border last year, the cutting walls of turf will be found to be a mass of fibrous roots. Presuming the border was made 4 feet wide at the time of planting, a further similar area may now be added. The bulk of the material for forming the border should consist of firm, fibrous loam, mixed with rough mortar or lime rubble, crushed bones and charcoal or wood ash.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

DRACAENA. Old plants of Dracænas which are becoming bare of leaves at the bases or are otherwise unsatisfactory may be made use of for propagating young stock. Specimens with good heads should be stripped of their lower leaves and the stems notched an inch or two below the remaining foliage. Over the notched portion of stem place a little turfy loam and fine sand. Cover this with a handful of moss and tie the whole tightly together with raffia. Place the plants in a house having a warm, moist atmosphere, and syringe them frequently with lukewarm rain water. Never permit the moss to become dry. In a few weeks the stems above the notch should be sufficiently rooted to be severed and placed in a suitable-sized pot. Afterwards grow the plants in a close atmosphere and shade them until the roots have become established in the soil. Water the roots with extra care until they have filled the pots. Another method of propagating Dracænas is to cut the stems of old plants into small pieces and bury the portions in boxes of fine sand. Place the boxes in a warm house and keep the sand moist.

ROSES IN POTS. Pot Roses which were placed indoors in the New Year are in active growth and flower-buds are forming. If the plants are well rooted, water may be given more liberally than hitherto. The use of stimulants will give vigour to the flowers, and diluted soot water, supplemented occasionally by a concentrated fertiliser, may be used. The Rose maggot will be active now, and must be watched for and destroyed. Climbing Roses are growing freely, and, if desirable, they may be hastened into flower by closing the house for a few hours in the afternoons, but the top ventilators should be opened in the evenings, more or less, according to the weather. Keep the roots well supplied with water, and if not already done, topdress the roots with well decayed horse manure. Use discretion in ventilating the houses, for if too much air is admitted in unfavourable weather mildew will attack the plants.

HYBRID COLEUS. A batch of Coleus plants may be raised from seed sown now in pans filled with sandy soil. Sow the seed rather thinly, to allow the young plants plenty of room to develop before they need potting. Water the soil copiously, using a very fine rose can. Place a sheet of glass over the seed pans and germinate the seeds in a warm, moist atmosphere. Cuttings may be inserted around the edge of a 4-inch pot. Place them in the propagating case and shade them from bright sunshine until roots form.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41 Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 18—
British Wholesale Florists' Federation, Special General Meeting, Essex Hall, Essex Street, Strand, W.C., 2.30 p.m.

THURSDAY, FEBRUARY 21—
Manchester and North of England Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.6.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, February 14, 10 a.m.; Bar. 30.7; temp, 46.5°; Weather—Dull.

Some Problems arising out of the Food Situation.

The chief problem which every owner and cultivator of a garden has to consider is the means whereby the garden may be best employed in order that it may make the household which it supplies as self-supporting as possible; or, if the garden be a large one, how large a surplus for the general use it can be made to produce.

The problem is not one which is easily discussed in general terms, for the discussion must turn on the size of the garden in relation to the numbers to be supplied from it.

Even though the garden is just large enough to supply the household in ordinary times, it cannot, unless a special effort is made, suffice under present and prospective conditions, for it must, if possible, be made to produce more nitrogenous foodstuffs than were needed when meat was plentiful and cheap, and it should somehow be made to contribute towards eking out the limited amount of fat available for food purposes. Inasmuch as leguminous plants, Peas and Beans, are the chief vegetable producers of nitrogenous foodstuffs, it would appear desirable that a larger area of the garden should be devoted to them. But at the same time it has to be remembered that though Peas and Beans are remarkably rich in proteins (nitrogenous foodstuffs), the yield per acre is far lower than that of crops such as Potatos, which are weight for weight far poorer in nitrogenous food substances. Thus the amount of protein contained in the air-dry seeds of Haricot Beans is about 23 per cent., whereas the Potato in its natural state contains rather less than 2 per cent.

Allowing that good garden cultivation will produce one ton of Beans (seed) to the acre, and that 12 tons of Potatos—no large yield for a garden—are produced on a corresponding area, it follows that the Potato, owing to its richness in carbohydrates (starch), produces more actual food than does the Haricot. There is, however, another aspect of the problem which must be borne in mind, and that is that whereas it would be extremely difficult to live on Potatos alone, or on Potatos and fresh green vegetables, it would be fairly easy to live on a diet of Potatos, Haricot Beans, and fresh vegetables. To obtain enough calories—.3300 per day—to supply the energy needed for active life, 11 pounds of Potatos must be eaten per day—a task which would be beyond the stoutest stomach; but if Beans are added to the diet in fair quantity, and the Potatos reduced correspondingly, a diet sufficient for flesh-forming as well as for energy-producing purposes would be obtained. Fresh vegetables would supply the essential accessory food-bodies (vitamines), and the only food substance likely to be deficient in such a diet would be fat. Yet, as Darwin observed in reference to men in South America accustomed to hard manual labour, their diet consisted solely of Beans and bread.

If, however, the garden is to supplement the butcher's shop as a source of nitrogenous food, and to that end Peas and Beans are grown more extensively, it seems evident that the pleasant luxury of such things as green Peas must be forgone, for in their fresh and unripened state Peas are by no means rich in nitrogenous foodstuffs. It is, therefore, to be concluded that of such crops as Peas, Broad Beans, Runner Beans, and Haricot Beans a certain and considerable proportion should be harvested in a dry state. Unfortunately, not all Peas are equally palatable when eaten dry. Harrison's Glory is said to be a good one. Little Marvel certainly is. If soaked for 24, or better 48, hours and cooked with a little bicarbonate of soda, the latter Pea, within our own experience, makes a good dish. The advantages of soaking previously to cooking are twofold. First, the Peas are softened, and therefore more digestible. Second, and more important, is the fact that when soaked for 48 hours (with an occasional change of water to prevent the growth of moulds and bacteria) the Peas re-develop the health-maintaining vitamines, which disappear during the process of ripening, and hence the well-soaked Peas are more nutritious than are those which are cooked after only a brief immersion in water.

We conclude, therefore, that gardeners with ample space should grow as many Potatos—and especially Second Earlies—and also as many Peas, Haricot Beans, and other leguminous crops as possible. At all events, the present writer is so convinced of the propriety of this course that he is turning his herbaceous borders into "vegetable meat"-producing borders, and intends to plant leguminous food plants in place of the flowers. Add to these measures a couple or more pigs, and the garden should produce enough to supply the household, and hence help to take the strain off the trade supplies.

In the case of the small garden it is not so clear whether the programme just sketched holds, and indeed it is probable that the main space should be devoted to second early and main crop Potatos, Onions (from autumn sowing or transplanted seedlings raised under glass), and the usual green crops, not forgetting the big yielding Parsnip and the accommodating Jerusalem Artichoke.

The big garden could do no better work than devote all the space to be spared to increasing the breadth under Onions. Imported Onions will be scarce, and gardeners with suitable ground can help to supply the shortage.

Reverting to the small garden: the pig, as fat producer, may be impossible; although in this connection it is to be remembered that competent persons claim that household and garden waste combined will suffice to feed the animal. But although impossible in one garden it should be easy for several neighbouring gardens to co-operate in pig-keeping on a small scale—provided that there is someone who understands pig management.

In default of some arrangement of this kind, rabbits and poultry should be tried. The difficulty of obtaining grain for poultry is said not to be an absolute bar to success in poultry-keeping — though here we speak without personal experience, and only on information received. In any case, part of the difficulty can be got over if the open parts of shrubberies and waste garden ground generally—that is, ground not to be used for food crops—is planted with suitable varieties of Sunflowers, the seeds of which when well ripened would be available for poultry.

A point on which some readers may be able to give information is the use of Linseed as food (for human beings or poultry). We are informed that seed of Linseed soaked in water and swollen to a jelly-like consistency forms an excellent basis for soup. If so, its richness in fat might make Linseed worth growing. Lastly, it cannot be urged too strongly that all ground cropped with early food plants should be successionally cropped with garden Beet (for its sugar), and also with Turnips and Carrots, as well, of course, as with the usual Brassicas. Nor should the imperative need of exercising economy in the use of seeds be forgotten. Gardeners can in particular help other small cultivators in this respect by raising seedlings of transplantable plants for distribution in their neighbourhood.

We would welcome on behalf of our readers further suggestions from persons of experience on means to make the gardens of England in the coming year most useful to the country as well as to the owners.

SUGAR FOR JAM-MAKING.—The Royal Horticultural Society has addressed a communication to Sir CHARLES BATHURST, Parliamentary Secretary to the Board of Agriculture, drawing attention to the waste of fruit which will result if, as expected, no extra sugar for the purpose of jam-making is allowed this year to growers of fruit. The Society points out that the refusal of sugar to private fruit growers appears to be based on the argument that to grant it to country growers is unfair to town populations: but the prime requisite is to save the whole fruit crop throughout the country. The suggestion to collect all the small growers' produce and convey it to factories appears to the Council to be impracticable; different dates would have to be fixed for the collection of the different fruits. The sugar grant of last year provided tens of thousands of households with excellent jam, which has been used as actual food, and has released a large quantity of other food stuffs, notably butter and margarine. Finally, the Council points out that anyone possessing a good fruit and vegetable garden can, if he is enabled to make the best use of it, so far reduce his demands upon the public food supply that it is only necessary to encroach upon it so far as meat, bread, and salt are concerned.

DRIED POTATOS IN FRANCE. The French Ministry of Agriculture has issued a leaflet recommending the drying of Potatos for use when fresh Potatos are not obtainable. There are various ways of drying Potatos, but the simplest method, which has been employed for many years by farmers' wives in the Ardennes, is to plunge them in boiling water, peel them, and dry them in the oven. Before use, the only preparation necessary is several hours' soaking in cold water. Besides being useful for human food, dried Potatos can be fed to poultry and other farm animals, thus saving grain stuffs.

A PAPER WEED-KILLER.—An interesting method* of killing weeds in Sugar-Cane fields in Hawaii consists in spreading over the fields, after the dormant canes have been manured, strips of tarred or asphalted felt paper weighing 9 lbs. to the 100 square feet. The protected shoots of the young canes grow through the paper, which is weighted with stones, and the softer-tipped weeds, failing to penetrate it, are smothered. A similar practice has been employed in this country in making lawns. The seed is sown on a treated perishable fabric.

THE GENUS EUCALYPTUS. The thirty-second part of Mr. MAIDEN'S Revision of the genus Eucalyptus treats of seven (Nos. 161-167 closely allied species inhabiting New South Wales and Queensland. E. Blakelyi is here described for the first time, and E. dealbata, of ALLAN CUNNINGHAM, is figured partly from type specimens in the Kew Herbarium. None of the species is of special interest to the horticulturist. E. Seeana is described as a graceful and useful species, ranging from Port Macquarie to Moreton Bay. E. exserta is one of the richest in oil. E. Howittiana was named, by F. MUELLER, after A. W. HOWITT, "the most distinguished citizen Gippsland, Victoria, has produced, who possessed a marvellous first-hand knowledge of various branches of Natural History." His *Eucalypts of Gippsland* is an admirable piece of work. The species in question, which is apparently rare, reaches a height of about 100 feet, with a butt 12 feet in girth.

AUSTRALIAN ACACIAS.—The Acacias of tropical Western Australia form the subject of a most interesting paper by Mr. J. H. MAIDEN, F.R.S., read before the Royal Society of New South Wales on June 6, 1917. A condensed bibliographical summary precedes the systematic section, beginning with WILLIAM DAMPIER, who visited Cygnet Bay in 1688. In 1699 he explored the same coast, as captain of H.M.S. Roebuck, and brought away dried fragments of about a dozen different species of plants, which are now in the Oxford University Herbarium, but there is no Acacia among them. DAMPIER'S small collection was the first sample of the Australian flora brought to Europe. The first specimen, apparently, of a North-west Acacia (A. bivenosa) was brought to Europe by BAUDIN'S expedition in 1804, some 25 years after the first settlements on the East coast. MAIDEN enumerates and discusses 55 species from the "Nor'-west" of Western Australia, but this, it should be explained, does not include the Northern Territory, from which 45 other species are listed. A. delibrata, a very obscure species, has been rediscovered, fully described and figured (partly from CUNNINGHAM'S original specimens at Kew); several new species are described, among them A. Hendleyi and A. Hammondii; and both are figured. A most useful feature in Mr. MAIDEN'S descriptive work is a critical contrasting of the differential characters of allied species.

ON INCREASED FOOD PRODUCTION.

ALLOTMENTS

THE Food Production Department's scheme intended to add 500,000 more plots to the allotments of the country before the end of March is making good progress. In one week recently about 260 acres of land were taken up for allotments, providing nearly 4,000 new plots. Portsmouth has added 1,000 more plots, Newcastle-on-Tyne 420, Ashington (a mining village) 364, and Port of Blyth (Northumberland) 260. It has been stated that one in twenty of the population of Luton (Beds.) is an allotment holder. This is a high percentage, but at Tenby, out of 900 householders, 450 are said to have allotments.

STRINGLESS FRENCH BEANS.

THE pods of the Stringless French Bean possess a character or property that does not seem to be appraised at its full value. During the past summer I purposely allowed the pods of the Climbing French Bean Mont d'Or to hang on the plants for a fortnight or more after they were fit for use. The seeds were fully formed, and almost as large as the mature ones. Even then the pods were tender and buttery after being boiled whole, with only one slender thread at one of the sutures. The seeds could not but have added nutritive value to the dish. The endocarp is wholly devoid of the cartilaginous membrane which makes other French Beans, and Scarlet Runners in particular, stringy and uneatable if not consumed at the proper time. The early flowers and all others of the French Beans are self-fertilising, and begin setting their fruits as soon as they are developed; whereas Scarlet Runners drop their early flowers in large numbers. After the latter begin fruiting they often give a much greater produce than can be consumed at once, and the result is waste. During the past season many of the pods were left on the plants till brought down by frost and wind. Mont d'Or has chrome coloured pods, but there are green podded varieties, both dwarf and climbing. All the French Beans constitute more tender and delicate food than the varieties of Phaseolus multiflorus, and if the stringless ones were introduced amongst the rest they would provide a succession in the event of a glut of the ordinary type, or, in other words, could be allowed to hang on the plants till the excess of the others was overtaken. *J. F.*

THE BUXTON LIME FIRMS COTTAGE-GARDENS ASSOCIATION.

FEW districts have responded more readily or successfully to the demand to grow more food than has that part of Derbyshire within the scope of operation of the Buxton Lime Firms. These firms employ some 1,500 men, and the problem so successfully attacked was to enable these men to provide themselves and their families—some 7,500 souls—with as much home-grown food as possible. To this end the Association was formed, established allotments, and cultivated in addition about 100 acres of vegetables, the work being done by women under skilled instruction; liberal encouragement was also given to school gardens. As a result some 2,000 tons of food were grown where none grew before.

Furthermore, herds of goats were started in two centres, and members were encouraged to purchase the progeny of the herds on a system of easy payments. Rabbits and pigs were also provided on similar terms.

An enthusiastic account of this notable piece of work is given in a little pamphlet* written by Mr. James Clayton, with the object of showing what large employers of labour can do in the way of setting on foot schemes not only of immediate utility, but of permanent value.

THE CULTIVATION OF ONIONS.

A BULLETIN describing the method of cultivation which has proved successful in the Horticultural Department of the Harper Adams Agricultural College, published by the College, gives details of the cultivations employed, together with illustrations of the crop.

Copies of the Bulletin (No. 1918/1A) may be obtained on application to the Principal, Harper Adams Agricultural College, Newport, Salop.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

NATIONAL UNION OF SCIENTIFIC WORKERS.—It is a commonplace nowadays that science does not occupy its rightful place in the national life, and that the interests of its workers receive too little attention from those who direct the State. The originators of the National Union of Scientific Workers believe that the only remedy is for scientific workers to adopt the form of organisation which experience shows to be the most effective for exercising political and industrial influence. This form is that of the great labour trade unions, and of such professional bodies as the British Medical Association and the National Union of Teachers. A close imitation of the policy of any of these bodies is not contemplated, if only because our needs are different; it is the form of organisation that we propose to follow. The originators of the scheme feel that it would be absurd for them, or for any self-appointed body, to lay down at the outset the constitution or the policy of the union. For the present they are confining themselves to setting up a preliminary organisation which will enable a meeting to be summoned which shall have the authority necessary to decide these matters. Accordingly in the pamphlet (for which all who are interested are earnestly requested to write), the chief part is given to a description of this organisation, although indications are also given of the directions in which it is thought that the actions of the union, when formed, are likely to be most effective. Since the policy of the union will not be settled finally until the preliminary organisation is complete, and the general meeting summoned, we would urge that any divergence from the views expressed by the originators is quite as potent an argument for taking part in the preliminary organisation as complete concurrence with those views. *Norman R. Campbell, General Secretary, North Lodge, Queen's Road, Teddington.*

YEW POISONING.—I am interested in the report of the case on "Yew Poisoning" which appeared in the *Gardeners' Chronicle* for January 12, p. 20, but there are questions that I consider require very thorough investigation, which go much deeper than the legal aspect, and which I have never yet seen exhaustively dealt with, though I have often searched for the facts. The poisonous nature of the Yew seems to be generally admitted. The questions are, what part of the tree, in what state of growth or decay, and to what animals is it poisonous—or are there different species or varieties of Yew? Here is my experience. I have positive knowledge of a field in which there are Yews of all ages, unfenced, and in which horses, cows, and sheep have grazed for many years without any record of injury, on the evidence of our familiar friend, the oldest inhabitant. Experienced men of sound local knowledge have not the slightest hesitation in putting their animals in this field; they scout the idea of danger; but they have never been able to explain their confidence, except from use and wont. Personally, my experience of some Yews has gone far to remove my doubts, which I confess were very active at first, though I have never yet had any satisfactory scientific explanation to relieve them. On the contrary, in the adjacent field are several old and well-grown Yews, which are and have been fenced for many years for the express purpose of protection, and one cannot but believe that this must have been done for good reasons, though I have not been able to ascertain their history. From what I have been able to gather from books, I surmise that the injury is usually due to an internal irritation, caused by the animal eating the dried leaves which have fallen from decayed or lopped boughs into the herbage; but I can hardly believe this is an exhaustive explanation. It is, I believe, admitted, and in my own experience I have observed, that animals will readily eat the young shoots in small quantities without injury, and possibly for some medicinal purpose. But I am bound to believe that there must be some condition of extreme danger, whether it is as above or toxic, or depends on quantity eaten, or the species, sex or age of the tree, or season of the year. Now, what is that condition? I hope that some of your contributors who have made a study of the subject will give us the benefit of their reasoned opinions or reference to authority. Accurate knowledge on all matters connected with the economical use of pasture land is obviously becoming more valuable, and I hope you will consider the discussion of this subject worthy of space in your columns. *Puzzled.*

LITIGATION V. ARBITRATION.—"Why do people bring such a case into a court of law instead of getting an expert arbitrator to settle the matter?" asked a learned judge the other day. As nobody ventured to reply to his Lordship's question it is to be assumed that the riddle is insoluble. The case was an interesting one for suburban gardeners. It appeared that the plaintiff accepted, as monthly tenant for his furnished house, a lady, whose husband was on military service. For many years he had devoted himself to his garden, and after twelve years' effort had created a little pleasaunce entirely secluded from any overlooking. Such conditions naturally necessitate a thick screen of trees and shrubs. Unfortunately, the tenant had a great passion for light and air, and in her view the privacy of the garden was too dearly bought in respect of these desirable aids to health. Therefore, after taking possession of the house, she had an interview with the owner, who listened sympathetically to what she had to say, with the result that the lady came away believing herself at liberty to remove all planting which she deemed superfluous. The landlord, on the contrary, was conscious only of having given permission for reasonable pruning and thinning to be carried out. Those who have practised tree-cutting know how insidious is the appetite for using axe and saw. They will appreciate the fierce joy of a lady who, objecting on principle to trees near a house, finds herself at liberty, as she supposes, to effect what she considers to be an improvement. The consequences may be imagined. The tenancy lasted some seven months, and the owner revisited his home anticipating the delights of a spring garden. When he had last seen his house, which was the oldest in the road, it was as a patriarch among its neighbours. The front was then obscured from public view by the long, leafy growth of years. Imagine his stupefaction at the sight of a staring, clean-shaven front which he had thought never to have seen again. The cherished Thorns and Laburnums and Almonds, the kindly Laurel hedge and other aids to seclusion had disappeared. The door-side Jessamine, daily witness of a thousand farewells and homecomings, was cut to the root, and all that remained was tier upon tier of nails in brickwork bearing tags of cloth. The tragedy of the thing burned into the owner's brain, and excusable indignation leaped into flame. The world's worst tragedies spring from the misunderstandings of honest people, because such are unheld by obstinate conviction of right. The explanations and compensation demanded by the owner of the ruined garden were not meekly met, and legal proceedings were the outcome of the affair. We need not follow out the details of the case. At the end of the first day's proceedings the judge asked if it was necessary to indulge in further expense. He hinted that he thought the lady had exceeded her rights as tenant, although the landlord might have taken more trouble to ascertain her intentions. He thought it was to everybody's interest to settle the matter. The suggestion of the learned judge was accepted by the advisers of both parties. The defendant agreed to pay the sum asked as compensation, each side paying its own costs. The case ended with a repetition of the opening enquiry: "Why do people take such cases into a court of law instead of inviting some responsible authority to appoint an expert arbitrator?" I commend his Lordship's advice to all who are tempted to set foot unnecessarily in the snare of litigation. *Anti-Litigant.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 12.—The one hundred and fourteenth annual meeting of the Fellows of this Society was held on Tuesday last in the Council Room of the Vincent Square Hall. The exhibition, as on the occasion of the last annual meeting, was held in the Drill Hall, Buckingham Gate Westminster. The attendance was moderate and there were few exhibits. Orchids were the principal subjects, and the Orchid Committee recommended three First-class Certificates and one Award of Merit to novelties.

The best exhibit in the Floral section was a group of indoor flowers and Ferns exhibited by Messrs. H. B. MAY AND SONS. The Ferns included a collection of hardy kinds, as well as choice exotics. There were also groups consisting of Primula obconica, Cineraria Feltham Blue, and the scarlet-flowered Columnea magnifica, the latter shown as small specimens in pots, flowering profusely. Messrs. ALLWOOD BROS. showed a collection of Perpetual-flowering Carnations, the selection embracing the newest and best varieties.

The other exhibits in this section consisted mainly of hardy plants, including Alpines. Messrs. H. CHAPMAN, LTD., staged seedling Irises, raised from I. reticulata, I. Danfordiae, and allied species; also hybrid Freesias, two of which received Awards of Merit. The variety Market White is of exceedingly robust habit, and produces large trusses of white flowers of a more regular shape than the type. Saxifrages, coloured Primroses, Crocuses, bulbous Irises, Anemones, Daisies and other spring flowers were shown by several exhibitors. Messrs. R. DICKER AND SONS had delightful little plants in pots of Saxifraga Gloria, S. Grieshachii, S. Faldonside, and others. Another excellent exhibit of these popular plants was shown by Mr. G. G. WHITELEGG. The collection included masses of S. apiculata alba, S. Boydii alba, and S. Boydii Gloria, among the finest of early-flowering Saxifrages. Messrs. PIPERS displayed hardy plants and dwarf shrubs suitable for the rockery. The chief features were dwarf Conifers and hardy Cyclamens. Messrs. J. CHEAL AND SONS' exhibit of Alpines included a dark form of Daphne Mezereum, every tiny plant was crowded with its fragrant flowers. Messrs. W. AND J. BROWN exhibited a group of their double white form of Primula obconica, and new varieties showing a little colour, including Marie Queen and Crepe, a crimped picta. Messrs. BARR AND SONS' exhibit of Alpines included species of Crocus such as C. Tomasinianus purpureus, C. corsicus major and the variety Lemon Queen.

The only award made by the Scientific and Floral Committee was a Silver Knightian Medal for a collection of vegetables staged by Messrs. SUTTON AND SONS.

Floral Committee.

Present: Messrs. H. B. May, (chairman), J. Green, G. Reuthe, J. Hudson, A. W. Meerbeim, C. R. Fielder, W. H. Page, C. Dixon, J. Dickson, E. F. Hazelton, W. P. Thomson, J. Hudson, E. H. Jenkins, J. W. Barr, W. B. Cranfield, W. J. Bean, R. C. Notcutt, F. A. Bowles, S. Morris, W. G. Baker, J. T. Bennett-Poe, H. Cowley, W. Howe, J. F. McLeod, F. P. Roberts, C. E. Pearson, and J. Jennings.

FIRST-CLASS CERTIFICATES.

Iris Cantab (see fig. 50).—This beautiful bulbous Iris gained an Award of Merit on February 10, 1914. It belongs to the reticulata group, and bears pale blue flowers, with a touch of mauve; it has a white ground in the throat, and orange-coloured ridge. The plant is hardy, and is easy to propagate. Shown by Messrs. H. CHAPMAN, LTD.

Hamamelis mollis.—This well-known spring-flowering shrub is a native of China, and was discovered and introduced in 1879. It is considered to be the finest of the Witch Hazels, and is especially valuable in gardens on account of its flowering so early (it is often in bloom on New Year's Day). Shown by Messrs. R. VEITCH AND SON.

AWARDS OF MERIT.

Freesia Snow Lavender.—This Freesia is a delicate shade of lavender, and a pleasing colour acquisition to this popular florists' flower.

Freesia Chrysanthi aurantiaca.—This is quite a contrast to the last-named variety, being rich yellow, with shading of orange colour. Both shown by Messrs. H. J. CHAPMAN, LTD.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), W. Bolton, J. Wilson Potter, R. Brooman-White, Arthur Dye, Frederick J. Hanbury, C. J. Lucas, W. H. White, A. M. Bain, J. Cypher, J. E. Shill, T. Armstrong, J. Charlesworth, S. W. Flory, R. G. Thwaites, F. K. Sander, Walter Cobb, Pantia Ralli, E. R. Ashton, Stuart H. Low, and R. A. Rolfe.

AWARDS OF MERIT.

Cypripedium Leeanum Queen Alexandra (*Leeanum Lowei* × *Fairrieanum*).—A handsome hybrid, raised in the collection of Sir Jeremiah Colman, Bart., Gatton Park (gr. Mr. Collier), and shown by Messrs. J. A. McBEAN, Cheshunt. A beautiful flower, and the first white variety of this popular hybrid. The flowers are of fine substance.

Odontioda Memoria F. M. Ogilvie (*parentage Pescatorei* × *Charlesworthii*).—A handsome hybrid, shown by Mr. Ogilvie, The Shrubbery, Oxshott (gr. Mr. Hurcomb). The Shrubbery, Oxshott—One of the finest of Odontiodas, which, while a quite recent strain, is equal in form and size to a good Odontoglossum. The plant bore a spike of seven large flowers of a rich claret red colour, the white ground tint being only visible in the irregular markings on the segment. The lip is white in front, and the yellow crest has a white blotch with red markings.

Cypripedium Leeanum Lowei × *Fairrieanum*.—Shown by Messrs. J. A. McBEAN, Cheshunt. A beautiful flower, and the first white variety of this popular hybrid. The flowers are of fine substance.

AWARDS OF MERIT.

Odontioda Peetersii (*Charlesworthii* × *Solfatara*).—Shown by Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. Collier).—A desirable hybrid, with floral segments of a clear dark violet colour and slight white margin and tips. The well-formed lip bears dark purple blotches before the yellow crest, and the front lobe is white.

FIG. 50.—IRIS CANTAB.
(See Awards by the Floral Committee.)

AWARDS.

FIRST-CLASS CERTIFICATES.

Cypripedium Leeanum Shillianum (see fig. 51) (*Hera* × *Lecanum*).—*Hybridist*, shown by Mr. J. E. SHILL, The Dell Gardens, Englefield Green.—A magnificent hybrid, and one of a very remarkable batch raised at The Dell, including The Baroness, which was awarded a First-class Certificate at the previous meeting. The variety Shillianum has a fine white dorsal sepal, with an emerald-green base and heavy claret-coloured blotching changing to rose in the smaller spotting in the upper white area. The petals are the broadest and most flatly arranged of any of the class, and have a yellowish-cream ground tinged with purple on the upper half, and spotted on the lower. The lip is mahogany-red with a narrow yellow margin.

PRELIMINARY COMMENDATIONS.

Odontioda Dora (*Odm. Ainsworthii* × *Oda Schroderi*), from Messrs. CHARLESWORTH AND Co., Haywards Heath.—A perfectly formed flower of a deep bronzy red colour, the lip white with red blotches around the crest.

Odontioglossum Nora (*illust.*), *comm.* *Hort.* from Messrs. ARMSTRONG AND BROWN, Tunbridge Wells.—A beautiful hybrid of rounded form and rich colour, dark red on rose with a very slight silver-white edge to the petals. The broad lip has a white ground, evenly spotted

over its whole surface was in marked a most unusual feature in Odontoglossums.

GROUPS.

Messrs. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for a group of remarkably well-grown and profusely-flowered Odontodas, Odontoglossums and Cattleyas, including Cattleya Cotto magnifica 'Enid' × Trianaei, a large and richly-coloured flower; Laelio-Cattleya Queen Alexandra, of good form and colour; and Cattleya Triane 'alba'.

Messrs. CHARLESWORTH AND Co. were awarded a Silver Flora Medal for a group of Cypripediums, Odontonias and Odontoglossums. Odontioda Cuvillus (Phoebe × Harryana crispum) a pretty novelty, showing pronounced features of O. Harryanum.

Messrs. J. CYPHER AND SONS, Cheltenham, were awarded a Silver Banksian Medal for a group of Cypripediums, Odontiodas, Odontoglossums and Cattleyas, including Cattleya Cotto magnifica 'Enid' × Trianaei, a large and richly-coloured flower; Laelio-Cattleya Queen Alexandra, of good form and colour; and Cattleya Triane 'alba'.

Messrs. CHARLESWORTH AND Co. were awarded a Silver Flora Medal for a group of Cypripediums, Odontonias and Odontoglossums. Odontioda Cuvillus (Phoebe × Harryana crispum) a pretty novelty, showing pronounced features of O. Harryanum.

fortnightly meetings, and he wished, in the name of the Council, to thank all who thus helped to maintain the quality of the meetings, which had been held for more than a hundred years. The thanks of all were due to Sir Albert K. Rollit for securing the recognition by the University of London of the Degree of Horticulture.

Sir Harry J. Veitch seconded the adoption of the report, observing that he would add a few words on the subject of the financial position. There was one item which was in abeyance, and seemed likely to remain so until the end of the war, and that was the rent which they would receive from the Government for the Hall in Vincent Square, which had been taken over for the accommodation of Australian troops. No arrangement as to remuneration had yet been come to with the Government, but it was hoped that the sum paid would be a considerable one, and would enable the accounts of the Society for the year to show no loss. The Society had issued about 40 pamphlets on different subjects, all of which were much sought after. He would call attention to the fact that there was one slight error in the printed statement. The number of Fellows of the Society was given as 13,259, but it should be 13,851. The number was fast increasing; at the first two meetings of the year more than 200 Fellows were elected, and, as the president had already remarked, 76 were elected at the meeting held to-day. With reference to investments, last year it was resolved at the annual meeting to increase the amount of War Loan stock held by £10,000. This was done, but it was found necessary in the autumn to realise £17,000 of this stock to meet current expenses, leaving £3,000 still held. A slight loss was made over this transaction, but even then the price had been higher than it was at present, and the sale had enabled the Council to pay off an advance which had been made by the Society's bankers, thus freeing the Society from debt of any kind. Altogether, the accounts were in a healthy and satisfactory condition, taking into account the difficulty of the present circumstances.

Mr. R. J. Wallace took exception to the action of the Council in selling the War Loan stock. He considered that the whole £20,000 should have been held, and that in a couple of years it would have been possible to pay off the bank balance and discharge all liabilities.

Sir Harry Veitch, in reply, said that the Council considered it desirable to have a certain sum available in case of any sudden emergency, and they had only sold out sufficient for this purpose. It was true that a small sum had been lost on the transaction, but if it had been carried out later more would have been lost. The Council had wished to end the year out of debt, and so thought it better to pay off the bank debt of ten thousand pounds and start with a clean slate, besides settling an outstanding liability in connection with the Wisley garden.

The report was adopted unanimously.

Mr. C. E. Shea moved that the Fellows record their emphatic protest against the decision of the Food Controller that no sugar be distributed this year to private fruit growers for the purpose of making jam, and approving the memorandum addressed by the Council to Sir Charles Bathurst (see p. 69). The secretary then read the memorandum referred to, and Mr. Shea continued that the Fellows were there to support this action of the Council. It had been admitted that the submarine sinkings of sugar had been rather less serious lately, and that the stocks of sugar in the country were, if anything, larger than they were last year. It was freely said that the large jam factories were getting all the sugar, to the detriment of the private grower and the small fruit-farmer. The plan of collecting all the fruit from the small growers and making it into jam and preserve in central factories was quite impracticable and doomed to failure, and would mean the complete loss of enormous quantities of valuable food. Mr. A. W. Oke seconded the motion, and suggested that the Council send a deputation to the Sugar Controller on the matter. The Rev. G. H. Engleheart supported, and said that although the Society should not offer any captious criticism, yet they should be willing to place their accumulated knowledge and experience at the disposal of the Sugar Controller in this matter. He had noticed in the latest pronouncements emanating from the Sugar Control signs of giving way, and believed that Lord Rhondda was himself sympathetic towards the private fruit-grower. Mr. W. H. Page also supported the motion, which was carried unanimously. The suggestion of Mr. Oke that a deputation be sent was put in the form of a resolution, and carried, the deputation to consist of Mr. C. E. Shea, Sir Albert K. Rollit, Mr. A. W. Oke, Mr. James Hudson, Rev. W. Wilks, and Mr. Owen Thomas, with power to co-opt if desired. At this point of the proceedings the President announced that, owing to Parliamentary duties, he was obliged to leave the meeting, and Sir Harry Veitch took the chair.

Sir Albert K. Rollit moved that a special vote of thanks be passed to the Rev. W. Wilks, who had been a Fellow of the Society for fifty years, and secretary of the Society for thirty years, on that day. Sir Albert referred to the very special and strenuous exertions which had been put forth by Mr. Wilks and his staff during the last three years, owing to the extra work occasioned by the war conditions, and by the fact that it was almost impossible to obtain adequate assistance.

The motion was carried with acclamation.

Mr. Wilks, in replying, said that he thanked Sir Albert and the other Fellows present most heartily for their generous praise, and testified to the loyalty and devotion of the members of the staff, who had certainly worked inordinately hard. The Society was unable to obtain more assistance, and if help had been obtainable they would have no choice to accommodate extra staff. The time must be close at hand when the Fellows would have to look for a new secretary, and he trusted that whoever they chose would be able to get up in thirty years' time and say, as he himself could say, that he had had the happiness of being secretary to the most united and pleasantly conducted Council that could be found.

The chairman then handed the Victoria Medal of Honour to Mr. W. J. Bean, Mr. F. J. Chittenden, Dr. A. B. Rendle, and Sir Albert K. Rollit.

A vote of thanks to be conveyed to Lord Grenfell for his presidence closed the proceedings.

ROYAL GARDENERS' ORPHAN FUND

FEBRUARY 8.—The annual general meeting of the subscribers to the Royal Gardeners' Orphan Fund took place at Simpson's Restaurant, 100, Strand, London, on the 8th inst. Mr. Edward Sherwood presided in place of Mr. H. B. May, who was unfortunately prevented from attending owing to indisposition, and it was agreed that a note be sent him expressing the sympathy of the members, and their hope that he would shortly be fully recovered. The secretary, Mr. Brian Wynne, read the notice convening the meeting, and the minutes of the last annual general meeting, which latter were duly confirmed. The report of the committee for the year 1917, which had been circulated to the subscribers, was taken as read. The following extracts from it refer to the more important items:—

EXTRACTS FROM REPORT OF EXECUTIVE COMMITTEE.

In spite of the indebtedness to the Bank of £800 the Fund is in a healthy condition. The subscriptions, donations and other contributions received during the year have exceeded general expectations, while the working expenses have been considerably reduced. Your Committee would gladly welcome any help towards discharging the debt owing to the Bank.

The 69 Beneficiaries of the Fund were being received at the commencement of the year by 107 children, and, as in the previous year, 16 candidates, all of whom, in accordance with rule, had been receiving half allowances, while voting for election were added to the list at the annual meeting. Nineteen of the children ceased to receive the weekly allowance during the year, and most of them were subsequently given extra grants towards providing an outfit on commencing to earn their own living. These gifts are included in the item which appears in the accounts as "Grants in Aid." The amount disbursed in allowances during the year was £11 5s. less than in the previous year, while grants in aid also show a decrease amounting to £13 13s. 6d. At the ensuing annual meeting the Committee recommend the election by resolution of the 14 candidates.

The special appeal for help to assist the Committee in carrying on the beneficent work of the Fund which was made by the treasurer in May was not quite so successful as in previous years. Your Committee, however, most gratefully acknowledge the gift of £500 from Messrs. Hurst and Sons, an appreciable sum from the treasurer to level up the investment in 5 per cent. War Stock to £1,100, a certificate for a 5 per cent. War Loan Bond from a lady supporter, and generous gifts from Messrs. Sutton and Sons, Sir John E. D. Hawkyns, Bart., Mr. Whitborne Nutting, Mr. R. Gee, Esq., and Miss Flower. Generous subscriptions and donations were also received from Sir Frank Crisp, Bart., Messrs. Rothschild and Sons, and Mr. Ernest Sowerby. Your Committee gratefully acknowledge their continued thanks. The Bournemouth Gardeners' Improvement Society, the Altrincham Gardeners' Improvement Society, the Scottish Horticultural Association, the Dumfries and District Horticultural Society are most cordially thanked for their kindly efforts on behalf of the Fund, as are also the honorary local secretaries, especially Mr. George Carver, Mr. F. Nash, and Mr. W. Rowe, to whose kindly efforts the increased receipts from local secretaries are mainly due.

Your Committee deeply regret to record the heavy loss which the Fund has sustained during the past year by the death of three of its Correspondents, Sir James Whitehead, Bart., Mr. Leopold de Rothschild, C.V.O., and Mr. William Marshall, V.M.H., also a more than usually lengthy list of deceased generous supporters. To the initiative of Sir James Whitehead was entirely due the inauguration of the Annual Dinner, from a comparatively small yet only slightly remunerative function to the series of most successful annual festivals. Mr. Marshall was elected a member of the Committee in 1890, and for the following ten years was annually re-elected chairman. Other valued helpers whose services to the Fund will not soon be forgotten are Mr. Arthur T. Ware, whose gifts of flowers so often helped to adorn the tables at the Annual Festival, Mr. John Margetson, Mr. George Bunt, Mr. Thomas Jeffreys, Mr. H. Richardson, Baron de Sonnebelhe, M. Philippe L. de Vilmorin, Mr. James Hudson, Mr. A. F. Vinden, and Mr. A. McVinish.

The members of the Committee who retire by rotation are Mr. W. Bates, Mr. W. H. Divers, Mr. C. Dixon, Mr. J. McKerchar, Mr. H. B. May, Mr. J. W. Moorman, Mr. W. Nicholson, and Mr. George Reynolds, all of whom offer themselves for re-election.

Mr. Reader, your Committee deeply regrets, cannot see its way to continue to act as one of the auditors, owing to the pressure of other engagements. He therefore has to ask to be relieved on and on his retirement the Committee desires to place on record its high appreciation of his past services. Mr. W. A. Bilney, J.P., has kindly consented to fill the position vacated by Mr. Reader, and the committee has very great pleasure in recommending his election.

THE ROYAL GARDENERS' ORPHAN FUND.

CASH STATEMENT FOR THE YEAR ENDING DECEMBER 31, 1917.

RECEIPTS.

The Chairman, in moving the adoption of the report, said that the overdraft at the bank of £600 was in consequence of the adverse conditions brought about by the war. The special appeals had not brought in as much money as was hoped, and had not compensated for the omission of the annual festival dinner. The fund had received two legacies during the year, but it behoved everyone to make a great effort to help to clear off the overdraft and get the Fund once more on its former sound footing.

Mr. Poupart seconded, remarking that it was something to be thankful for that the Fund, though short of money, was able to continue its good work. The report was adopted.

Mr. Poupart then moved that the resignation of Mr. Frank Reader, one of the auditors, be accepted with great regret, and that he be thanked for his past services. This was seconded by Mr. J. W. Moorman, and adopted.

Mr. J. McKerchar moved that Mr. W. A. Bilney, J.P., be elected auditor in place of Mr. Reader. This resolution was seconded by Mr. Leech, and carried.

Mr. J. F. McLeod then moved that Mr. Edward Sherwood be re-elected treasurer, and thanked for his past services. The resolution was seconded by Mr. J. W. Howe, and carried unanimously. Mr. Sherwood replied briefly, expressing pleasure at his re-election, and avowing that there was very little work connected with his office, though there was at times a certain amount of anxiety as to the state of the funds. Mr. McLeod moved that the retiring members of the committee, namely, Messrs. W. Bates, W. H. Divers, C. Dixon, J. McKerchar, H. B. May, J. W. Moorman, W. Nutting, and George Reynolds, be re-elected *en bloc*, which was unanimously agreed to.

Mr. Sherwood moved that Mr. Brian Wynne be re-elected secretary at a salary of £200 per annum, remarking that the members of the committee had the greatest confidence in Mr. Wynne, and felt that they could not have a secretary who had the interests of the society more at heart, or who was more zealous in its service. The motion was unanimously carried, and Mr. Wynne made a suitable reply.

Mr. Sherwood then moved that the fourteen candidates before the committee should all be placed on the funds. Their names are as follows:—Chilton, James Harold; Dodd, Margaret; Haslett, Albert Victor; Haslett, Frederick Ian; Hobbs, Rose Mary Grace; Hubbard, Kathleen; Hubbard, Stanley; McCallum, Alan Fielder; McCallum, Gladys Edith; Reeve, William Herbert; Robinson, Charles Kenneth; Robinson, Victor; Sleigh, Daniel James; Sleigh, Mary Elizabeth. This was unanimously agreed to. The chairman announced that he had received a letter from a lady, Mrs. Ward, offering the sum of £15 a year for the support of the candidate Victor Robinson, and enclosing £12 for the remainder of the present year. It was agreed that the offer be accepted, and that a letter of thanks be sent to the donor. A letter had been received from Mr. H. B. May thanking Mr. Sherwood for taking the chair in his place, and for his labours as treasurer of the Fund. A resolution to this effect was proposed and carried, and Mr. Sherwood replied that it had been a great pleasure to preside over the meeting, though he hoped that on the next occasion Mr. May would be well enough to be there himself. The Fund was a subject very near his heart, and he trusted before very long to see it again on its former sound footing.

CROPS AND STOCK ON THE HOME FARM.

SEEDS FOR SPRING-SOWN CROPS.

Owing to various causes, and especially unfavourable weather at the time of harvesting seed last summer, there is likely to be a scarcity of some kinds of seeds.

I would strongly advise that all orders should be placed in the hands of seedsmen at once to ensure the best delivery possible.

With a view of assisting the inexperienced I give the quantities required per acre in their various sections for spring sowings.

Turnips and Swedes 2 lbs., Mangold 8 lbs.; Clover (Broad Leaved) 15 lbs.; Italian Rye Grass, when sown with Clover to increase the yield of hay should be used at the rate of half a bushel per acre. If sown as a crop of green grass for sheep when weaning lambs, for which purpose it is excellent, 1 bushel per acre will be required. Trefoil, or suckling Clover, more commonly known as Black seed, which is useful for mixing with Italian Rye Grass for sheep food or hay, should be sown at the rate of 6 lbs. per acre. Spring or winter Vetches, 2 bushels; Maize 1 bushel when grown for milk cows, of the Horse-tooth variety.

Rape, when sown broadcast, 6 lbs.; when drilled 4 lbs.

Sugar Beet, 6 lbs.

Onions, 8 lbs.

Trifolium, when sown on rich soil, 20 lbs.; on moderately rich soil, 30 lbs.

Barley, 3 bushels.

Oats, 4 bushels (sometimes 5 bushels are used).

Cabbage for cattle if transplanted, ½ lb.; if drilled for permanent growth, 3 lbs.; Carrots, 7lbs.; Parsnips, 7 lbs.; Lucerne, 20 lbs.; Peas, 3 bushels.

Potatos, 14 cwt. of tubers weighing from 1 oz. to 2 oz. each.

Sainfoin, 4 bushels.

ONIONS.

The most suitable soil for Onions is a deep, stiff loam. Where convenience exists the plants should be raised in cold frames, sowing the seed in boxes early in February, hardening the seedlings thoroughly, and transplanting them 4 inches apart in rows made 1 foot apart in April. The earlier germination of the seed under glass assures a quicker growth, and the plants escape attacks of the Onion fly. If not already done, no time should be lost in manuring and ploughing the land, following with a subsoil plough to ensure deep cultivation. A second ploughing crosswise early in March will improve the tilth for planting and the sowing of seed in the open.

EARLY GRASS.

Italian Rye and Trifolium incarnatum are making rapid growth. Remove all Docks and well roll the plot to press stones below the reach of the grass-cutter as well as solidifying the soil about the roots of the grass, which, after frost, is often loose and not in favour of free growth.

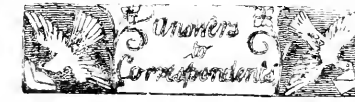
Where the grass is pale in colour sow evenly over the plot 1 cwt. sulphate of ammonia per acre, or 3 cwt. of superphosphate of a strength not less than 30 per cent.

STIMULATING THE WHEAT CROP.

If there is any suspicion that the land is not in good heart to carry the Wheat crop to a successful issue, and the plant appears weak, sow 1 cwt of sulphate of ammonia per acre during the present month. *E. Molyneux.*

Obituary.

THOMAS WILSON.—We regret to record the death, on the 24th ult., of Mr. Thomas Wilson, for some twenty years gardener to Lady Strathmore at Glamis Castle, Forfarshire. His death was due to the after-effects of an operation which he had to undergo last November. Deceased was a skilful gardener, and designed and laid out several portions of the gardens at Glamis Castle. He was also entrusted with the laying out of Lady Strathmore's gardens at Inchdownie Cova. He leaves a widow, one son, and three daughters.



MOSS ON LAWN: *I. M. T.* The fact of the soil of your lawns being sandy, and getting very dry in summer, would not account for the presence of the moss. It is probable that the subsoil is improperly drained, and that water, although it percolates quickly through the surface, collects and stagnates just below. Your first step, therefore, should be thoroughly to drain the ground. Endeavour to favour the growth of the grass by applying a nitrogenous fertiliser, such as sulphate of ammonia, in the spring. Apply it at the rate of about 1 oz. to the square yard, at intervals of a few weeks.

NAMES OF PLANTS.—*Correspondents not answered in this issue are requested to be so good as to consult the following number.*

Conifers, Co. Longford. All seedling forms of Cupressus Lawsoniana, which is a very variable plant, hardly any two being exactly alike in a bed of thousands of seedlings. A number of the more distinct forms have received varietal names, but your plants are roughly typical of the species, though No. 1 is very near var. pendula.

POTATOS DISCOLOURED: *W. S.* The tubers are affected by the disease known as "sprain," an obscure complaint which causes discoloured rings inside. It does not affect their cooking properties or taste, and "sprained" tubers may be used for seed, but you will scarcely require to use them for this latter purpose.

PRIMULA MALACOIDES: *J. W.* So far as is known, the foliage of Primula malacoides does not cause skin irritation, as in the case of P. obconica.

ROAD SWEEPINGS AS MANURE: *C. A. O.* If you are sure that the road sweepings are free from tar, petrol, and motor oil, you should scatter the manure on the ground. Leave it to dry thoroughly, and then rake out of it all the sticks and paper into a heap and burn them. If, however, you have reason to think there is petrol in the mass, make it into a compost as you suggest. Place it in a heap with a fork, and get out of it with the fork as much of the paper and other useless material as possible.

SUNFLOWERS: *C. W. M., Morpeth.* The average yield of Sunflower seeds in Russia, where they are extensively grown, is about fifty bushels of seed to the acre. As a general rule, 100 bushels of seed will yield thirty-three bushels of kernels. The average yield per head varies, and it would not be difficult to experiment on a small scale to arrive at the yield to be expected in this country. For the production of Sunflower oil, the Russian Sunflower, a large-seeded variety, pr ducing a single head, is the best, but for kernels, which are largely eaten in Russia, the small-seeded kinds are grown.

TOMATOS: *T. G.* Tomato seeds should be sown in a compost consisting of one-half loam and one-half leaf-mould or manure from an old Mushroom-bed. The seeds should be dibbled in separately, 1½ inch apart and ¼ inch deep. From your description of the seedlings, it is evident that you are keeping them in too damp and close an atmosphere; they need plenty of ventilation. Pull out the seedlings which have "damped off" and sprinkle sand and powdered charcoal on to the space where they have been; then place the seed pan on a high shelf near the roof-glass of the house where they are growing, so that they may be in a dry place and receive the maximum of light.

VAPORISER: *C. L.* The article you mention can be used for the fumigation of all plant houses where the plants are liable to attacks of mite or red spider. The address is Lund Street, Cornbrook, Manchester.

EARLY SPRING FLOWERS.

IT is astonishing how quickly the earliest spring flowers respond to a slight rise in temperature after a spell of cold weather. From the middle of December to the middle of January the soil was almost continually frozen on the surface. On January 14, and again on January 17, we had three or four inches of snow, and yet on the 27th four different Irises and nearly twenty different Crocuses were in full flower in the open.

The first Iris to appear was I. histrioides. The true plant comes from the neighbourhood of Amasia, in Northern Asia Minor, and large flowers measure over 4 inches across, while the blade of the falls is just over an inch in breadth. The colour is generally a deep blue of the shade that the Repertoire de Couleurs calls steel-blue (230, I.), though in some flowers the colour is distinctly paler. The centre part of the blade is blotched with this colour on a white ground, and there is a central, raised ridge of orange. This Iris seems to succeed in the light sand of my garden enriched with leaf-soil and old manure better than most of the other members of the reticulata section. The bulbs should be lifted and replanted after a short interval every few years, or whole colonies sometimes fall victims to disease and die outright.

The next Iris to appear was a southern relative of histrioides of a distinctly redder shade of purple, with falls curiously mottled with two shades of the same colour. It is one of the many forms of this iris which come from further south in Asia Minor, and which are usually supplied by the trade as histrioides instead of the true plant. These forms are neither so large nor so sturdy as the type, but they respond to the same treatment and are very welcome early in the New Year.

On January 27 the first flower of I. Rosenbachiana (see fig. 32) appeared, with its astonishing combination of white and crimson and gold. Like most Turkestan Irises, it seems to like this sandy soil, and for some years now I have been able to save seeds and raise seedlings annually. I like, if possible, to grow the plants in a cold frame which is kept closed in summer and uncovered all the winter, until the flowers appear. Then for a month or more there are always flowers to be seen, for strong bulbs send up three flowers in succession.

The fourth Iris was a remnant of a batch of hybrids of I. Bakeriana and I. reticulata which gave me some exquisite little plants, most of which, I am sorry to say, I have lost through inattention and lack of time since 1914.

Early Crocuses have one advantage over early Irises. Once an Iris flower has expanded, it remains open and a prey to any vile weather. It is, therefore, best to pick the buds and stand them in low bowls filled with damp sand. Crocuses, however, open to the sun, but close when the sun

FIG. 32.—IRIS ROSENBACHIANA. See text.

goes in and keep their flowers unspotted until the sun shines again.

My earliest Crocus, with golden yellow flowers, is apparently the C. Olivieri of Gay, according to Maw's monograph. It is remarkable for its broad leaves, which appear with the flowers. Crocus Imperati, with its pinkish-purple flowers and striped backs to the petals, was out even before the snow came, but its mill-white albino form with a golden base waited for the disappearance of the snow.

The great disadvantage of Crocuses is that they can only be distinguished by rooting up the plant and inspecting the coats of the corm, and by pulling the plant to pieces in order to count its real and basal spathes. Thus I have at present three or four golden-flowered Crocuses which I hesitate to name, though I suspect them of being forms of C. aureus. C. gargaricus is even deeper in colour; and a form of C. Balansae, which I owe to the generosity of Mr. Bowles, has three golden inner petals, but the outer three so heavily coloured on the exterior as to be a deep mahogany. The contrast is very striking.

C. chrysanthus is easier to identify, though the colour of its flowers is usually not golden. The distinguishing mark is to be found in the black tips of the base of the anthers. This feature is present in the true butter-yellow form that Van Tubergen named after Mr. Bowles, and also in the Leeds's variety, Bullfinch, which has white flowers heavily veined externally with dark grey.

The species of C. biflorus are very numerous, and one of them is known as the "Scotch" Crocus. Others are pure white when open, but have beautiful blue-grey backs to the petals.

All of these Crocuses are of the easiest possible cultivation in well enriched light soil, but they must have a sunny position, where they have the best chance of opening whenever the sun does favour us in January and February. *W. R. Dykes, Charterhouse, Godalming.*

ORCHID NOTES AND GLEANINGS.

ODONTIODA MEMORIA F. M. OGILVIE.

THE hybrid Odontioda illustrated on p. 81, fig. 35, of which the parentage is unfortunately unrecorded, was awarded a First-class Certificate by the Orchid Committee at the meeting of the Royal Horticultural Society on the 12th inst. The plant is a worthy representative of the excellent cultivation and fine quality of the Orchids acquired by the late Fergus Menteith Ogilvie, Esq., and is well worthy of its place in this important collection.

CYMBIDIUM SHILLIANUM.

FLOWERS of Cymbidium Shillianum, a cross between C. Holfordianum (eburneum × grandiflorum) and C. Pauwelsii 'The Dell' variety, are sent by the raiser, Mr. J. E. Shill, from The Dell Gardens, Englefield Green. They are large and of wax-like substance, showing much of C. eburneum in the clear white, for the green tints of both C. grandiflorum and the C. Lowianum in C. Pauwelsii are entirely eliminated. The only colour in the flower is a pale yellow shade at the bases of the petals and on the column, and rose-red blotches inside the margin of the lip. A line of rose-red also runs from the crest to the front of the lip. Hybrids of its class are now very numerous, and there is a certain resemblance between the results of some different crosses, but all vary in some respects.

ODONTIODA BRADSHAWIAE.

WE have received from Mr. Balmforth, gardener to Mrs. Ogilvie, The Shrubbery, Oxford, a very singular abnormal development of flowers of Odontioda Bradshawiae (O. crispum × C. Noezliana), in which three joined flowers present a seemingly double bloom 4 inches across and bearing some resemblance to a decorative scarlet Dahlia. The flattened pedicels joined together disclose the amalgamation of three flowers on one stalk, which carries on the joined columns, each with its more or less perfectly formed labellum, into the centre of the flower. From the centre spread in tolerably regular order the fifteen segments forming the sepals and petals of the flowers, and most of these are fully developed. The scarlet ray of segments bears the yellow crests of the lip, one of which is quite perfect in the centre.

ODONTOGLOSSUM CRISPUM JOHN HARTLEY.

A FLOWER of this fine Odontoglossum, which secured a First-class Certificate at the meeting of the Manchester and North of England Orchid Society on the 7th inst., is sent by John Hartley,

Esq., The Knowle, Mobberley, Cheshire. The variety is one of the most beautiful forms of O. crispum which has yet appeared, and is of the same class as O. crispum Ashworthii, for which the Davidson Cup was awarded at the Chelsea Show of the Royal Horticultural Society, May 25, 1915. The variety John Hartley has nearly equal sepals and petals, which expand to 3 inches in width. The ground colour is white, tinged with yellow from the colouring on the reverse side, but the greater part of the surface is covered with ruby-red blotches, the tint of which is heightened on the well-displayed fringed petals. The lip is white, with a fringed margin, and there are red-brown blotches around the basal yellow crest. The segments, as in many other highly developed forms of O. crispum, is dorsally inclined to be upper-side.

CATTLEYA TRIANAE.

MR. WILLIAM PLACE, Wildespool, Warrington, sends two fine spikes of flowers taken from plants of an importation of Cattleya Trianae. The colour in one of the variable and widely distributed species, with pale lilac sepals and petals and purple-fronted lip. The other flower exhibits quite new features for the species, and is in effect intermediate between C. Trianae and C. Mendelii. The sepals and petals are tinged with rosy lilac, with fine white veining. The lip, which is more elongated and crimped than in ordinary C. Trianae, is rose-purple in front and lighter in tint at the base and edges of the side lobes, the prominently distinct feature being a closely arranged series of yellow branched lines running from the base to the front lobe, and two pale yellow patches, one on each side of the opening of the tube.

RHODODENDRON PARVIFOLIUM.

RHODODENDRON PARVIFOLIUM (see figs. 33 and 34) is, in the mild days of early and mid February, a very valuable plant. In the Cambridge Botanic Gardens the plants grow nearly 5 feet high and are covered with little clusters of from four to six bright rosy-purple flowers. The species is described by Mr. Watson in *Rhododendrons*, Present Day Gardening Series, as an erect, ericate shrub, with leaves oblong, scaly, green above, rusty beneath, ½ an inch long. They are slightly aromatic when crushed, and the plant is evergreen. The flowers are ½ to ¾ inch across, and suggest those of R. anthopogon, but that, perhaps, is chiefly because of a similar colour. In the Edinburgh Botanic Garden the practice is to peg down the stems and cover them with soil, when they root into it and produce a much better furnished specimen than is otherwise possible. The species is allied to R. lapponicum, illustrated in the *Botanical Magazine*, tab. 3106, but it differs in the stamens, the filaments of which are hairy at the base, and the growth is not procumbent. R. parvifolium makes a good companion to R. praecox, which is already swelling its buds, and preparing to succeed a while later. It is flowering here with R. dauricum, which is said to be earlier, and resembles R. praecox to a great extent, but differs in smaller flowers and in not being erect. It is a native of Siberia, Korea, etc., and is perfectly hardy. For the photograph from which the illustration was prepared I am indebted to my foreman, Mr. F. G. Preston. *R. Irwin Lynch.*

FIG. 33.—RHODODENDRON PARVIFOLIUM IN THE CAMBRIDGE BOTANIC GARDEN.

TREES AND SHRUBS.

HAMAMELIS MOLLIS.

THE history of this beautiful Witch Hazel, which was awarded the R.H.S. First-class Certificate on the 12th inst., is interesting. The species was discovered and introduced in 1879 by Charles Maries when travelling in China on behalf of Messrs. James Veitch and Sons. Plants were grown in the Coombe Wood nursery of the firm for twenty years or so without attracting particular attention. Eventually the late Mr. George Nicholson, of Kew, brought the shrub prominently into notice, and there was soon a considerable demand for Hamamelis mollis, as the beauty of the older kinds of Asiatic Witch Hazel had by that time led to their being extensively planted. Though all the species are beautiful, H. mollis is generally regarded as the finest. It is remarkable that a large number of winter or very early spring flowers are yellow. For example, besides this Hamamelis we have Barberries, Forsythias, Jasminum nudiflorum, the Winter Aconite, Narcissi, and Crocuses, all with yellow blossoms. *W. T.*

FLORAIRE, GENEVA.

ONE hot day at the beginning of last July found me knocking at the door of the simple little home of M. H. Correvon, the friend of all true flower lovers, who gives the warmest of welcomes to anyone from England. His house faces the Alps, and, hidden in the blue depths of the mountains, is his Alpine garden, which, owing to the exigencies of war-time, few can now visit but himself, and he but rarely.

His home garden -Floraire—was a riot and tangle of colour.

Close to his door, and creeping everywhere, was little Heeria elegans, a large-flowered Mexican plant of grey magenta, and a long "dry wall" was covered with the pale blue Borago, showing to greatest advantage so grown. Here also was Stachys corsica, running or creeping everywhere, with white flowers; Androsace foliosa, pinky-white; a Saponaria from Cyprus, and everywhere was Acantholimon venustum, a mass of rose-pink flowers 6 inches high. Here, too, was the lovely Lavatera maritima—pink, with grey foliage. This, with Teucrium orientale, Oenothera caespitosa, and Eryngium florairiense appealed to me more forcibly than anything else for beauty of colour and for decorative purposes. The Teucrium, with lovely deep mauve little flowers like Linaria, was of graceful branching upright form 12 inches high, and deeply cut and greyish foliage. The Oenothera was growing magnificently, the pink flowers deliciously scented, while the Eryngium was the result of crossing E. alpinum and E. Bourgatii, of much finer purple colouring than we usually see in Eryngiums, and which M. Correvon secured in his wanderings. Near to the dry wall was the Opuntia collection—not in bloom, and altogether too prickly and learned for me, but a Scabiosa Pterocephala near by I admired much. A shady alley was bordered by rampant, headstrong Clematis vines. One called Mdme. Julia Correvon originated in the

garden, with velvety crimson blooms 2 inches across.

At Grenoble M. Correvon had found an Astragalus, with Vetch-like leaves 12 inches long, of a bright green, and pale yellow, fuzzy-headed flowers, rather like a Phlomis, but in heads, not whorls. It made a strikingly handsome and spreading plant for a specimen bed.

Morina longifolia had prickly and Acanthus-like foliage with a delicious scent of lemon, and long spikes of pale pink and white flowers in whorls. Rudbeckia maxima, with large pale yellow flowers and very glaucous leaves, was very showy.

Campanula alliariaefolia, with single white flowers, was shown off well by a background of blue Anchusa seedlings, and Campanula persicifolia, in a double variety, was exceedingly pretty, the doubling having turned the bell into a flat flower with four rows of petals, and it had not been spoiled by the doubling, as is usually the case. Next to it was the rare Linum hirsutum, growing 18 inches and 2 feet high and very beautiful.

Pontederia cordata, an aquatic with many spikes of flowers, was attractive, and so was a Cherry tree, Bigarreau jaune. I have said before it was a hot day; the fruit was yellow and very sweet and refreshing, and it is the one Cherry in Switzerland that the birds will not touch. I think it would be worth trying in this country to this end. Pentstemon Digitalis was very charming pale pink flowers with yellow and brown tracery inside, and woolly buds.

A long border of Gentians must have been a wonderful sight when the flowers were at their best. There were still a good many in bloom at the time of my visit. Among them were Gentiana phlogifolia, flowers of richest blue, with Phlox-like leaves; G. Wahlbergi, G. tibetica, G. dahurica, and G. Cruciata.

Here I was obliged to tell him of the exquisite little Gentiana Farreri that Professor Balfour had shown me at Edinburgh, flowering in the rain instead of shutting up, like all other well-conducted Gentians do in wet weather. Dianthus Courtoisi I specially marked. A hybrid, found by M. Correvon at Davos, it grows 1½ foot high even in dry soil, and is rose-pink in colour. One of the gems of the garden was Viola flourieriensis, a mauve hybrid obtained by crossing two Alpine species. The plants I saw had flowered without ceasing for five years in the same place; they are never without bloom from January 1 to December 31. This should be a very valuable plant in English gardens, and I hope to grow it, together with the new rose-colored Primula flourieriensis "Sugelia mooreanda" was very pretty, the blooms dark crimson with golden lips.

M. Correvon waxed enthusiastic over some beds arranged for sub-irrigation. "These," said he, in his quaint English, "are what I call my 'love beds,' and alone are my great treasures." However, there was little show, but had I been earlier I should no doubt have waxed enthusiastic also.

I saw the rare, tiny Rosa berberifolia; a Peganum with a pretty little white flower; Inula ensifolia, from Trieste; Hypericum Coris, pretty, neat foliage and small yellow flowers; Stachys glutinosa, a small plant or herb with insignificant little white flowers, and exquisitely scented when the leaves are bruised; Valeriana flourieriensis, whitish; Dioscorea caucasica, a rare and elegant large-leaved climbing plant; Astragalus alopecuroides; Digitalis lanata and Genista horrida, a dwarf plant like a tiny Spanish Broom, end my list of plants that specially interested me. Space forbids my mentioning the herbaceous plants, flowering so vividly in that sunny spot, where two varieties of the Matilija Poppy were blossoming as profusely as if this were California! I have written too much, but a charming note from M. Correvon to-day, enclosing me some Viola flourieriensis seed, has set me delving into the recesses of my memory and my note-book, while guns are firing all over and round my house, an air raid being in progress. It is well that we have pleasant memories to look back on, even amidst the clatter of shrapnel and the booming of the guns.—*Alpe Mercantour.*

THE ALPINE GARDEN.

SAXIFRAGA BURSERIANA MAJOR.

WITH the dawning year one begins to look forward to the flowering of Saxifraga Burseriana major. It is, with me, generally the earliest of the Burseriana varieties, of which we have two or three. It has often bloomed in January and February, sometimes to its own undoing, as in severe frosts its white flowers have been ruined, while sleet, rain, and snow have also attacked it to its disfigurement. It is, therefore, worth while to give the plant protection. A cloche or bell-glass, tipped on one side to admit air, is helpful, and even a sheet of glass, just a little elevated above the flowers, is a sufficient safeguard. This shelter should be placed over the plants in good time, as even the dainty red buds, thick set on the charming grey, spiny foliage, like a rough carpet, will suffer in severe weather.

FIG. 51.—RHODODENDRON PARAVOLUM: SHOWING FLOWERS AND FOLIAGE, NATURAL SIZE.

(See p. 76.)

MORISIA HYPOGAEA.

MORISIA HYPOGAEA is a small plant in point of stature, but often grows into a spreading tuft of curiously cut polished green leaves, with good-sized, bright yellow flowers. This Alpine likes a poor, gritty soil, as it becomes too big and untidy-looking in rich compost. I have always found that it does best in full sun, and in soil where rain drains away rapidly. It has a curious way of resenting [illegible] in some gardens, and of bidding fair [illegible] but in most cases it may be [illegible] which are "easy" to [illegible]

CAMPANULA RADDEANA.

CAMPANULA RADDEANA, which comes [illegible] Caucasus, is easily increased by division, and soon spreads to a moderate degree without becoming woefully aggressive. I am not aware if seed is produced and ripened, but they may probably be [illegible] by specialists in such plants.

In [illegible] conditions this Bellflower never fails to give satisfaction. Grown in a soil not too heavy nor of a poor, dry character, it will give every satisfaction, and prove a permanent [illegible] of the rock garden or rockery wall. There it will give perpetual pleasure with its fine racemes of wonderfully large, drooping, deep blue bells, the little elevated above its carpet of small, glossy, prettily crenated leaves. I think it [illegible] semi-shaded place.—S. ARNOTT.

AUSTRALASIA.

NOTES ON VICTORIA.

IN VIEW of the post-war emigration intended by some of our men, the following may be of interest and service to such as are thinking of Victoria as their future home. This State, with its area of 80,000 square miles and its 1,400,000 population, is by far the most developed of the six States which together form the Commonwealth of Australia. Thus the area remaining of virgin Crown lands is not large, and, for the most part, consists of heavily timbered country, or areas but recently opened up by roads and not yet served by railway.

But in most of the districts already well settled, and served with every convenience for transport, the Closer Settlement Board has purchased large estates, and by judicious sub division has made available for selection land already in full production. This land is in blocks varying in size according to the district and capabilities of the soil, thus, close to large centres of population, where an assured market is at hand, there are 10 to 25 acre blocks suited to poultry raising or market gardening. In the country districts there are blocks of 25 to 160 acres for the growing of field crops, dairying, etc., and also larger areas for mixed farming—sheep and cattle raising, and other agricultural purposes.

The climate of the State is excellent, and facilities such as roads, railways, post offices and schools are quite up to date.

The seasons are well defined, and the temperature ranges from the night frosts of 26° experienced during June, July and August, to the 90-100° in the shade of December to March. Rainfall is fairly regular (quite regular in the cultivation half of the State), being from 10 to 15 inches in the extreme north west corner, where two million acres of Wheat show the main industry. Twenty to thirty inches is the average of the fertile, well watered Goulburn Valley and north eastern districts, where Wheat, wool, and dairying share equally, supported well by vineyards and fruit growing.

The S.W. corner is favoured with 25 to 36 inches, and here are some hundreds of square miles of wonderfully fertile country, used mainly for dairying; its price per acre, £50 to £150 is sufficient evidence of its productivity.

The S.E.—or Gippsland—quarter is the best developed, owing to its country being in the main heavily timbered; but its forests are pierced by numerous rivers and by large areas of rich river flats, and to-day Gippsland has fifty towns and villages, prosperous under a certain rainfall of 30-50 inches. The main industries are [illegible]

cutting, the growing of field crops, dairying, and stock-raising.

The centre of the State enjoys 20-35 inches of rain, and produces Wheat, wool, fruit, and dairy products. As the central district includes the three cities of Melbourne, Ballarat, and Geelong, intensive culture is also prominent.

Industries already well established, yet inviting many new members, are the breeding for pure stock or meat market of all farmyard animals; the growing of field crops for market, viz., Potatos, Onions, Carrots, Sugar Beet, Lucerne and Hay; the growing for inter-State consumption, or canning, drying, preserving for jams for export, etc., of fruits such as Apples, Pears, all stone fruits, nuts, citrus fruits, and berries of all kinds; market gardening as in England, differing only in that the use of glass and heat is necessary in the raising of early plants. I hope shortly to deal with yields, markets, expenses, and returns, of fruit and field crops.

That the settlement is well distributed is shown by the disposition of the population, which, roughly speaking, is as follows:—Melbourne, the capital city—with its suburbs—holds 600,000 people; Geelong, 45 miles S.W., Ballarat 75, and Bendigo, 120 miles N.W., each contain about 30,000. Scattered all over the State are 30 odd towns of from 3 to 10 thousand people; and there are about 250 smaller and younger townships (villages). The class of neighbour that might be expected and the prosperity that everywhere exists, can be judged by the facts that this State has sent approximately 100,000 soldiers to the war, and has subscribed well over £1,500,000 to the main war relief funds, apart from the innumerable local funds. Its latest item in this line is £155,000 to "Our Day" Fund at the end of October last. *G. Errey.*

HARDY FLOWER BORDER.

CAMPANULA AMABILIS.

AMONG border Campanulas C. amabilis is certain to occupy a good position in the future. The plant is already a favourite with those who know it. When grown in rich soil it grows about 5 feet tall, but it looks equally well when in a poorer compost and only about 2 feet in stature. It is of comparatively slender and graceful habit, and bears a multitude of large, deep blue flowers of much beauty. In some places, it must be admitted, the plant has not been long lived, but I think this must be attributable mainly to want of care by allowing it to become overgrown by other subjects, or from want of top-dressing in spring. *A.*

BULB GARDEN.

HOME-GROWN BULBS OF LILIUMS.

CULTIVATORS of the different Liliums have long recognised the fact that many species are extremely difficult to establish permanently. Imported bulbs of some species will absolutely refuse to grow in a satisfactory manner after they have had their basal roots cut off. This is particularly noticeable in the case of Lilium monadelphum (or Szovitzianum). I once had under my observation a large quantity of bulbs of this Lily imported from the Black Sea region. Though they were in splendid condition they never gave satisfaction. Some comparatively small English-grown bulbs similarly treated became thoroughly established. Lilium giganteum is a species in which the planting of large bulbs is sure to disappoint. It has been often suggested that bulbs raised from seed in this country would be the most likely to succeed in our gardens. Such bulbs have, until recently, been unobtainable from the ordinary trade sources, but latterly more attention has been paid by traders to home-grown bulbs. *W. T.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

CUCUMBERS.—A very important detail in the management of spring-sown Cucumbers is to set the plants in their fruiting quarters before they become pot-bound. As a rule, as soon as the seedlings are developing their rough leaves they may be planted, but the heap of soil should be warmed before this is done. As the main shoot approaches the trellis the laterals should be pinched at the first or second leaf, and the main stem itself stopped later to preserve an even balance of growth. The extra sap received by the side growths will favour their fruiting. By pinching other laterals at the first leaf, a well-balanced plant will soon be formed. The roots at this stage will have grown freely in the soil. With a brisk bottom-heat the temperature of the house should range from 66° to 70° at night, and 75° to 80° by day, allowing a rise of 5° to 10° with sun-heat after closing the ventilators and damping the bare spaces liberally with moisture. The plants will be greatly benefited by light top-dressings of rich, open soil each time the roots appear on the surface. Do not over-crop at this stage unless the demand for fruits is pressing, and prepare another house for a succession crop, if not already done; let the structure be thoroughly cleansed.

HERBS.—During mild weather let the herb border receive attention, or plant a fresh one if considered necessary. If it be decided to plant a new border, choose a site that is easily accessible and ground that has been thoroughly trenched and well manured. All kinds of herbs are easy to cultivate, and should be planted together as much as possible, or there will be loss of time in collecting samples. Mint is sometimes difficult to grow in dry, sandy soils, and should be planted in the coolest and dampest situation. Leaf-mould, road scrapings, burnt ash and similar materials should be used freely for lightening heavy, tenacious soils.

SEED-SOWING.—A few seeds of certain kinds of vegetables may be sown on gentle hot-beds. Lettuces, Carrots, and Turnips that have been gently forced are of superior quality to those grown out-of-doors. Early Lettuce is usually rather tough when grown entirely in the open. Good results are obtained with these three crops by growing them in cool frames covered at night with mats. Cauliflowers, both early and successional varieties for planting out on a warm border, may be forwarded by sowing in this manner. Cauliflower plants that have been wintered in cold frames should still be grown in the frames, but given abundance of air in order to keep them dwarf and hardy. Unless frost prevails, transplanting may be done during the second or third week in March. Seeds of Dwarf Gem Brussels Sprouts may be sown in the same manner for early supplies, and successional sowings of this green crop may be made at the beginning of March. Make frequent small sowings of Radish on gentle hot-beds. Sow the seeds thinly and water them freely to encourage rapid germination and quick growth. Ventilate the frame liberally as the plants increase in growth with brighter and warmer days.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

AERIDES, SACCOLABIUM, AND ANGRAECUM.—Plants of these three genera are showing signs of renewed root action, and any necessary repotting should be carried out at this stage. It is not desirable to repot the plants unless it is absolutely necessary. If repotting is decided on, first remove the old potting material from between the roots and wash the smaller particles from amongst the drainage. Aerides and the stronger-growing Angraecums are best grown in pots, while Saccolabiums and the smaller-growing Angraecums succeed best in Teak-wood baskets. Plants that have become leggy through losing a number of their lower leaves should be shortened by cutting away a portion of the stem, but retaining a sufficient number of roots. In repotting, arrange flat crocks over the bottom of the receptacles, place the stem of the plant as low down in the basket as possible, and then carefully place clean crocks between the roots to one-half the depth, filling the remaining space with clean Sphagnum-moss, mixed with pot-sherds. Fill the receptacles to their rims with the compost, arranging it in the form of a mound in the middle of the pot or basket. Cover the surface with a layer of living Sphagnum-moss. Cleanse the plants thoroughly from scale insects, which infest the stems and axils of the leaves. Water the roots copiously, and place the plants in the warmest house. Keep the Sphagnum-moss green by lightly spraying with clear water until growth is active, when water may be given liberally. Aerides Lindleyanum, A. crassifolium, A. crispum, and A. Warnerii are best grown in an airy position, in a house having an intermediate temperature.

CATTLEYA AND LAELIA.—Cattleya Trianae, C. Percivalliana, C. chocoensis, and many hybrids that flower at this season, will now be pushing their flower-spikes through the sheaths, and the plants should be afforded a little extra water at the roots, withholding moisture again as soon as the blooms are fully expanded, after which very little water will be needed until the plants again begin to grow. The roots of dormant Cattleyas and Laelias should be kept comparatively dry, until their flower-spikes develop or growth recommences. Well-matured specimens require only just enough moisture to retain their pseudo-bulbs in a plump condition. Notwithstanding that Cattleya Mendelii, C. Mossiae, and others in a resting stage are developing a number of fresh roots, they must still be watered with extra care, affording each plant a moderate quantity of moisture whenever the compost becomes quite dry. Although the present is not the usual time for repotting, any plants that have commenced to make new growths and are beginning to push fresh roots from the bases of the last pseudo-bulbs, may be repotted if necessary. The work is better done now than when the young roots have attached themselves firmly to the sides of the pots. During the winter months, Cattleyas and Laelias are very subject to the attacks of scale insects, which should be removed by sponging the leaves and rhizomes with an insecticide, taking care to dislodge the pests from around the eyes at the bases of the pseudo-bulbs. The creatures secrete themselves underneath the outer skin, which should be opened carefully and the pests removed by the aid of a small brush. If scale is allowed to remain unchecked, it will infest the young growths as they develop. Seedlings of these plants should be kept growing without a check until they have reached the flowering stage. If possible they should be afforded a warmer temperature than the parent plants. Greater success is obtained when a house is devoted entirely to the raising and growing of seedlings. A temperature of from 60° to 75° and a moist atmosphere are suitable conditions. Shift the plants into larger pots as they require increased room, and never allow them to become pot-bound. Employ as a rooting medium equal proportions of A1 fibre, Osmunda-fibre, and Sphagnum-moss; cut the materials rather short, and add some crushed crocks to keep the mixture porous. Vaporise the house frequently to keep down thrips. It is at this period of the year that the small yellow thrip insects multiply so fast that if immediate means are not taken to destroy them they will cause great damage to the plants. From this time onwards it will be good practice to vaporise each house once every fortnight, and on the alternate weeks the plants should be lightly sprayed overhead with some safe but effectual insecticide. It is best to do this just before sunset, as this minimises the danger of the foliage being scorched by the sun's rays. Before commencing vaporising or spraying, very little damping down should be done, but a moderately high temperature should be maintained, so as to induce the insects to emerge from the places of their concealment.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

PROTECTING THE BLOSSOMS OF WALL TREES.—Last year, in consequence of the phenomenally late season, I decided to risk any possible danger of injury from frost, and our trees escaped. This year it will not be expedient to take such a risk, as the flower-buds are already swelling much too fast. My plan is to protect the blossom with half-inch fish-netting made on the square mesh, which causes it to hang true; this I find gives ample protection. When short of this netting I have used two thicknesses of one-inch netting, also made on the square mesh; this I found to answer well. This netting is 9 feet wide, but does not touch the ground by about 3 feet. It is fixed at the top of the wall to a running wire, and light Bamboo rods are arranged slantwise from the wall and secured against any possible movement, the netting being tied to the rods. This device affords ample protection to keep the blossoms dry, which is most essential. A few hives of bees are near to the wall, and the bees do not mind the netting in the least.

WALL COPINGS OF GLASS.—Wall copings afford the best means of protecting fruit blossom from spring frosts. To fix such copings at the present time is not, perhaps, advisable, but they repay the outlay. Where such copings are provided 1-inch mesh netting is quite sufficient, and it may be allowed to hang nearly perpendicularly with sufficient stakes to prevent the netting beating in the slightest degree against the trees. I am not in favour of using thicker material than these netings unless the garden is in a very cold district. Heavy screens should be hung with rings from the top of the wall in order to be easily movable in bright weather.

PRUNING NEWLY PLANTED TREES.—In the autumn of 1916 I planted standard trees of Damsons. As I do not favour severe top pruning when planting, the shoots were only shortened about one-third their length. Short, stocky shoots developed last season, and these are now closely studded with fruit-buds. Fruit trees planted now should be pruned more severely, as the roots would be inactive for some time. In the case of late-planted Apples and Pears I would also remove all the flower-buds, apply a mulch to the roots, and water the trees immediately they were planted. Standard trees should be supported to stakes directly they are planted, while bushes and pyramids should be made secure against spring gales.

THE STORING OF FRUIT. Some useful notes on this subject have been published in recent issues of the *Gardeners' Chronicle*, including those from the Hon. Vicary Gibbs and Mr. Edwin Beckett. It must be remembered that my advice to spread the fruits thinly on the shelves was given at a time when many of the latter were empty. When our Apples were first placed in store some were arranged at least six layers deep, but as soon as space was available they were given more room, and doubtless Mr. Beckett has done the same some weeks ago.

FRUITS UNDER GLASS.

By W. J. GUISE Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

YOUNG VINES.—There is still time to propagate Vines from eyes, and prunings that were heeled in on a border outside for this purpose should receive attention. No advantage is gained by delaying the work after February. Eyes that were inserted in small pots as advised last month will soon be ready for shifting into 6-inch pots. Use a compost consisting of loam, bone meal, and mortar rubble, and plunge the cutting pots into a bottom heat of 70° to 80° and keep the atmosphere moist. Light syringings will keep the buds damp enough for the present. Guard against a sudden lowering of the temperature, which would give a check that would seriously injure the young plants. Cut back vines should be shaken out, as soon as the buds have started, and shifted into 10-inch pots. The soil for these vines should consist of a mixture of rich, firm, fibrous turf, ½-inch bones, and lime rubble. A similar temperature and treatment as previously advised will suit these also, but very little water must be given until the roots have taken full possession of the soil. Vines planted in borders last year should be allowed to develop slowly. Aim at building up a sturdy, short-jointed rod, without unduly forcing the plants.

POT VINES.—The grower must use his discretion when thinning the bunches on pot vines. Some of the bunches may require heavy thinning, others very little; at the same time a properly thinned bunch will be free from small or stoneless berries, and still retain sufficient Grapes to form a perfect bunch. Overcropping pot vines usually ends in failure, so far as size of berry and colour go, which are the most essential points in Grape culture. Six, or, at the outside, eight, bunches, according to the vigour of the rod, are quite enough for the vine to carry. Lateral growths should be pinched and tied out to secure an even balance of foliage over the trellis, pinching the subordinals to one leaf. Suitable top-dressings of rich materials should be applied occasionally in small quantities and well watered with chilled water. Diluted liquid manure used warm is beneficial, but if given in strong doses the young roots will collapse and the foliage flag during bright weather. Discontinue direct syringing, but keep the walls and bare spaces moist. A temperature of 65° at night and 75° by day, with air according to the weather, will be suitable conditions. A few degrees higher may be allowed with sun heat when the house is closed.

SUCCESSIONAL VINERIES. The same management as advised for the early houses in a previous calendar will apply to successional vineries, except that the temperature should be a little higher as the season advances. When the buds are swelling a temperature of 60° at night and 70° by day, with a minimum temperature of 65° as the flowering period will be suitable. Take advantage of sunny days to let the temperature rise to 65° or 70° when the houses are closed. By these means a great saving of fuel will result.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to LADY WANTAGE, Lockinge Park, Berkshire.

PROPAGATING EDGING PLANTS. It is necessary to propagate fresh batches of plants used as edgings to plant-stages about twice a year, as old specimens when overgrown are unsightly. Such plants as Panicum variegatum, Pilea muscosa, and Selaginella are easily increased from cuttings, which, if rooted and grown in a moist, warm atmosphere, make useful plants in a few weeks. The cuttings may be dibbled into 3-inch pots filled with a sandy compost. Well water the cuttings and place them in a propagating case to root. Isolepis gracilis may be increased by division of the roots. Place the divided portions in 3-inch pots and arrange the pots closely together in the plant stove until they have made suitable growth.

BEGONIA. Tuberous Begonias may be raised from seeds sown during the next two or three weeks in pans. Let the seed pans be thoroughly washed and place in them plenty of drainage material. The compost should consist of a mixture of loam, leaf mould, and sand which has been passed through a fine sieve. Well water the soil before sowing the seed. Care is necessary in handling the seed, or much of it will be lost. It is a good plan in the case of all small seeds to mix it with a little very fine sand to ensure it being evenly distributed. When sown, lightly cover the seed with sand which has been passed through a hair sieve. Cover the pans with a sheet of glass, and on the glass place a sheet of brown paper until the seeds have germinated. Place the pans on a shelf in a moist, warm house. The old tubers which have been resting may be placed in boxes of clean, sifted leaf mould and the boxes stood near the roof glass in a house having an intermediate temperature. If necessary the stock may be increased by dividing some of the largest tubers. When sufficient growth has been made the plants may be potted singly in receptacles of suitable sizes and grown on gently in a moist, warm atmosphere. When the plants have filled their pots with roots they may then be given cooler treatment.

CLIVIA (MANTOPHYLLUM).—Plants of Clivia are developing their flower-spikes, and need copious supplies of water and stimulants, or the flowers will be lacking in colour. After flowering any repotting necessary may be done. This plant is easily increased by division of the roots, which can be done while the work of repotting is in progress. Provide a rich rooting medium, as the Clivia is a gross feeding plant. If the plants have been repotted in recent years they need not be disturbed now, for specimens grow and flower satisfactorily in the same pot for several years provided they are afforded plenty of stimulants during the growing season.

THE FORCING HOUSE. There should be no difficulty in providing a good supply of flowering plants, as the various kinds of forcing subjects require very little fire heat to bring them into flower. Before using flowering plants in the dwelling grow them for a short period in a cool house. It may be necessary to retard some of the later batches of Narcissi and Tulips by placing them in a cool house or frame on the north side of a wall. Lilacs and species of Prunus and Pyrus may still be lifted from the open ground and placed in the forcing house as required.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

CALCEOLARIA.—If pyramid or standard plants of Calceolaria amplexicaulis are required, transfer the plants to 7 or 8 inch pots, and grow them in a temperature of 55° to 65°. Exercise care that they suffer no check to growth from lack of moisture at the roots. Once started into free growth, the plants make remarkable growth.

HUMEA ELEGANS.—Plants of Humea elegans that have been kept on the dry side through the winter will from now onward require more moisture at the roots. Do not be tempted to raise the temperature by the use of fire heat.

CAMOMILE.—I grew a quantity of this medicinal herb last year, and was not a little surprised at the long-continued bloom produced and the fairly good effect the plants gave in the mass. The plant is easy to cultivate, and rooted pieces detached from old plants at the present time and set 9 inches apart will do excellently well in beds.

TRANSPLANTING SHRUBS.—This note is rather a caveat than any advice. It is usual to transplant shrubs about this date, but, of all seasons, probably there is no worse than the present for the well-doing of the shrubs themselves. The best time is autumn, on the whole. But when circumstances do not permit of transplanting then, the next best time is when the buds are on the point of bursting. The work needs to be carried out without delay in order that the roots are not dried, and a soaking of water must follow immediately on planting, a mulch, if it be even of dry soil, following, when nothing more will be needed. I have moved a great variety of shrubs and trees at the point of growth indicated, including tall Conifers, Hollies, deciduous and evergreen Oaks, dwarf shrubs of various kinds, and Apples, and have never had a failure. So, if possible, refrain from transplanting, as I am doing with a lot of large shrubs, till growth is on the point of breaking. These include Daphniphyllum, Japanese Oak, Cornus Mas, tall and old Yews, and more common subjects.

WILLOWS.—The cutting over of dwarf and the pruning of standard Willows grown for the colour of their bark, Dogwoods and others of a like nature should soon be seen to. When cut year after year a little in advance of the portion cut the previous year, the shoots gradually become weaker and when this is observed by cutting below these scraggy portions and the soil properly dressed with manure, the original vigour will be renewed. Willows may always be cut down to the ground level with advantage.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications, and save as much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENT FOR THE ENSUING WEEK.

WEDNESDAY, FEBRUARY 27—
Elgin Bot. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.1.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London: *Thursday*, February 21, 10 a.m.: Bar. 30.1; temp. 45.0°. Weather: Bright sunshine.

A New Parasite of Potatos.

The pathogenic troubles of the Potato are well-nigh endless; they come not as single spies, but in battalions. The latest addition to the parasites of the Potato is Tylenchus penetrans, a nematode worm allied to the well known root and stem parasite, which causes trouble in Cucumbers and many other plants. An attack by this parasite may be recognised by the presence of numbers of minute pimples on the surface of the Potato tuber. Each pimple is perforated by a minute opening, through which the parasites escape from the Potato, and no doubt pass through the soil into other tubers. If the infection is severe the number of blisters or pimples may become considerable; the separate swellings run together, and the surface becomes shrunken owing to the collapse of the tissues.

Mr. N. A. Cobb, of the Bureau of Plant Industry, U.S. Department of Agriculture, who has published a description* of this parasite, states that Tylenchus penetrans also attacks the roots of Violets and causes serious damage to the plants. In the case of the Potato the damage done by this nematode is apt also to be serious. An attack leads to reduced yield and small and unsightly tubers. The reduction of yield is to be ascribed to the fact that the parasite gains access not only to the tubers, but also to the root-system. That the pest is likely to prove troublesome may be judged from the fact that it has already been found in plants growing under such different climatic conditions as those which occur in Florida, Georgia, North Carolina, New York, and Michigan; and we have already had so many North American plant parasites that we shall do well to be on the look-out for the advent of this latest addition to their number.

Tylenchus penetrans falls among the specialist parasites; that is, it only affects (so far as is known) a few plants, and in this respect differs greatly from its formidable ally Heterodera radicicola, which is known to infest no fewer than 500 different species of plant. Indeed, it is not improbable that this latter eelworm is of all pests that which does the most damage to garden crops. Therein lies an additional reason why Potato growers should keep a sharp look-out for the appearance of the minute pustule which is a sign of the presence of the newly described Potato eelworm, and should above all avoid planting any seed tubers the aspect of which is open to suspicion. Microscopic examination of suspected tubers is a ready means of determining whether the eelworm is or is not present; for the parasite once seen under the microscope is easily recognised, and its size—about 1-25th of an inch—makes it visible even with a very low magnification. Although care in the selection of seed is the best means of preventing the spread of this pest—as it is of so many others—another means consists in treating the tubers with a weak solution of corrosive sublimate, the poison used successfully for the treatment of Potato scab.

Mr. Cobb's account of this pest contains excellent illustrations of Tylenchus penetrans, and a full description of the characters which distinguish it from the other parasitic eelworms.

* *Journal of Agric. Research*, Washington D.C. Oct. 3, 1917.

HORTICULTURAL CLUB.—The annual general meeting of the members of the Horticultural Club will take place on the 26th inst., at 2, Whitehall Court, Whitehall, S.W., at 5 p.m. The president, SIR FRANK CRISP, Bart., will preside. On this occasion the house dinner, which usually follows the business meeting, will not take place. Whitehall Court is situated immediately at the back of the War Office, and the Club Room is on the second floor.

ALLOTMENTS IN GLASGOW.—A memorandum issued by Mr. JAMES WHITTON, the Superintendent of Parks at Glasgow, on the subject of the allotments under his direction, shows that there was a keen demand for allotments in the Glasgow district in 1916 and 1917. The number of plots provided amounts to about four thousand, the average size being from 200 to 250 square yards. The intention at first was to let plots of varying sizes, *i.e.*, 200, 250, and 300 square yards; but it was found that in the great majority of cases 200 yards was all that one holder could cultivate well, and all plots now let are of this size. The results during 1917 were very satisfactory, and the crop of Potatos alone on all the plots combined amounted to about 1,300 tons. The Parks Department has given a great deal of assistance to plot-holders in such matters as the erection of tool sheds, fencing, and in the provision of a certain amount of skilled advice.

GOVERNMENT SEED-TESTING STATION.—Over 4,000 samples of seeds have been received for testing at the Government Seed Testing Station, under the Food Production Department, at 72 Victoria Street, since the station was opened in November.

THE KILLING OF MIGRATORY BIRDS.—The Board of Agriculture has made an Order extending to March 31, 1918, the time for killing in England and Wales a number of migratory wild birds, including the curlew, the knot, the whimbrel, the golden plover, the red shank, the godwit, the snipe, the woodcock, the teal, the widgeon, the mallard, the shoveller, the pochard, the white-fronted goose, the pink-footed goose, and the grey leg goose. By the same Order the time for the lawful sale, exposure, or offer for sale, or possession of any of these birds is extended to April 15, 1918.

HONOUR FOR M. D. BOIS.—The French Academy of Science has bestowed on Monsieur D. BOIS, Editor of the *Revue Horticole*, the Parville Prize of a thousand francs. This distinction is given as a reward for services rendered to the cause of science. The prize marks in a tangible manner the valuable work done by M. BOIS for many years in introducing and popularising in his own country the vegetable productions of the colonies.

FLOWERS IN SEASON.—Mr. JAMES A. PAICE sends from Aldenham Vicarage Gardens spikes of Iris stylosa, which he states is flowering magnificently in the Vicarage Gardens this season.

PRICES OF COPPER SULPHATE FOR POTATO SPRAYING.—Maximum prices have been fixed for sulphate of copper for agricultural purposes. Potato growers are urged by the Food Production Department to place orders for this material with their usual merchants or dealers without delay, and to take delivery as soon as possible. The prices are based on a sliding scale, and deliveries early in the season will be made at a lower price. The price for sales of quantities of not less than 1 ton by makers f.o.r. at works is £48 per ton in January-February delivery; £50 per ton March-April delivery; £52 per ton May-August delivery. The prices for sales by merchants, dealers, chemists, and others, ex store, shop, or warehouse, are as follows:—

Quantity included in sale.	Date for delivery. Jan.-Feb.	Mar.-April.	May-Aug. inclusive.
2 cwts. and over	54s.	55s.	56s. per cwt.
56 lbs. but less than 2 cwts.	56s.	57s.	58s. ,,
28 lbs. ,, ,, 56 lbs.	58d.	59s.	60s. ,,
8 lbs. ,, ,, 28 lbs.	6d.	7d.	7d. per lb.
4 lbs. ,, ,, 8 lbs.	7d.	7½d.	8d. ,,
1 lb. ,, ,, 4 lbs.	8d.	8½d.	9d. ,,

THE ONION MAGGOT.—From experiments carried out by Mr. A. GIBSON at Ottawa* it appears that the damage done by the Onion maggot (Hylemyia antiqua) may be in large measure prevented by spraying the plants with a mixture of sodium arsenite (½oz.), molasses 1 pint, and water 1 gallon. The sodium arsenite is dissolved in the water, which must be boiling, the molasses are then added, and when cool the mixture is ready for use. It may be applied by means of a watering-can, and owes its effect to its attracting and poisoning the adult flies.

LOCAL SOCIETIES.—The annual meeting of the Norfolk and Norwich Horticultural Society was held on the 2nd inst.: the president, Mr. J. A. CHRISTIE, was in the chair. The financial statement showed that there was a credit balance of more than £93. Mr. J. E. T. POLLARD was elected hon. secretary, and the other officers were re-elected.

—— The Merton Horticultural Society's annual meeting took place on the 29th ult., when Mr. R. PETERSON, the president, occupied the chair. The officers were re-elected, and three new members added to the committee. The Society has a credit balance of nearly £12. It was decided to hold a show on August Bank Holiday.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

EFFECT OF SUNLIGHT ON GROWTH.—In your issue of December 8, 1917, p. 251, you referred to a collection of "sports" exhibited by me at the Royal Society, illustrating, amongst others, leaf-division, proliferation, spur-peloria, and fasciation, which had been produced at will in sunlight by selective screening. It may interest some of your readers to know that a specimen of Tropæolum tuberosum, showing pre-arranged leaf-division, is now deposited in the Botany section of the National History Museum, South Kensington. The experiment was repeated during last summer at Dr. Rendle's request, and was quite successful, the leaves either entire or with different numbers of lobes, being grown in sunlight where desired, up a stem of exciting 8 feet in height and upon lateral shoots. *H. E. Durham (Col.), Home Close, Harrogate, Horticulturist.*

THE STORING OF APPLES.—The remarks of Mr. Hudson and of Mr. Beckett bear out to a contradictory, as Mr. Hudson was apparently writing of choice dessert Apples and Pears needing ripeness, whilst Mr. Beckett was dealing with the storing of late Apples. I have packed Apples in boxes 4 feet deep in October and taken them out in February as fresh and sound as when stored. I prefer boxes that will hold about a bushel, but they are not always at hand, and when there are hundreds of bushels from the orchard they must be stored as best one can. Doubtless the object of having lattice shelves in fruit rooms is to see each fruit at a glance and determine readily when it is ripe for use. A young man I have put Apples and Pears in single layers on lattice shelves and in shallow drawers, with the result that the fruits shrivelled by Christmas. Like Mr. Beckett, the Apples in the grass set me thinking. I dissent from the statement of *A. C.* p. 151 that fruit gathered wet is better than when dry. That may be the case if the fruit is quite sound and free from disease, and of the harder and later kinds such as Norfolk Beauty, Lemon Pippin, French Crab, and Northern Greening. He also states that fruit should be gathered before it is ripe; this requires to be qualified. "Fit to gather" and "ripe" are two quite distinct terms. Ever, Ribston Pippins and King of the Pippins are gathered before ripe, not to mention all the fruit that rot from November till May. But the fruits are "fit to gather" when they part easily from the tree. There is one point to remember—all fruit is best in its season; when that season is past it is of less value, even if it keeps sound. *Jap.*

GROWTH OF SNOWDROPS.—The illustrations of Snowdrops in fig. 14, *on* p. 33, are interesting so far as they go, but would have been much more instructive had exact details of temperature, rainfall, and sunshine been given for the district in which they are growing during the month of December, or at least the last fortnight thereof, in each case; also the date in each year when the leaves first appeared through the surface. Perhaps the contributor of the photograph can supply these data. If not, may I suggest that in succeeding years the clump be kept under careful observation, and these details recorded. So far as one can judge with rough records, temperature alone is of far more importance than rainfall or sunshine at that period of the year. *C. Nicholson, Chingford.*

APPLES RIVAL AND BARNACK BEAUTY.—In reply to *Southern Grower's* inquiry, on p. 51, as to the merits of Apples Rival and Barnack Beauty, I may state that I have grown them both for upwards of ten years and they have never failed to give good average crops. Rival is a good grower, and the fruit has a very pleasing appearance, which, for market purposes, is in its favour. The fruits keep well into December and are usually very firm, a point of importance for varieties to travel well when picked for market. Barnack Beauty I consider a most useful late Apple, and the flavour is quite up to the average for Apples after the turn of the year. In appearance the fruit cannot compare with Rival, but on the sunny side they develop a bright crimson colour. The fruits are of good average size, and remain firm well into February. My trees are all bush or trained specimens, and I do not know how they would succeed as standards. For a shore is rather a heavy soil, and a clayey subsoil. *R. Stephenson, Brickhill Gardens, Hertford.*

RELIEVING LABOUR.—On p. 4 Mr. Brockbank refers to using flower-beds. Surely these must be very few at this time; they should be filled with roots of Beans, Carrots, or other vegetables that are suitable; last year every odd corner in my garden where there was a blank space, that is beds, rockery, and odd corners, was sown with dwarf Beans, and from these we harvested several pounds of Beans. A large [illegible] in the district filled all his flower borders with Beets and Carrots. I would say, do not *cultivate* what is cultivated, and rather grow crops that need little attention to save labour. *H. E. D.*

YEW POISONING (see p. 70: *Pur. Ed.*) we find the question of Yew poisoning of animals fully dealt with on p. 63 of the R.H.S. *Gardeners' Diary* for 1918. I venture to suggest that in the case of the particular field to which he refers in which are Yews that have never proved fatal to animals, the ground is in good fertility, the stock well fed, and therefore the animals do not eat the Yew greedily. *Weather spoon, Mount Ballan, Chepstow.*

ON INCREASED FOOD PRODUCTION

LECTURE ON POTATO GROWING.

[illegible] the auspices of the Royal Horticultural Society, a public lecture on Potato growing was delivered in the Mansion House, London, on the 15th inst., by Mr. W. Cuthbertson, F.L.S. The Right Hon. Lord Mayor presided, accompanied by the Lady Mayoress, and he was supported by Mr. A. Lansbourne, Sir Jeremiah Colman, Bart., Mr. Veitch, Rev. W. Wilks, Mr. F. [illegible], the Board of Agriculture, the Fruiterers' Company, and a number of other distinguished people interested in cultivation. The large hall of the Mansion House was crowded to its utmost capacity, and many people were unable to find seats.

Mr. Cuthbertson commenced by saying that in 1916 17,200,000 new allotments were created in this country. These allotments occupied more than 13,000 acres of land, and more than a million people must have been directly interested in them. He advised that the Potato crop should be the chief consideration of allotments, and proceeded to give hints on [illegible] cultivation as follows: "I should like to

FIG. 35.—ODONTOGLOSSUM MEMORIA F. M. OLIVER: A SPIKE OF FLOWERS BRIGHT CLARET-RED WITH WHITE MARKINGS AND FRILLED LIP. (See p. [illegible])

gest that you do not require to buy all the seed Potatos you require every year. If you are growing from Scotch or Irish seed, dig up a number of roots in the summer or early autumn before they are quite ripe, allow the tubers to lie on the ground for a few days to become green, and then put them away in boxes in a cool, shady place to be kept for seed next year. This is the method followed by many of the largest and most successful growers. 'Once-grown seed,' that is, tubers which have been grown from Scotch or Irish seed, will generally, if properly handled, give as good a crop the second year as the first, but after that the virtue of their origin seems to have gone. Fill one-half or three-quarters of your Potato land with this once-grown seed, and buy every year from Scotland or Ireland as much fresh seed as will plant the other half or quarter of your land, and then save as many tubers from it as will plant a half or three-quarters of the ground the following year.

"You may ask why Scotch or Irish seed is best. The real reason, I think, is that it is less ripened, less matured, and, coming from a colder to a warmer climate, it brings with it the vigour of the colder climate, and this tells largely on the cropping results for two years.

planting to allow the cut surfaces to dry. Even in February it is well worth while to hox seed; in six weeks' time sets will sprout satisfactorily. Any box 3 inches deep will do to hold them.

"Among the early varieties tried at Wisley by the R.H.S., Midlothian Early and Duke of York are considered to be the best first earlies. These two Potatos are nearly identical. May Queen is another good early sort, but we always find difficulty in keeping it north of the Tweed. If you lift the crop of Midlothian Early or Duke of York when the tubers are ripe and store them you will find they will be quite good for eating until October. Other early varieties (though not quite so early as Midlothian) which are commended by the R.H.S. after cropping and cooking tests, are Sharpe's Express, Sir John Llewelyn, Stirling Castle, and Witch Hill.

"What are called mid-season or second-early varieties are a big class, but do not grow very many of them; perhaps about as many as you do of the earlies. The two mid-season varieties I should advise are British Queen and Great Scot. The former is kidney-shaped, the latter round.

"The late or main crop section is by far the most important of all. For many years Up-to-Date has stood at the head of it. Dalhousie

son in the important trials conducted yearly by the Board of Agriculture at Ormskirk.

"All land is the better for an occasional dressing of lime. If yours has not had one recently you might give it a top-dressing before you begin to work it down for planting—say 4 ounces of the finest powdered lime to the square yard. Lime unlocks, and makes available, the plant foods in the soil. It prevents a soil from becoming too acid—too sour, to use a common expression.

"When planting on a small scale, set a line across the patch, and with a spade take out a trench or opening in the shape of a V, but with one side straight—3 to 4 inches deep. Along the bottom of this sprinkle a little artificial manure; 2 ounces to the square yard will be enough. If you have any old potting soil or wood ashes, or leaf-mould, make the trench a little deeper and spread these materials along the bottom. Lay the sets in the trench carefully, sprouts upwards, giving the tuber a gentle press into the soil. Push back the soil taken out and restore the level surface, thus leaving the tubers covered with 2 to 3 inches of soil. Watch carefully for the appearance of growth above ground, and whenever you observe it, draw soil with a hoe from either side on to the top of

FIG. 36.—SPROUTED SET SUITABLE FOR DIVIDING.

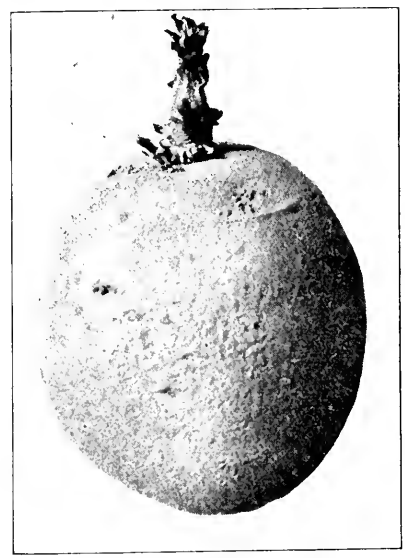

FIG. 37.—SEED TUBER WITH A SINGLE SPROUT.

seed Potatos should be sown in boxes. Well-sprouted seed will increase the crop by 20 to 25 per cent. The big Ayrshire and Lincolnshire growers have buildings specially erected for the purpose and made to hold thousands of large boxes. The object is to get strong, stubby, dark green sprouts on the tubers at planting time. By watching the sprouts carefully in the early stages, you can form an opinion whether your seedsman has supplied you with a pure stock or not. The sprouts of some varieties are black, of some they are purple, of some pink, some are green, and some nearly white. If your box of tubers is producing sprouts all of the same colour you may be satisfied that you have secured a fairly pure stock. If course it is possible that two varieties having the same coloured sprouts might be mixed and so not able to be detected.

"Ideal seed tubers are between two and three ounces in weight, but to get all seed Potatos that size is impossible. I should advise you to plant sound tubers anywhere between 1½ and 4 ounces, and tubers larger than 4 ounces you should cut into two or three sets, according to the size of the tuber and according to the number of eyes (see fig. 36). Two strong eyes, at least, should be left on every set. Cut the tubers into sets a few days before

Seedling, The Factor, Duchess of Cornwall and Dobbie's Prolific are all closely akin to Up-to-Date. Varieties of the Up-to-Date class did remarkably well in 1917, but for some years previously they had not been doing so well. They want extra good cultivation, and they must be sprayed. The wise man, I think, would plant half of his late variety space with an 'Up-to-Date' type and the other half with Arran Chief or King Edward or Golden Wonder.

"There are many new varieties on the market. The most remarkable novelties I have seen are Majestic, a distinct, heavy cropping, white kidney, from the raiser of Up-to-Date—Mr. Findlay, of Markinch—and Kerr's Pink, a round variety, flushed with pink, a good keeper and cooker.

"Both Majestic and Kerr's Pink are resistant to wart disease. There is no remedy for those varieties which are susceptible to the wart disease, but fortunately a number of varieties are immune. These only should be planted in infected gardens. The best available immune varieties are: Second early, King George and Great Scot; main crop, Golden Wonder, The Provost, Kerr's Pink, The Lochar, Tinwald Perfection, and The Ally. The three last have each gained gold medals presented by Lord Derby for the best immune variety of the sea-

it. If the sprouts on your tubers are long you will require to ridge up the soil over them at once. If the growths push through again while there is still a danger of their being injured by frost, do not be afraid to draw up more soil and cover them again. When danger of frost is over, draw up more soil—plenty of it this time—right up against the stems, bringing the soil from the middle of the row. All that it is necessary to do after that is to keep the plot free from weeds. Never work the land, or even walk between the drills, when the ground is wet, particularly in the case of heavy soils. If you have not time to plant as I have described, after setting the line take out slits with a spade at the proper distance and get someone to put in the sets, after which allow the soil to fall back on them; or if working single-handed use a trowel.

"In deciding the distance at which to plant, there are several things to consider, such as strength of soil, strength of haulm, whether early, second early, or late varieties. On moderate land plant early varieties in rows 24 inches apart, placing the sets 12 inches apart in the row; second earlies 28 by 14; and late varieties 30 by 15. For confined gardens—I mean small plots surrounded by high walls or high hedges—early varieties should mostly be grown, and

they should be given plenty of room In this connection I advise keeping the new variety Majestic in view. The haulm is not too strong and the plant gives plenty of tubers. On an open allotment the right proportion of the different classes to plant is one part early, one part second early, and four parts late. One often reads the advice that sets should be disbudded—that is, that before planting, the growths from all the eyes, except one or two, should be rubbed off. I never myself pay any attention to these recommendations, nor do any of the big growers. Even in our trails, where we often get an average yield of 4 pounds a root, we do not disbud.

"If you have planted good, sound, healthy tubers you are not likely to have much trouble, except with ordinary 'blight' (Phytophthora infestans). If your seed has not been of the best you may have 'leaf-curl,' for which there is no known cure. You may also have 'blackleg.' The latter is observed by the wilting and slight yellowing of the foliage. If the stem is pulled the base is found to be black. If the stem is cut across above where it is black, little brown spots will be observable at the corners—a sure indication of 'blackleg.' It is not often a large percentage of plants is attacked, but those that are diseased should be dug up and burned—tops and tubers too if any have formed, as the 'blackleg' disease is carried in the tuber.

"Ordinary Potato disease, or 'blight,' cannot be cured, but it can be prevented, and the only preventive I know of is spraying with Bordeaux or Burgundy mixture while the plants are still healthy. The Government prescription is 4 lbs. sulphate of copper, 5 lbs. washing soda, 40 gallons water; this is called Burgundy mixture. The materials are dissolved separately and then mixed, adding the soda to the copper solution. The specific should be applied with a fine sprayer, the object being to coat the entire surface of the plant with the spray, which will dry on the leaves and stems and so prevent the spores of the fungus attacking them. Do not be content with spraying once; give two or even three doses at intervals. Green fly may attack the haulm. The Bordeaux or Burgundy mixture, if applied in time, will help to obviate this pest too. Bordeaux mixture is made by using lime instead of soda, and the formula is usually 5 lbs. copper sulphate 5 lbs. lime 50 gallons water.

Lord Lambourne rose, on behalf of the Royal Horticultural Society, to propose a vote of thanks to the Lord Mayor for presiding, and to Mr. Cuthbertson for his interesting lecture. He had noticed that on every occasion in which the welfare of the citizens of London or the people of this country were concerned, the Mayor was always ready to render the utmost assistance, and he felt sure he spoke in the name of all present in expressing deep gratitude to him and to the Lady Mayoress not only for presiding over the meeting, but for lending the Mansion House for the occasion. Lord Lambourne referred to the work done by the R.H.S. in stimulating food production, and mentioned that the Society had been the first to call attention to the danger of a scarcity of food. The vote of thanks was carried with acclamation. Mr. Cuthbertson briefly acknowledged it, and the Lord Mayor, in reply, said he immensely appreciated the kind way in which Lord Lambourne had spoken of him, and the honour done him by the members of the audience, who had come in such large numbers to hear the lecture. He was only sorry that his own gardener was unable to be present, but he should send him a copy of the pamphlet in which the lecture had been printed.

HARICOT BEANS

A SLIGHT error crept into my article on Haricot Beans (p. 59), which states that a pint of seed was sown, whereas it should have read half pint of Princess of Wales Bean was sown. *G. H. H. W.*

A POTATO COMPETITION

A SUCCESSFUL Potato competition was held in Glencairn, Dumfriesshire, last year, and at a recent meeting it was agreed to hold a similar competition in the ensuing season. Mr. Macara, merchant, Moniaive, has offered the prize money, and Mr. T. Oliver, who is on active service, will contribute the seed tubers, as he did last year.

CROPS AND STOCK ON THE HOME FARM.

INCREASING THE AREA FOR CORN CROPS.

THE ploughing of grass, Saintoin, and leys for cereal crops is a matter of extreme urgency, and should engage the serious attention of farmers, large and small. Many such fields would be much more profitable under the plough. Many pastures have not been sown with seed of suitably selected permanent grasses, but are what is locally known as having "fallen down" to grass from a worn-out Sainfoin or Clover ley, and all too often the turf is composed largely with Couch and other obnoxious grasses and weeds. They are dressed occasionally with manure, and receive surface attention, consequently a little improvement is manifest, but a full crop of hay and grass is not forthcoming from such fields.

In this county all Sainfoins over five years old, and all leys, are to be ploughed and sown with cereals before March 31. In some districts Sainfoin will produce a full crop of hay for eight years, provided the ground was suitably prepared for sowing the seed. The order to plough in such circumstances is a trifle hard on some farmers, but such grass land is in the minority, and on the whole it is a wise order, and will increase the corn acreage considerably.

In the same way the ploughing of all leys—whether of Cover, Italian Rye Grass, or other annual grasses, that gave a crop of hay last season, will result in a considerable increase of the corn crops also.

Those who are, or are about to be, similarly engaged, and intend to sow Oats, should plough the heavier soils first, as more time is required to bring heavy land into a working condition for sowing than in the case of light soils, such, for example, as over the chalk. Light soil should be ploughed at the end of February or early in March, and sown forthwith. The subsequent crop will better escape injury from wireworms, as these pests will be occupied among the roots of the turf. In the meantime, by the aid of tertil sets, the Oat plant will grow rapidly, and once the second pair of leaves is formed the plant is practically safe from attack. In the case of turf, or ley ground carefully skim the surface to ensure the grass being buried when ploughing 5 inches deep. Some ploughmen do not turn the furrows over, but set them up edgewise, thus enabling the grass to grow and at the same time forming a deep opening in which the seed drops, and too often fails to germinate. Use a heavy pressure behind the plough in the furrows to ensure a firm seed bed.

Sainfoin is often densely infested with Couch grass, and some think it is better to summer fallow such ground to destroy the Couch and sow with Wheat in the autumn. If an Oat crop is grown this year much of the Couch grass will be destroyed when ploughing after harvest, and the Couch is more easily brought to the surface collected and burned. The land will then be clean for a crop of roots the following year. In this way a crop of Oats will be obtained this year amounting to at least ten sacks per acre. Green Couch is much more difficult to remove from the soil than that partly decayed. The ground should be dressed with fertilisers at the time of sowing the Oats, and the manures should be obtained at once. Four cwt. of agricultural salt, 3 cwt. of superphosphate (30 per cent. strength), and 1 cwt. of sulphate of ammonia per acre should give good results.

MANGOLDS IN CLAMPS.

As a rule the Mangolds are keeping well this season, but the roots will soon commence to sprout, which, if allowed to continue, would exhaust much of the nutriment in them. The admission of air to the roots by the removal of the soil covering will give a check to growth. Some few of the roots that were subjected to frost when lying in heaps in the fields, or that were handled during frosty weather and bruised, and decaying, and should be removed. This goes to show that a slight frost may injure the roots if they are disturbed in a frozen condition. It is better to allow them to remain undisturbed until the frost has thawed. The sound roots may be fed to sheep and pigs. *E. Molyneux, Swainmore Park Farm, Bishop's Waltham, Hampshire.*

SOCIETIES.

ROYAL HORTICULTURAL.
Scientific Committee.

FEBRUARY 12.—*Present:* Mr E. A. Bowles (in the chair), Dr Rendle, Messrs. Worsdell, Hales, Allard, Baker, Fraser, Holmes, and Chittenden (hon. sec.).

Diseased Damson-stone.—Mr. Bowles showed a stone of a Damson having four instead of two edges, which Mr. Worsdell took for further examination.

Fungus on Gardenia Roots.—Mr. Fraser showed specimens of Gardenia roots with galls upon them produced by the root-knot eelworm, Heterodera radicicola.

Food Value of Fruits.—A discussion took place on the relative food values of common fruits. The Grape has a very high food value, and the Apple also stands very high in this respect.

SCOTTISH HORTICULTURAL.

FEBRUARY 5. The first ordinary monthly meeting of this Association was held on the 5th inst. Mr. King, senior Councillor, occupied the chair, and introduced the new president, Mr Robert Fife, who delivered his inaugural address, taking as his subject "Food Production in War Time." Mr. Fife referred to the acuteness of the present shortage of food, and emphasised the urgent need of more intensive cultivation in order to maintain our supplies, not only on the farm, but by means of allotments and the employment of all available ground in private gardens. With regard to the subject of manuring, he laid great stress on the fact that there was a vast amount of loss of fertilising ingredients in our present system of sewage disposal.

Obituary.

REV. CHARLES HENRY BULMER.—The Rev. Charles Henry Bulmer, M.A., passed away on February 15, in his 85th year. For 49 years he was rector of Credenhill, Herefordshire, almost within sight of the former realm of Thomas Andrew Knight at Wormsley. Up to the last he was a keen pomologist and rosarian, and was one of the founders of the National Rose Society. The effect of his work in pomology is to be seen in many plantations of fruit trees, and in more lasting mode in the first great work on pomology that this country has produced: the *Herefordshire Pomona* of Dr. Graves Bull and Dr. Robert Hogg. We understand that it was largely due to his initiative that this work was ever produced, and many of the specimens which were figured therein were selected by him. He was a constant contributor in former days to *The Journal of Horticulture*, over the *nom de plume* of *Herefordshire Incumbent*. His spirit of enquiry led him to experiment in the making of cider and perry, and further to imbue his two sons with his interest in the subject, an interest which has culminated in the growth of what is probably the largest cider works in existence. Beloved by all in his old parish, gentle and retiring, he was nothing in helping others to the love that he had acquired.

GÉRARD OP'T EYNDE. We regret to announce the death of Monsieur Op't Eynde, a well-known fruit grower of Hoeylaert, near Brussels. Monsieur Op't Eynde was not only a grower himself, but for very many years he had taken a great interest in the associations of fruit growers in the district in which he lived. He filled for twenty years the office of president of the Syndicats of Belgian Grape Growers, and that of president of the Brussels Horticulturists' Auction; he was also vice-president of the Belgian Horticultural Council. Deceased was the step-father of Monsieur H. van Orshoven, who came to this country at the commencement of the war, and has charge of the London office of the Belgian Ministry of Agriculture. Monsieur van Orshoven was for some time on the staff of the *Gardeners' Chronicle*, and conducted the French and Belgian page published in this paper for the benefit of Belgian gardeners in this country for over a year after the war broke out.

MARKETS.

COVENT GARDEN, *February 20.*

Cut Flowers, &c.: Average Wholesale Prices

	s. d.	s. d.
Arums—		
— (Richardias), per doz. blms.	4 0– 5 0	
Azalea, white, per doz. bunches	5 0– 6 0	
Camellias, white, per doz.	2 6– 3 0	
Carnations, per doz.		
— blooms, best American var.	3 0– 4 0	
Croton leaves, per bun.	1 3– 1 6	
Daffodils (single), per doz. bun.—		
— Emperor	9 0–10 0	
— Golden Spur	8 0–10 0	
— Henry Irving	3 0– 4 0	
— Princeps	4 0– 6	
Freesia, per doz. bun.	3 0– 4 0	
Heather, white, per doz. bun.	9 0–12 0	
Lilium longiflorum, long	4 0– 5 0	
— Lancifolium album, long	3 0– 4 0	
— — rubrum, per doz. long	4 0– 5 0	
— — short, per doz. blooms	3 0– 4 0	
Violets, per doz. bun.	9 0–12 0	

French Flowers: Average Wholesale Prices.

	s. d.	s. d.
Anemones, double pink, per doz. bun.	–	
— single, mixed	9 0–18 0	
Mimosa (Acacia), per basket	6 0– 8 0	
Narcissus, per basket—		
Paper white	6 0– 8 0	
Narcissus, con.—		
Glorosa	8 0–10 0	
— Double Yellow	6 0– 8 0	
— Soleil d'Or	4 0– 6 0	
Ranunculus, scarlet, per doz. bun.	15 0–18 0	
Violets, Parma, per bun.	5 0– 6 0	
— Single	3 0– 4 0	

Cut Foliage, &c.: Average Wholesale Prices.

	s. d.	s. d.
Adiantum (Maiden hair Fern) best, per doz. bun.	8 0–10 0	
Asparagus plumosus, long trails, per half dozen	2 6– 3 0	
— — medium, doz. bunches	18 0–21 0	
— Sprengeri	10 0–15 0	
Berberis, per doz. bun.	5 0– 6 0	
Carnation foliage, doz. bunches	4 0– 5 0	
Cycas leaves, per doz.	3 0– 6 0	
Ivy leaves, per doz. bunches	2 0– 3 6	
Moss, sprgs bun.	7 0– 8 0	
Smilax, per bun. of 6 trails	9 0– 2 6	

REMARKS.—A plentiful supply of cut flowers continues to arrive from France and the Channel Islands. These consignments arrive in better condition despite the rougher weather as some of the flowers are from four to five days on the journey. Arrivals of French flowers continue very erratic. Carnations are now more plentiful and easier in price for the month of bloom as only of medium quality. The choicer varieties are Enchantress, Delight, Lady Margaret Dobbie, Rose Pink, Winsor, Beacon, Comet, Triumph, and Cardinal (crimson). A few white, mauve and bronze Tulips are still to be had, their prices remain firm. A larger supply of Roses would be welcomed. A few blooms of Sunburst are offered at exceptional quality. There is an abundant supply of Single Violets and Snowdrops. Primroses are making their first appearance. There is now a good supply of English-grown Daffodils and Phenomenal Narcissus. Arums (Richardias) and Lilium longiflorum are sufficient for the demand. Lily of the Valley is scarce in character and the condition good. Accumulations have been arranged for a limited quantity of pot plants and pots. Ferns and Palms are in short supply. The chief flowering plants are Cineraria, Daffodil, Cyclamen, Margueritas, Begonias, Primula and Azalea.

Vegetables: Average Wholesale Prices

Parsley, per doz.	0 6– 0 0	
Parsnips, per bag	0 0– 0 0	
Peas, per lb.	0 6– 0 0	
Potatoes, per cwt.	3 0– 3 6	
Radishes, per doz. bunches	1 0– 1 6	
Rhubarb, per bundle	1 0– 2 0	
Salsafy, per bundle	1 0– 1 6	
Scorzonera, per bundle	1 0– 1 6	
Seakale, per punnet	1 0– 1 6	
Shallots, per lb.	0 6– 0 8	
Spinach, per bag	1 6– 1 8	
Tomatos, per lb.	0 6– 0 8	
Turnips, per bag	1 6– 2 0	
Watercress, per doz.	0 10– 1 0	

Fruit: Average Wholesale Prices.

	s. d.	s. d.
Almonds, per cwt.	170 0	–
Apples:—		
— cooking, per bus.	10 0– 20 0	
— Russets, French, in cases of about 60 to 70 lbs.	34 0– 42 0	
Dates, per box	3 4	–
Grapes, Black Alicante, per lb.	0 0– 0 0	
— Almeria, per barrel (42 doz. lbs.)	4 0– 70 0	
Grapes, con.—		
— Gros Colman, per lb.	4 6– 8 0	
Lemons, per case	38 0– 46 0	
Nuts, Barcelonas, per bag	150 0	–
— Cob, per lb.	1 3	–
Oranges, per case	75 0–120 0	
— navel, per case	55 0– 60 0	
— Tangerines, per box	14 0– 15 0	
Walnuts, kiln dried, per bag	52 0–130 0	

REMARKS.—The market continues to be fairly well supplied with English Apples. Supplies of French Apples have increased during the week. Grapes are a much shorter supply. Spanish White (Almeria) Grapes are fairly plentiful, sold in barrels of about 42 lbs., also by the 12 lbs. Oranges and Lemons are to hand in limited quantities. The principal forced vegetables on sale are Asparagus (English and French), Beans (Dwarf), Potatos, Mushrooms, Cucumbers, Seakale and Peas. Some good samples of Rosen Cauliflowers are on offer. Vegetables and roots are plentiful.

F. H. Bo Covent Garden Market, February 20, 1918.

DEBATING SOCIETIES.

READING AND DISTRICT GARDENERS.

A Chrysanthemum Party presided at the meeting held on Monday, January 28. The subject of the discussion was the three best cropping and cooking Potatos in the first early, second early and maincrop sections, introduced by Mr. H. C. Loader, The Gardens, Ethelgh Park. The number of the votes given by the members were: First early, May Queen (29), Sharpe's Express (10), Empress (10) and Ringleader (10). Second early, Windsor Castle (29), British Queen (10) and Epicure (5). Maincrop, Arran Chief (19), Epicure (19), and King Edward VII. (16). During the evening Mr. Shuttleworth, from the Food Production Department, gave a short address on Potato-spraying.

BATH GARDENERS'.

The first paper read to members of the Bath Gardeners' Debating Society during the present session was by Mr. W. Scrimgeour, entitled "The Right Hon. Walter Long." Reed Abbey, Mr. T. Parr and Mr. Reed Lower a good contribution. Mr. Scrimgeour dealt with matters relative to fruit generally, and discussed various methods of Potato production in the north and elsewhere, as well as the selection of seed Potatos and the cultivation of the Onion and the Pea. On the president and four ordinary months the above selected and the Silver Medal for the best exhibit of the greatest number of varieties in pots was finally awarded to Mr. H. Parr.

CATALOGUES RECEIVED.

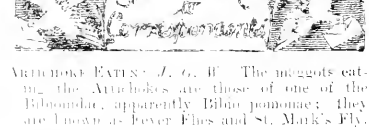
Thos. [illegible] Reed Bo[illegible] Seed[illegible]

A. Dickinson & Sons, King's Road, Chelsea, S.W.—Seeds.

GARDENING APPOINTMENTS.

MR. L. JONES, for 7 years Gardener to Col. W. A. W. Lawson, Sawdon Lodge, McPon Mowbray, as Gardener to C. C. CRUSE, Esq., Langwood Hall, Newark, Nottinghamshire.

MR. S. LEGG, for 5½ years Gardener at Dalton Hall, Rydal, and for 1 year at Newstead Abbey, and previously for 5½ years under Mr. F. JOHNSON, as Gardener to Lt.-Col. NEVILLE CROOME, Walter Priory, York.



ARTICHOKE EATEN.—*J. G. H.* The maggots eating the Artichokes are those of one of the Bibionidæ, apparently Bibio pomonæ; they are known as Fever Flies and St. Mark's Fly.

FRUIT STOCKS.—*Subscriber.* The Apricot is raised from seed as well as by budding or grafting. Various stocks are used to suit different varieties of the fruit. The Brussels, Mussel, Black Damask, and St. Julien Plum stocks are used for budding or grafting, special knowledge being necessary for selecting the stock most suitable for the variety of Apricot to be raised. Peaches are best raised by budding the Black Damask and St. Julien Plum stocks being among the most suitable. Plums are raised by budding and grafting. The Mussel is probably the best stock for standard Plums. The Myrobalan (from cuttings) is also used. The "Common Plum" is named by one authority as a suitable stock for dwarf trees.

GRAPES: *W. T. W.* After you have thoroughly cleansed the house, dress the rods with Gishurst compound, rubbing it well in with a stiff brush. Prick up the border and top-dress it with Le Frutier. Close the house, but do not use fire heat, for a fortnight, then use a little artificial warmth to keep the temperature of 50° at night, gradually increasing to 65° by the time the vines come into flower, with a rise of 10° during the day, with ventilation. Examine the border at short intervals, and water it copiously once a fortnight or once a month, according to the nature of the soil.

NAMES OF FRUITS: *F. S.* Striped Apples, Colonel Vaughan (syn. Kentish Pippin); greenish, Isle of Wight Pippin.

NAMES OF PLANTS: *R. H.* Veltheimia viridifolia.

PEACHES: *W. T. W.* Peach trees in late houses should be pruned at once, and no more shoots should be left than are necessary to secure an evenly balanced tree; train them about 4 inches apart. Tie the shoots to the trellis and syringe the trees with quassia extract. Keep the house cool until the trees come into bloom, when a dry, buoyant atmosphere should be maintained, and a temperature of 50°, with ventilation. Fork the surface of the border lightly, and dress with Le Fruitier manure, according to directions, using a little fresh compost as a topdressing. Syringe the trees regularly after the fruits are set, and see that the roots never suffer for want of water.

POTATOS: *J. K.* The varieties Keer's Cigarette and Skerry Blue are not listed in any of the leading Potato merchants' catalogues, and we do not know where they can be procured. They may still be grown in some private gardens.

PROTECTING APPLE TREES: *Kildare.* Hay bands would not injure the Apple trees, and these could be smeared over with tar, but they would harbour many insect pests during the winter months, and last only for one season. The cheapest and best protection from sheep or rabbits is 1½-inch mesh wire netting, 2 to 3 feet high, cut 9 inches to a foot wide. Place two stakes to the tree and fasten the wire to them; the wire should be sunk a few inches in the ground.

SEAKALE: *A. J. C.* A punnet of Seakale as sold in Covent Garden Market contains 3 lbs. in weight—approximately one dozen crowns.

SULPHUR ON PIPES: *J. H. P.* Flower of sulphur painted on hot-water pipes are injurious to Peaches in the early stages of their growth, and will kill soft-wooded plants, such as Calceolarias and Cinerarias. After growth is matured, sulphur may be used with advantage if the pipes are not made too hot; but be careful to see that the foliage is dry when the sulphur is employed. It would not be particularly efficacious as a preventive of disease in Tomatos, and for this purpose the plants should be sprayed with a suitable specific. Syringe the plants occasionally with quassia extract and dust with soot to protect them from rabbits.

TOMATOS: *W. T. W.* The disease may possibly have been present in the fruits, and as it is impossible to remove the soil, this should be dressed as you suggest and left at least a fortnight before planting. Thoroughly cleanse the glass house, and, if empty, burn a few handfuls of sulphur in it. Mix the bonemeal with the road scrapings, and keep the potash and fish manure for dressing the borders later, when the plants are in fruit.

COLLECTING TREE SEEDS.

IN pre-war times the great bulk of forest tree seeds used in this country was obtained from Continental sources, but for several years to come we shall be compelled to rely mainly on seeds from our own woods and plantations. With a well-arranged system of collecting and harvesting tree seeds there is no reason why there should be a scarcity, as we have ample supplies of old trees of the various kinds that will be largely pollarded in the near future, from which the necessary amount of seeds may be collected. Great care will, however, be necessary in choosing the particular trees from which seeds are to be collected, the best being produced by healthy trees in the prime of life and grown in conditions favourable to their perfect development. Unhealthy trees will often bear a heavy crop of seed, but although the inducements to collect such are great, where quantity and not quality is the point of consideration, they should be discarded, and those from the most robust specimens carefully selected. Trees growing in mining districts or wherever atmospheric impurities are present should be ignored by the seed collector, as should any others growing in unfavourable soil and climatic conditions.

Such trees as the Scots, Corsican, Austrian, and Weymouth Pines, the Larch and Silver Fir, produce cones freely; while amongst hardwooded species, the Ash, Oak, Beech, Elm, Poplar, and Birch may be propagated in large quantities from home-saved seeds.

Regarding the best way of collecting tree seeds little need be said, the exigence of the case pointing out the best method to be adopted. The seeds of not a few trees may be collected as they fall, and this especially applies to those of the Oak, Beech, and Elm. The seeds of these trees may be swept into heaps and gathered in quantity from beneath desirable trees.

In the case of the various Coniferae this method of seed-collecting will not answer—indeed, in the majority of instances such seeds should be gathered, or, rather, picked from the trees, just before they become fully ripe, as in falling the seeds get loose from the cone-scales and are lost. When collecting the cones of Coniferous trees, a long, light, hooked staff with which to draw the branches towards one will assist in procuring an abundant supply. A bag or satchel should also be used by the seed-collector, and into this may be put such kinds of cones as fall readily apart, and from which the seeds easily escape and are lost. Sometimes, as in the case of rare seeds and when only a few cones are borne near the top of the tree, the seed-collector must have recourse to climbing up the stem and branches; but in such cases, so as to avoid injury to the bark, he should be provided with a pair of rubber shoes or slippers. Great care is required in the collecting of such seeds as those of Abies nobilis and A. Nordmanniana, the cones, when fully ripe, falling to pieces on the slightest touch. This, however, applies equally to almost every species of Abies, whereas, with the Pines and Spruces, the cones remain intact for an indefinite period of time, and that, too, although the seeds may have fallen out on becoming ripe.

After being collected, the seeds of all trees, except those which are mixed with sand to promote the rotting of the seed cases, should be thinly and evenly spread out in a sunless spot until thoroughly dry. They may then be deposited in a cool, airy place, and in thin layers, until wanted for sowing. As much of the chaff covering of the heap as is all important, and should never be neglected. The smaller and less common seeds may, for convenience, be hung in calico bags, but these, too, should be occasionally examined to ascertain if they are damping or heating.

The number of plants of various kinds that may be expected from a bushel of seed of average quality varies very much. The quantity may be approximately given as follows:—Horse Chestnut, 2,500; Oak, 6,000; Spanish Chestnut, about 3,000; Walnut, 5,000; Norway Maple, 12,000; Sycamore, about 12,000; Ash, 14,000; Beech, 10,000; Elm, 1,000; Birch, fully 16,000; Holly, 17,000; Scots Fir, 9,000. To 1 lb. of seed: Spruce Fir, about 9,000; Larch, 3,000; and the Cluster Pine, Silver Fir and some others, about 500 upwards.

For convenience in regulating orders for sowing, the following table will show at a glance the approximate and relative number of seeds of the various commonly cultivated forest trees contained in 1 lb. weight:—

Abies nobilis	About	19,400
Abies Nordmanniana		10,000
Ash		6,500
Beech		2,700
Douglas Fir		95,200
Horse Chestnut		36
Hornbeam		9,963
Larch		65,000
Lawson's Cypress		131,400
Lebanon Cedar	About	10,800
Norway Maple		4,000
Oak		100
Pinus austriaca		35,000
Pinus Laricio		45,000
Pinus Pinaster		12,000
Pinus sylvestris		75,000
Spruce		64,500
Silver Fir		14,960
Sycamore		4,624
Walnut		36

These figures must only be taken as approximate, the seed of various trees of the same species seeming to vary in number to the pound in a marked degree. The results of careful analyses of one or two kinds may be cited as examples. In one case the number of seeds in 1 lb. weight of Scots Fir was 69,600, while in another it had increased to 90,600; and in the Larch the numbers were 53,000 and 68,000. These differences are, however, readily explained by the individual seeds being heavier in one case than in another, probably owing to the age and health of the tree from which they were collected, the situation and exposure to which it was subjected, and other circumstances. However, for all nursery purposes the above figures may be accepted as a fair standard.

The time of collecting and the after-management of the different forest seeds vary so much that a brief description of those kinds most commonly planted will be found useful.

Alder seed should be gathered from the trees in October, and sown in spring—say, May.

Ash seeds are ripe in October, when they should be collected and kept in moist sand during the winter, to be sown in March.

Austrian, Corsican and Weymouth Pine seeds are treated in every respect like those of the Scots Fir, varying the kiln heat according to the looseness of the cone-bracts.

Beech seeds are collected in October and November, placed in sand, and sown in April. The young plants are readily affected by frost, and should, therefore, not be sown earlier than the time mentioned.

Birch seed should be collected from the trees just before it becomes ripe in August, else it is scattered broadcast, and lost for cultivation. March is the time of sowing.

Cupressus Lawsoniana seed is usually ready for collecting in October, but should not be sown before the first week in April.

The seed of Douglas Fir is, in most cases, readily removed from well ripened cones by threshing or by pulling the cone to pieces, but, in some instances, particularly where the quantity is large, kiln-drying is resorted to. The seeds are ripe in December, and should be gently watered and sown in May.

Elm seeds are ripe in June, when they may either be sown at once, or mixed and kept in stock for planting in March or April.

Hawthorn seed, or berries, may be sown when collected, or the outer coating rotted off by keeping them during the winter in moist sand.

Hazel Nuts may be collected in autumn and sown at once, or kept till spring.

Holly berries require to be placed in sand for about eighteen months to cause the fleshy outer coating to rot, and may be sown in March. The mixture of sand and berries, which should be in about equal proportions, should be turned frequently. They are usually sown with the sand with which they have been mixed.

Horse and Spanish Chestnut seeds may be taken together, the collecting and sowing being nearly alike in both cases. They are ripe by the beginning of November, and may either be sown at once or kept till spring. One seed to 4 square inches will be close enough to plant.

Acorns may be gathered or swept from the ground in November, and either sown at once or stored in a cool, dry place till spring. One Acorn to every 4 square inches will be ample in the seed-bed. Sow in spring or autumn.

The cones of Scots Fir are better not collected till early in January, and the time may even be extended to March. When quite ripe they have changed from bluish-green to a light grey colour. As the cones part tardily with the seeds artificial means have to be resorted to. This consists in placing the cones thinly over a kiln heated to a temperature of from 75° to 112°. They should be turned every third hour, and after about thirty hours the kiln should be

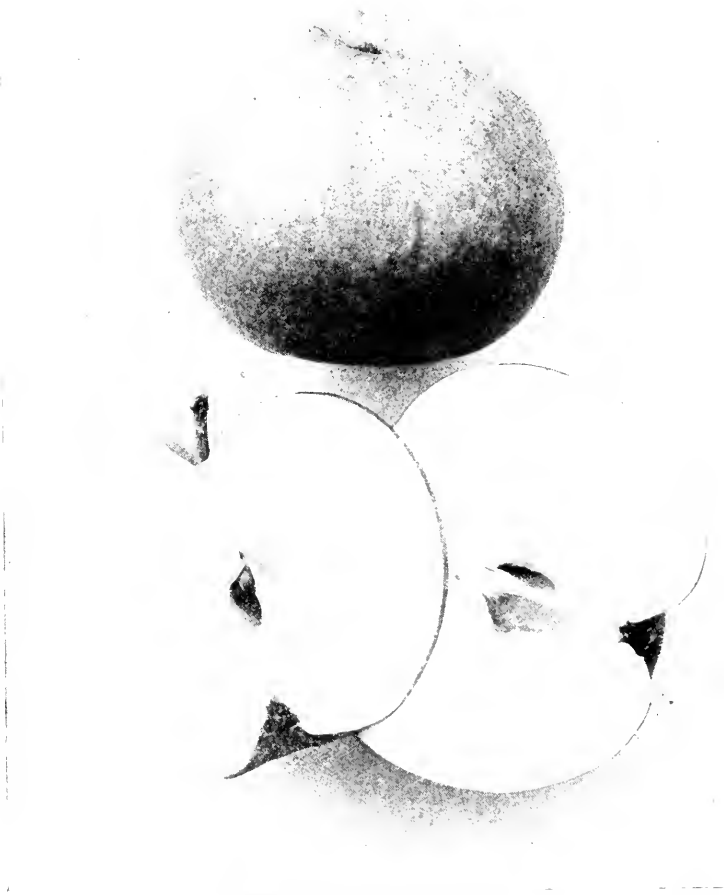

Fig. 37.—Dessert apple Laxton's Superb

Larch cones, when ripe, are of a rather bright brown colour. They require to be collected from the trees. This should not, however, be done till spring, though occasionally they are gathered in December. The scales part from the seeds far more readily than those of the Scotch Fir, and consequently require less heat when in the kiln.

Maple seeds are ready for collecting about October, and should not be sown till the beginning of April.

Mountain Ash, indeed all members of the Pyrus family and others of a like kind, require the berries to be placed in sand, and when the outer fleshy coating has rotted away they may be sown either in autumn or spring.

cooled down and the cones extracted as quickly as possible. By beating with a flail the seeds are readily removed from the cones, and it is best to do this before the latter have cooled or immediately they are removed from the kiln. The seeds are then swept together and collected, and stored until needed for sowing. When not required for sowing at once, the seeds should be thinly spread out on the floor and slightly moistened with water from a fine-rose watering can. They should then be turned about until perfectly dry before being stored.

Silver Fir seed does not require much, if any, artificial warmth to cause it to part from the cone. By placing the cones in the sunshine, and beating and turning them freely, the seeds come out without much trouble. In all cases, however, wherever possible, it is wise policy to dispense with artificial heat or kiln-drying, as, unless this is carried out most carefully, the vitality of the seeds is greatly impaired.

Sycamore seeds are ready for gathering in October, but should not be sown till the end of March or beginning of April.

Walnuts are collected, when ripe, in autumn, and sown in late spring.

Yew seeds are usually washed free of the pulpy matter before being sown.

In the case of large seeds, such as those of Araucaria imbricata, Pinus Sabiniana, and P. macrocarpa, the best way is to cut the cones to pieces and carefully remove the seeds, but this should be performed with great care, so that the hard seed coating may not be injured.

With Conifers in general I have invariably found it the best plan to allow the seed to remain in the cones until wanted for sowing. By keeping the cones in a cool, dry place, and occasionally turning them, there need be little fear but that the seeds will turn out well. *D. Webster.*

NEW APPLES FROM BEDFORD.

In the issue for October 20, 1916, p. 163, we gave some particulars of the work extending over a period of twenty-five years done by Messrs. Laxton Bros. in the raising of seedlings of various kinds of fruit. On a visit to the nursery we were shown some thousands of crosses which had been made, principally amongst Plums and Apples, with the names of the parents, dates of pollination, and other information recorded in the pedigree book. In the autumns of 1915, 1916 and 1917, the firm showed a considerable number of the new fruits at the fortnightly meetings of the Royal Horticultural Society, some of which gained awards. At the meeting on January 29 last they exhibited a number of the seedling Apples, which attracted attention from fruit growers. It was unfortunate that the fruits were not in first-rate condition, circumstances having made it imperative to gather them before they were quite ripe. In consequence the majority presented a somewhat shrivelled appearance, and were not in the best form. The flavour of most of the Apples was exceptionally good, and the Committee expressed a wish to see certain of the varieties again another season, when it was hoped they could be shown at their best.

The principal parents were Cox's Orange Pippin, King of the Pippins, Court Pendû Plat, Ribston Pippin, and Wyken Pippin. A handsome variety, a cross between Wyken Pippin and Cox's Orange Pippin, is named Laxton's Superb (see fig. 38). The fruit is rather larger than that of Cox's, and, as will be seen on reference to the illustration, it is of somewhat similar shape. The tree is stated to be a very heavy cropper, and the variety should furnish a valuable late-keeping dessert Apple. Another seedling of extremely good flavour was named W. Watson; it was raised from Court Pendû Plat crossed with Cox's Orange Pippin, and is, apparently, a very late-keeping variety. The fruits are of medium size.

A promising unnamed seedling was raised from Allington Pippin crossed with Cox's Orange Pippin. The fruits take a very high colour, and are about the size of Cox's Orange Pippin, with a flavour almost equal to that fine variety. The season of this fruit is said to be from November to February. A variety of very sweet flavour, of medium size, is the result of a cross between Court Pendû Plat and Ribston Pippin. The flesh is firm, and of a greenish-yellow colour, which generally betokens good quality in an Apple. The first-named parent

was used with the object of securing late blossoming, which is an advantage in enabling the flowers to escape injury by spring frosts. The "Wise Apple," as Court Pendû Plat is called on account of its late-flowering habit, was also used as a parent with other varieties, including Cox's Orange Pippin.

ORCHID NOTES AND GLEANINGS.

CYMBIDIUM ALEXANDERI WARREN HOUSE VARIETY.

A number of small seedling plants flowering for the first time in Mrs. Bischoffsheim's gardens at The Warren House, Stanmore (Orchid grower Mr. H. Haddon) well show the beauty and variation in this favourite cross between C. insigne and C. eburneo-Lowianum. The fine white or blush flowers vary considerably in the rose or light purple markings of the lip; in one form the ground colour is pale yellow with red-brown markings. The most remarkable is The Warren House variety, which has flowers of wax-like texture blush-white in colour, with a slight rose line in the middle of the petals. The base of the lip is closely lined with deep claret colour, which merges on each side in front into patches of dark claret-purple. The front lobe is white, with dark purple spots within the margin.

ODONTOGLOSSUM FASCINATOR.

A flower of this cross between O. crispum and O. Adrianae (crispum × Hunnewellianum) is sent by Mr. Jas. Renwick, gardener to Colonel Leith, Greycourt, Riding Mill-on-Tyne, in whose gardens it was raised. The flower, which is equal to O. crispum in size, has equally broad sepals and petals of a clear white, the sepals bearing several very large, bright claret-coloured blotches, and the fringed petals a cluster of blotches of the same colour, with smaller spotting on the basal half. The lip still bears distinct traces of O. Hunnewellianum in the fimbriate margin with reddish markings, and the curled, apiculate apex. A large chestnut-red blotch appears in front of the yellow crest.

HYBRID ORCHIDS.

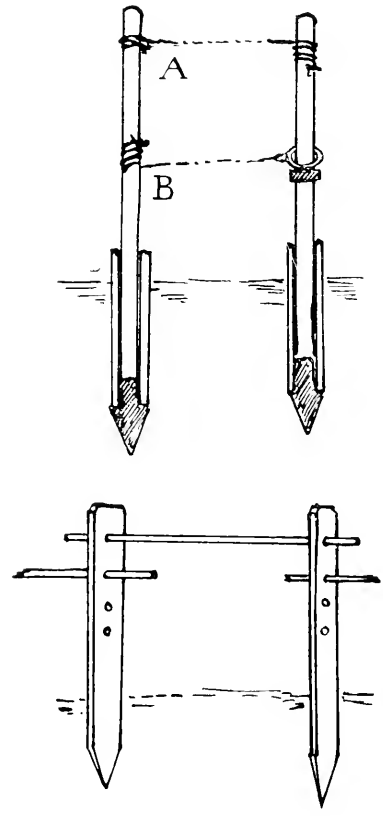

Fig. 39. Simple supports: above, iron piping inserted in sockets; below, wooden pegs for carrying cane rails.

CORRECTIONS.

For Brasso-Laelio-Cattleya Anzac var. Vesuvius, in the table on p. 3, Jan. 5, read Sophro-Laelio-Cattleya.
The parentage of Laelio-Cattleya Gatton Yellow recorded Mar. 11, 1916, p. 140, is Haroldiana × Ophir, not luminosa × Ophir.

SIMPLE SUPPORTS AND SHELTERS.

The support illustrated in fig. 1 (above) is a means of using a stretched string or cord, the tension of which can be regulated from time to time. My main use of it has been for Asparagus, which I have in long double-row lengths near a path; without support the winds we experience break off and bend down a number of the shoots. The uprights are made of old galvanised piping, which, when split by frost, can sometimes be removed from builders' yards for little more than mere thanks. The sockets for driving into the soil may be about 2 or 2½ feet long, and are plugged with a pointed piece of wood; if they are of 1-inch pipe, the main rods should be of ¾-inch piping, which slips nicely into them. The main rods may be 4 or 5 feet long, as required, remembering that a foot or more will be below the ground level. At *A* is shown the simple arrangement where only a single string is needed; the two ends are tied on the rods with a rolling hitch, and by rotating the rod the string is wound on to the desired tension; the small diameter of the rod and the friction in the socket prevents unwinding. In this case a fixed stick only is needed at the one end. If two strings are needed the arrangement *B* must be adopted to make independent rotation of either rod possible; a loosely fitting ring or hook of stout wire replaces the hitch of the string, and a collar of some material is wound and tied on to prevent the ring from slipping down; in the figure this collar would be at the letter *A* on rod, when the gear is as figured with the ring on the other. Ordinary coir twine is suitable, as it does not vary so much with weather, as, for instance, does manilla twine. It is little trouble to give an occasional twist should need be. In long lengths fixed stakes at about 10 yards or so distances will help to support and prevent sagging of the cord.

A very simple raidisseur, which is used on large Loganberry plantations about here, is easily made by blacksmiths. It consists of a flattened ring like the link of a chain made of flat bar iron. The flat sides are drilled to take a ⅝ or ¾ bolt, which, too, is drilled to take the end of the wire. The wire is passed through the upright support against which the "link" beds; stretching is done by turning the bolt and fixation by locking down the nut, two spanners being required. For small and temporary garden work a mortise slot cut in a piece of Beech or other hard wood might be of good service.

A simple support made of pegs and canes is shown in the bottom figure. In its shorter form I use it for supporting dwarf Beans which are to ripen seeds, though some have to undergo the cruder method of being swathed over from time to time. This swathing does not entirely prevent loss by moulds in wet weather, especially with the later sowings. In higher form it is useful for Broad Beans, which are apt to be blown down by gales; green Corn and other crops may be aided, and one year a Pea, which was said to be only M.30 high, grew to M1·25, and was saved from collapse by a few canes. The pegs may be 2½ to 3 or 4 or 5 feet in length, as the case may be; condemned cask staves do excellently for the former when cut and split, and last for years if occasionally doped with preservative. A series of holes is drilled about equidistant for the canes to pass; ⅝ inch gauge will suffice for the ordinary 4-feet and selected 9 feet canes. The method of use will be clear from the illustration, but when long canes are used a peg is preferably threaded on a cane at its middle. I use these supports in independent rows obliquely across narrow Strawberry beds for supporting the netting; there is nothing to catch the netting, which is readily thrown on or off. 9 foot canes are used, and the obliquity is guided by the width of the bed.

The same perforated pegs are useful for hold-

ing frost shelters when arranged as follows: Ordinary wire netting "Pea-guards," or pieces of wire netting of wider mesh and sufficient strength for the breadth selected, are bent to a slight arching only; strips of waterproofed paper are attached on the upper side by two or three zigzag lacings of twine. Canes of sufficient length to project somewhat beyond their ends are then tied at a few points along each side; the whole then looks somewhat like a Red Cross stretcher, but upside down. The ends of the canes are tucked into the holes in the pegs in succession along the row. Protection from early and late frosts may thus be obtained and from light and air; often plants thus sheltered in non-frosty weather will forge ahead of all others. *H. E. Durham.*

ON INCREASED FOOD PRODUCTION.

VEGETABLE PLANTS FOR ALLOTMENTS.

The Committee of the Elstree Cottage Gardens Society has set aside land for the sowing and raising of large numbers of vegetable plants suitable for growing on the adjoining allotments. The plants will be raised by a skilled gardener and sold at a reasonable price to allotment and cottage garden holders. The plan is well worthy of adoption generally, as the obtaining of plants in this way will save much trouble to those who are not in a position to attend to the wants of the seedlings. Seed from a reliable source can be purchased cheaper in bulk, and the best stocks and varieties obtained. Members of the Brassica family, Celery, Onions, and Leeks, are amongst those which can be easily raised under these conditions, and the venture should prove advantageous in every way to those concerned. *Edwin Beckett.*

DEGENERATION IN POTATOS.

Three seasons ago I bought seed of Up-to-Date Potatos from Cambridgeshire. The first year after planting the crop showed marked signs of weakness. As an experiment, planting from this stock was continued, and by the third season this stock had become so weak that many of the tubers produced but very little growth, which was infested by leaf curl; consequently the yield in small tubers was much greater than the yield in wan tubers.

Now by this extra yield in seed tubers one can see how easily trouble becomes multiplied, especially when planting is continued for a few seasons from a degenerate stock.

Last season I selected a few tubers from the healthiest roots of these Up-to-Dates, with the intention of giving them a trial this coming season; but I have been informed by a grower who has already tried this experiment that even from these selected tubers a percentage of weak plants will result each season, which is a proof that such stocks are suffering from inherent weakness.

Such degenerate stock should not be planted, or put on the market as seed tubers. It would be a boon to the cultivator, and assist in our food supply, if the authorities would immediately put an end to these weak stocks by buying the tubers for mixing with flour.

I do not imply that all stocks of Up-to-Dates are degenerating, but I do believe that when inherent weakness attacks an individual stock that no amount of selection or even a change in soil will bring back the lost vitality.

Last season good and bad stocks were planted as seed tubers were scarce: therefore it is highly important this season that growers, large and small, should make a thorough selection of their stocks of seed Potatos, and plant only from such varieties that grew and cropped well last season. *G. H. H. W.*

NATIONAL KITCHENS, ALLOTMENTS, AND PIGS.

Now that there is every prospect of the "National" kitchen materialising, I should like to suggest that, where possible, allotments be cultivated for their benefit by voluntary labour.

There must be a large number of people who have not sufficient time to cultivate allotments of their own, but who would gladly give one or more evenings a week, or even devote week-ends, to a healthy outdoor occupation, with the knowledge that they were thereby helping their country.

Most local authorities have allotment committees who could organise and supervise the movement.

Pigs might be kept on the refuse from the allotments generally, and the refuse might also be collected from any eating houses in the locality and fed to the pigs, instead of carted to the dust destructor. The pigs would also supply a certain amount of manure to the land.

This would, in a way, be a revival, on a small scale, of the old manorial system of land cultivation, and the workers might be encouraged and rewarded with a certain proportion of the produce of the land. *Sidney Oetzmann.*

SOY BEAN.

On p. 33 Mr. Lynch mentions the use of the Soy Bean as a Coffee substitute. Pailleux and Bois give high praise (*Le Potager d'une Curieux*, 1885) in this respect. "Le Soya est sans contredit le meilleur de tous les succédanés du café. Il donne un bon café au lait dont l'arome est sensiblement celui du Moka." In Haute Garonne, Tyrol, and other districts is it called "Fève de Café." "Si tous les cultivateurs consacraient tous les années dans leurs jardins un petit espace au Soya, ils obtiendraient sans bourse délier le café nécessaire au dejeuner de leurs familles." Sowing is advised from April 25 to May 10, after rain. The distance apart is most important, and should be not less than M.50 for S. d'Etampes, and M.35 for other sorts. This Bean is excellent as "flageolet." *H. E. D.*

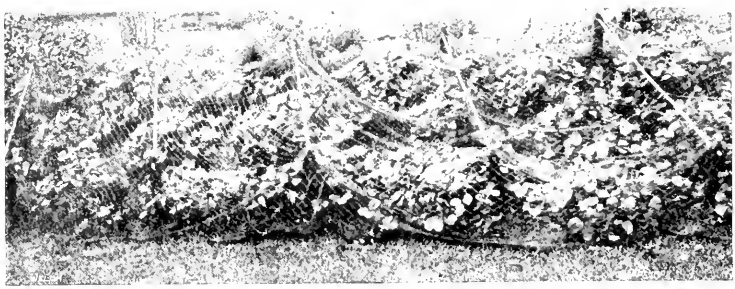

Fig. 40.—Simple method of protecting a strawberry bed.

(See p. 87.)

The Week's Work.

THE KITCHEN GARDEN.

By F. Jordan, Gardener to Lieut.-Col. Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Autumn-sown Onions.—Take the first opportunity, as soon as the soil is in a suitable condition, to transplant autumn-sown Onions. To obtain the best results select ground that has been trenched and manured as recommended for the summer crop. Home-grown Onions are sure to be a valuable crop next season, and if plenty of plants are available a large area of ground should be planted. Lift the plants carefully and put them in rows made 15 inches apart, allowing a space of 6 or 8 inches between the plants in the rows. Make the plants firm in the ground and water them, if necessary, directly after they are planted. Stir the soil between the rows on frequent occasions until the plants are well established.

Spring-sown Onions.—Make a sowing of Onions on the first favourable occasion, selecting ground which has been thoroughly prepared for this crop. Give the soil a light dressing of lime and a heavier dressing of wood ash, or any other suitable material of a light nature. Such applications will help to bring heavy soil into a workable condition. Fork the soil lightly and level the bed for sowing with a wooden rake. Sow the seed thinly in shallow drills made not less than 12 inches apart, and cover the seed by treading the displaced soil in the drills again. When the rows have been well trodden in this manner make the surface level again by the use of an iron rake. Onions raised from seed sown in boxes, as recommended in a previous calendar, should be transplanted before they become spindly. Place the largest seedlings in a box by themselves and continue to grow them in a light position in a house or frame having a temperature of 55°. Keep the atmosphere close until the plants are well established, and afterwards gradually increase the amount of ventilation to harden the plants in readiness for setting out-of-doors about the middle of April.

Leeks.—Prick out early Leeks, and make the principal sowing of this vegetable as soon as the soil and weather are suitable, in a similar manner to that advised for Onions.

Broad Beans.—Make another sowing of Broad Beans to obtain plants for early supplies. Choose the Windsor type, following with such varieties as Seville, Long Pod, and Bunyard's Exhibition where the larger-podded types are desired.

General Remarks.—March is one of the busiest months in the kitchen garden, and arrears of work should be completed forthwith in order that nothing may hinder future sowing and planting operations. On light soils work may be pushed forward in almost all kinds of weather, but heavy ground is best left alone until more favourable conditions prevail. Difficult weather conditions generally prevail at the beginning of March, but remember that opportunities lost now can never be regained this season. As the sun gains power the ventilation of houses and frames should be freely increased during the day, but close the lights early with sun-heat, and cover them at night with a suitable protection during very cold weather. On wet days examine roots in store and prepare soils in readiness for future use.

THE HARDY FRUIT GARDEN.

By Jas. Hudson, Head Gardener at Gunnersbury House, Acton, W.

Watering Fruit Trees.—If the soil in which fruit trees are growing is suspected of being dry let it be watered copiously. Trees, for instance, that are planted against walls in borders sloping to the paths, are very liable to become dry at the roots. In such instances water the trees freely before they come into flower. Apricots, too, may need this attention. The soil about young trees that were planted last autumn, having now become settled

to its former level, should be trodden when the ground is rather dry, and afterwards watered. Those planted against walls may be nailed or tied to the wires. Such trees should be pruned moderately the first season.

BRAMBLES.—The pruning and training of such berry-bearing plants as the Loganberry, the Phenomenal Berry, the American or Cut-leaved Bramble, and the Loxberry having been completed, the roots should be mulched with manure. I am most favourably impressed with the Loxberry; the plant repays well for generous treatment, and in ordinary conditions grows strongly. All of these berry-bearing plants should be given plenty of room to develop. Our plants are supported on strained wire fencing about 3 feet in height; the growths in our case are already nearly all tied, and a top dressing will be given in the general clean up that will follow. Being short of good stakes I have had recourse in some cases to the market gardener's method of tying the Raspberry canes in bundles. This system will answer well as the growths are not of excessive vigour or length.

SMALL FRUITS.—All plantations of Currants, Gooseberries, and Raspberries should be cleared of all rubbish and the ground "lightly" forked. In doing this keep a sharp watch for Blackbirds, that must be dug out entirely, even if a few roots of the bushes have to be disturbed in doing it. So far, I am pleased to note that but little harm has been done by the sparrows this spring; sometimes this bird is troublesome in destroying the buds, but sparrows also clear off some of the insect pests.

FRUITS UNDER GLASS

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Eccle Hall, Newcastle, Staffordshire.

OUTSIDE VINE BORDERS.—Long litter placed on the border for protection, together with about 2 inches of the surface soil, should be raked off. The roots are getting active and they will be encouraged to grow near the surface by applying a top dressing of fine material. Place a light dressing of short manure over the fresh soil and, should wet weather continue, galvanised iron sheets, placed with a slight tilt, will afford protection from excessive rains, but the protection should be removed directly the weather is fine again. For the present it is not advisable to give vines fed by less a heavy dressing of farmyard manure. This best applied directly after the thinning of the bunches, and even then the borders should be protected during very wet weather.

EARLY PEACHES AND NECTARINES.—Watch the trees very carefully on which the fruit is set and swelling for aphis, and at the first signs of the pest take preventive measures, or the earliest growths will be ruined. If black fly once gets established around the base of the young shoots, one fumigation has hardly sufficient effect to destroy the insects, and a second fumigation is necessary, followed by a vigorous syringing. Disbud the young shoots freely; usually too many of the young growths of Peach and Nectarine trees are allowed to remain, with the result that the wood fails to ripen. No hard and fast rule can be laid down, but two, or at the most three, shoots are quite enough for furnishing the succeeding year's fruit-bearing wood. If too many shoots are left they will grow weak, the foliage thin, and the fruit, for want of sun and air, will be poor and flavourless. A good method is to allow one shoot at the end, one in the centre, and another at the base, on the upper side if possible, of every fruit-bearing shoot trained in. All the intermediate growths should then be removed. It is advisable to remove even the centre shoot should it interfere with the training in of the growth at the base, which is, of course, the fruiting shoot for next year. By tying the shoots close to the base and bringing them nearly flat against the trees, unsightly bends will be prevented. The thinning of the fruits, as with the shoots, is best done by degrees, removing the smallest and worst placed specimens. Fruits pointing upwards to the sun are the best situated, and may be left until the final thinning is done at the stoning period. The borders may require water, which should be supplied liberally in a tepid state.

LATE PEACHES AND NECTARINES.—The latest Peach and Nectarine houses should be freely ventilated during mild weather. The trees cannot be retarded much longer, as the buds are almost bursting into flower. At the following stage a little fire-heat should be used to keep the blossom dry. Sharp frosts on a few days made it necessary to open the valves a little at night, for it is not advisable to allow the temperature to fall much below 40°; still, it should not exceed that degree.

THE ORCHID HOUSES

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

MASDEVALLIA.—Plants of strong-growing Masdevallias, such as M. Harryana, M. ignea, M. Veitchiana and M. Chelsoni that were not repotted in the autumn may be attended to now. Good specimens may be shifted into larger pots, doing this do not disturb the roots more than is necessary. Others that have overgrown their receptacles and have become bare towards their centres may be broken up, and, after cutting away all decayed parts, be potted in the small pots, or several pieces may be placed together in the same receptacle to form neat specimens. The pots or pans should be about three parts filled with drainage materials, and on top of the drainage should be placed a few pieces of Sphagnum moss. The compost should consist of a mixture of good fibrous peat and a little Sphagnum moss, and loam mould with a sufficient quantity of crushed crocks and silver sand to ensure porosity. In repotting, do not press the material too firmly about the roots. These plants do not like much root disturbance, and should be repotted only when the roots have filled the pots. The Orchid must not be shaded more than is necessary. As soon as the plants in the intermediate house, but during the summer the temperature of the cool house is most suitable to its requirements. Masdevallias of the Chimæra section, such as M. Bella, M. Wallisii, M. Candida, M. Backhouseana and M. Harryana should, if necessary, be potted "additional" [illegible] These plants are best grown in Teak wood baskets, and, as the flowers are produced on descending stems, crocks should not be used for drainage. A layer of Fern rhizomes laid over the bottom half serves the purpose of drainage well. The compost may consist of equal portions of Osmunda or A 1 fibre and Sphagnum moss, chopped rather finely. For a few weeks after root disturbance little direct watering will be needed, but the surroundings must be kept moist. After the plants become well rooted healthy specimens may be soaked two or three times a week, and sprayed overhead on frequent occasions to ward off attacks of small thrips and red spider.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

TREE CARNATIONS.—Water Tree Carnations in flower rather more liberally than heretofore, and, to aid the development of good blooms, sprinkle a little concentrated fertiliser over the surface of the soil about once a week. The growths will need constant attention in tying to keep them upright. Some of the more promising of the old plants may be shifted into larger pots. Plants which were treated in this way here last year are still producing good flowers. It is important, however, that such plants be kept perfectly free from insect pests and rust disease. Regular sprayings with a suitable specific will keep the plants clean. Stop the growth of young plants as they become large enough, and support them to a neat stake. Souvenir de la Malmaison Carnations are growing freely, and if they are not already efficiently staked this should be done at once. Water must still be afforded with extra care till the pots are full of roots, and stimulants given sparingly. Houses containing Carnations should be lightly fumigated about once a fortnight as a precaution against aphis.

CANNA.—The old roots of Cannas may be shaken free of the old soil and repotted. Use rich compost and pot firmly. Choice varieties may, if necessary, be increased by dividing the roots and potting each portion singly in small pots. For plants for ordinary decorative purposes pots 6 inches or 7 inches in diameter are large enough for a flowering size.

COLEUS THYRSOIDEUS.—Plants of Coleus thyrsoideus have finished flowering, and may be cut back and placed in a moist, warm house to produce cuttings. A few of the best plants may be shaken out and repotted into pots one size larger than the old ones. Such plants will make specimens suitable for grouping in a large conservatory. A few cuttings struck in May or June will provide useful plants for flowering in small pots. This Coleus may also be raised from seed sown at the present time.

BOUVARDIA.—It is time to attend to the propagation of this useful plant. The easiest method is to shake out the roots, cut them into small portions, and lay them in pans of fine sand. Well water the soil and place the pans in a warm house.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

EDGINGS OF PATHS.—Now is the proper time to lay grass verges, to straighten parts which have got out of line and form those which are dead. Where the path to be relaid is narrow, as it better to bring forward a little of the grass and to fill in the portion of the former than to put a narrow path as is the path which is subject to wear. As the advantage from turning the grass forward is that the narrow part bared may be filled in by means of seeds where good turf cannot be had. It detracts considerably from the neat effect of edgings when portions of the lawn near them get out of the general level, either too high or too low. In the former case, the turf should be slit with a spade cross-wise to the walk and then beaten and the edge straightened. In the latter, it must be turned back and enough soil introduced to bring it up to the level.

LARKSPURS.—Stock-flowered and Emperor strains of Larkspurs are the two best suited for garden decoration. The former requires so much attention in staking and tying that I have not grown it since 1914. The other type requires no stakes. The present is a suitable time to sow the seed of both kinds. My plan has been to sow thinly in cutting boxes, germinate the seeds in a cool structure, and transplant the seedlings from the boxes to the beds when they attain a height not exceeding 1 inch. Plants older and stronger than that are apt to die in numbers, while small plants seldom go off, and in the end the smaller plants make quite as large and as fine material as those produced with the expenditure of greater labour.

VIOLAS.—Viola plants should be possessed long ago with an abundance of roots and, particularly if the space they occupy is required for other plants or crops, they may be transferred to the quarters they are to fill through out the season as soon as the weather and soil are suitable for their removal. Varieties of V. gracilis may be planted out at the same time, and any other hardy plant, such as Nepeta Mussinii, Anthemis tinctoria, and Double Camomile, which have been rooted along with them.

DAFFODILS.—Before Daffodils make further progress any weeds that have appeared since the beds were attended to in autumn should be removed and the interspace Dutch hoed. A slight dressing of superphosphate scattered evenly over bare spaces before the hoe is used will be of great advantage, not only to the flowers, but also to the flower stalks, causing them to lengthen, and to the leaves, which it broadens and deepens in colour, with the result that a better quality of bulb is produced for next year's flowering. Narcissi of the Poeticus section and a few other late kinds should be left in the meantime if the blades have not yet broken through the ground.

EDITORIAL NOTICE.

Editors and Publisher. — *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. — *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. — *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENTS FOR MARCH.

TUESDAY, MARCH 5—
Scottish Hort. Asso. meet.
THURSDAY, MARCH 7—
Manchester Orchid Soc. meet
TUESDAY MARCH 12—
Roy. Hort. Soc.'s Comms. meet.
THURSDAY, MARCH 21—
Manchester and N. of England Orchid. Soc. meet
TUESDAY, MARCH 26—
Roy. Hort. Soc.'s Comms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.8

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, February 28, 10 a.m.: Bar. 29.6, temp. 42.5°. Weather—Bright sunshine.

Commercial Fruit-Growing.

For many years there has been a certain measure of antagonism, or at least of disunion, not only between individual fruit-growers, but between the different fruit-growing districts. As a result, commercial fruit growing has been disregarded as an industry, and the general public have formed the idea that the British fruit-grower is backward as compared with his Colonial and American confrère.

In the decade prior to the war commercial fruit-growing in the British Isles made progress by leaps and bounds. Many new plantations were laid out, worthless varieties were top-grafted, up-to-date spraying became a matter of usual routine, and growers concentrated on producing a large bulk of produce of only a few selected varieties.

With this new era local prejudice was gradually being cast aside, but the advent of the war stopped further progress for the moment.

During the first two years of the war fruit-growers found themselves in a very difficult position, their labour went into the Army and munition works, their produce was looked upon as a luxury and not a necessity, and the increased cost of production caused profits to diminish.

Times have changed, however: fruit may still be regarded by some as a luxury, but everybody agrees that when manufactured into jam it is a valuable food. Enormous quantities of jam have been used by the Army and at home, and with the supplies of butter and margarine becoming short, jam must make good the deficit.

The idea was recently conceived that the ancient Guilds in the City of London should play a leading part in the policy of reconstruction after the war. With this in view the Worshipful Company of Fruiterers, acting in conjunction with the National Fruit Growers' Federation, convened a conference, which was held in the Council Chamber at the Guildhall on Friday, February 22. At this conference members of the Fruiterers' Company and representatives of the various Fruit Growers' Associations in the country discussed and passed a number of important resolutions with a view to placing their industry on a sound foundation.

A luncheon, given by the Worshipful Company of Fruiterers, took place later at the Mansion House, by kind permission of the Lord Mayor.

The President of the Board of Agriculture, responding to the toast of "Fruit Growing," in a sympathetic speech urged the necessity for each industry in the country to organise itself and to prepare a constructive policy to be put into operation at the termination of the war.

In this connection Mr. Prothero mentioned that a Fruit Section had recently been formed in the Food Production Department of the Board of Agriculture, which, by working in co-operation with an Advisory Committee of Fruit Growers, would be a very valuable asset to forward this movement.

There are very many directions in which commercial fruit growers have leeway to make up. The inauguration of a campaign to induce growers to top-graft their useless varieties of Apples with sound varieties of sterling merit, such as Bramley's Seedling or Newton Wonder, would produce beneficial results in a short while, and will serve as an illustration of one of the lines along which progress is required.

To illustrate the point further, it does not pay commercially to grow Peasgood's Nonesuch, because it crops poorly, and is very subject to canker; Devonshire Quarrenden, because it cankers and scabs badly, Ecklinville Seedling, Potts' Seedling, and Dumelow's Seedling all suffer badly from scab; Yellow Ingestre and Northern Greening are too small for commercial use.

By heading these trees back and top-grafting them with the strong growing varieties previously mentioned, liability to disease is removed, and in four or five years large crops of excellent quality will be obtained. At the same time, the British fruit trade benefits not only by the increase in the bulk of these varieties, but also by the removal from the markets of small and diseased samples.

There are many other ways in which immediate progress can be made, but fruit growers must remember that they have been given a golden opportunity in which to reorganise their industry and make it both active and progressive. If they allow this opportunity to pass British fruit growing will not hold its own after the war. By their co-operation and enterprise the growers themselves, with the help of the Government, can secure for their industry the great position which it deserves.

THE FLOWERING OF THE ALMOND.—The forwardness of the present season is exemplified by an Almond tree growing at Wandsworth, near the Common, about five miles from the centre of London. This tree is now (February 23) in bloom, exactly two months earlier than last year, when the flowers first appeared on April 23. Previous to last year the flowering dates, reckoned backwards, were February 18, March 9, March 2, January 25, February 24, March 11, March 12, April 1, March 23, March 20, February 28, March 7, March 21. It will be seen by this record that the present date of flowering is the earliest but two.

THE LATE W. T. WARE.—Mr. WALTER THOMAS WARE, of Inglescombe, near Bath, who died on December 16, has left a fortune of the value of £137,092, the net personalty being £119,828. The testator bequeathed £250 each to the Gardeners' Benevolent Institution and the Royal Gardeners' Orphan Fund, and legacies to servants and other persons in his employment.

APICULTURE IN BRITISH EAST AFRICA.—The gathering of beeswax in the East Africa Protectorate is almost entirely in the hands of the natives, who obtain the product from wild hives in the country, remarks the *Journal of the Royal Society of Arts*. Very little scientific apiculture is practised, and that only by the European settlers in the highlands. Notwithstanding the present small production of honey and beeswax, the higher altitudes of the Colony are peculiarly well adapted to apiculture. Clover is an abundant crop, and other flowers are plentiful. There are two rainy seasons, no winters, and so far no serious bee diseases have developed. The Government is giving every encouragement to the industry, and the active interest of the settlers is being aroused to the opportunity. During the fiscal year ended March 31, 1915, the total export of beeswax amounted to 1,563 cwt., valued at £10,000. For export, the product is packed in bags containing 5 frasilas (180 lb.). There is no export duty.

SUNFLOWER SEEDS AS FOOD FOR POULTRY.—The seeds of the giant strains of Sunflowers are rich in oil, and are a valuable food for poultry. The only seed available in quantity is the American Giant strain. Seed may be obtained from leading retail seedsmen at a price which should not exceed 3d. per oz., 9d. per 4 oz., or 1s. 3d. per 8 oz. One ounce is sufficient for 8 rods, and 1½ lb. will plant an acre. The Food Controller will be prepared to purchase ripened seed in quantities of ½ cwt. and upwards, at a price to be arranged later. The yield, which depends on the season, should be at the rate of not less than 12 cwt. per acre. It is important that only vacant land be used; this culture is not intended to interfere with the planting of food or forage crops already arranged for.

WAR ITEM. We regret to hear of the death in action of Lieut. J. SALSBURY SMITH, son of Mr. J. SMITH, managing director of the firm of JAMES SMITH AND SONS, nurserymen, of Darley Dale, Matlock. Lieut. SMITH was only nineteen years of age, but was a youth of great promise, especially in scientific pursuits. He had only been at the front six weeks when he was reported missing, and later the news of his death

and burial was sent by the German military authorities.

LOCAL SOCIETIES.—Councillor R. A. THORPE, J.P., presided at the lecture delivered by Mr. W. F. GILES, of Messrs SUTTON AND SONS, Reading, to members of the Watford Horticultural Society on Wednesday evening, February 13, the subject being "Serviceable Vegetables and How to Grow Them." The attendance was good, and the lecturer's remarks were followed with keen interest.

PRIMULA MALACOIDES ALBA PLENA.—A group of this semi-double variety of Primula malacoides (see fig. 41), shown at the R.H.S. meeting on the 12th ult. by Messrs W. AND J. BROWN, was one of the most attractive exhibits in the hall. The flowers, which are produced in profusion, give the effect of being white, but on closer examination some of the petals display faint traces of colour, and there is a little yellow in the eye. The foliage is almost as attractive as the flowers, being of a delicate pale green, of Fern-like form. The plant makes a charming subject for the decoration of the conservatory and greenhouse in winter and spring, and is easy to cultivate. We are indebted for the illustration to Messrs. HURST AND SON, who inform us that they will distribute seed to the trade next autumn.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

APPLES RIVAL AND BARNACK BEAUTY (see p. 54).—Rival is a free growing variety. The fruits are of handsome appearance, of good flavour, and, for market purposes, of a shape which packs most attractively, especially where the 40 lbs. case is used. Last season bushel boxes of Rival from this district realised 27s. 6d. each in the Dublin market. This variety, in one part of the kitchen garden here, is inclined to canker a little, but the trees are rapidly growing out of the disease, whereas those in another part of the garden and in the orchard are quite free from canker. It is probably a question of soil or drainage, and I find that the best method of dealing with the complaint is to cut the cankered part clean out. I find that subsequent dressing of the wound is not necessary, as it is astonishing how quickly the damaged part heals and new bark forms around a branch when it is left to nature. I have never seen scab on my trees in the garden, but the fruits on the orchard trees were slightly affected by this fungus last season, and this in a year when varieties subject to scab, such as Bismarck and Cox's Orange Pippin, were unusually free from the complaint. With regard to Barnack Beauty, young orchard trees of this variety, seven years planted, are growing strongly, and making regular and shapely heads. The great value of this variety is the late-keeping qualities of the fruits, and as a market variety, in its attractive colour and appearance. The fruits keep well until mid-April, and perhaps later; ours are usually finished at about this date. I find that, like Allington Pippin, the tree bears heavily in alternate seasons, but no doubt this characteristic could be modified by judicious thinning when a heavy crop of fruit has set. The fruit is not of the first quality as regards flavour, but is probably equal in this respect to the majority of Apples on the market in April. The tree is not quite free from canker here, but its slight tendency to this disease is more than counterbalanced by its strength of growth. The fruit, which is bright and well coloured, does not suffer at all from scab.—*T. E. Tomalin, Beesborough, Piltown, Kilkenny.*

IRIS STYLOSA (see p. 30).—With me, Iris stylosa opened its first flowers in November at the foot of a south wall, and the plants have continued in bloom ever since. This Iris is undoubtedly one of the most useful of hardy plants, as the flowers appear when but little else is in bloom out of doors. The blossoms last fresh for a long time in water, provided the stalks are cut at an early stage, as all flowers should be where they are required for indoor decoration.—*E. Molyneux, The Farm, Sherborne Park, Hampshire.*

UNDESIRABLE APPLES (see p. 66).—Owing to the variations of Apples in certain localities many fruit growers will differ from *E. M.* as to "undesirable varieties." Schoolmaster is unequalled quality for cooking to those who appreciate a tart Apple. It combines the acidity of Dumelow's Seedling (Wellington) with a rich flavour, and is at its best condition during January, February and March. Barnack Beauty is a profuse cropper, of beautiful appearance and fairly good in flavour; the fruits are at their best in April. Bedfordshire Foundling retains its briskness long after Bloodnam Pippin has become insipid. Hawthornden has many conpects in November, but as a certain cropper for the cottager's garden; whilst Nanny is of delightful aroma when well coloured in October. Gravenstein has the remarkable property of firm flesh in the beginning of October, and pleasant mellowness at the beginning of February.—*Will Taylor, Hampton, Middlesex.*

HIPPEASTRUM ACRAMANNII (see p. 63).—I have a bulb of "Amaryllis" Acramannii pulcherrima. It was sent me by my father, who brought the plant from The Lawn, Swindon, Wiltshire, into Hampshire, in about 1872. No doubt the original bulbs were procured from Bristol or Bath, as my father was often an exhibitor at the West of England shows in those days. I have had my bulb twelve years, probably more, and as yet it has produced no offset. It flowers every season [illegible] the flower spike is about 3 inches [illegible].—*H. Stockland, Abbeyan Hall Gardens, Mr. Derbyshire.*

MEALY BUG ON HIPPEASTRUMS.—In the article on Hippeastrums, p. 65, the writer refers to trouble caused by mealy bugs if they obtain a lodgment on the plants. Some years ago the late Herr Max Leichtlin, of Baden Baden, wrote at this subject in a contemporary journal as follows: "There is a very simple way of getting the plants at least all Amaryllideae perfectly clean by planting the bulbs for a year or two deeper than usual, that is to say, so deep that the two joints from which the green shoots spring are just level with the soil. The creature dislikes moisture, and soon lodges between the leaves; by searching two or three times carefully it can be exterminated. We grow Amaryllids, for convenience' sake, above the soil, but it is unnatural and likely to promote the existence of insects." I have never had an opportunity to carry out this treatment, but the experiment seems to me well worth trying.—*W. T.*

PE-TSAI.—*J. E.*'s remarks on p. 38 are very interesting. I have grown Pe-Tsai for many years, and my experience agrees with that of writers and friends in that it invariably bolts if sown so early, yet he records getting very fair heads from May sowing. In China it is apparently available all through the winter. Where is *J. E.*'s garden? Has he really got Pe-Tsai or is it Pak-Choi or some other kind?

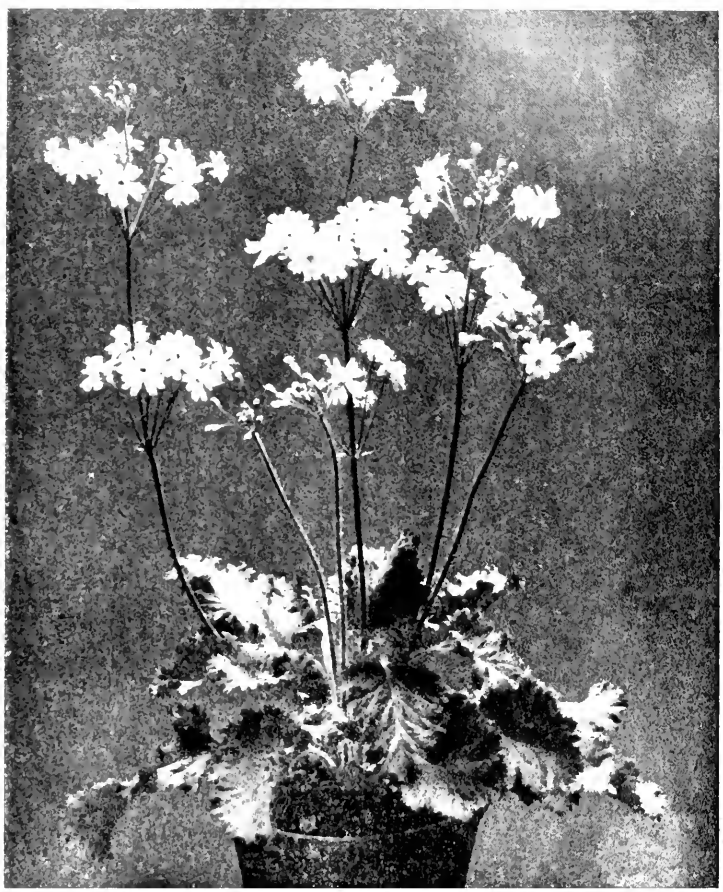

FIG. 41.—PRIMULA MALACOIDES ALBA PLENA.

The allusion to a Cabbagy flavour is against its being Pe Tsai. Cooked like English Cabbage it would find no more favour with me than that article. Pe Tsai forms a good salad eaten raw. *H. E. D.*

THE EFFECT OF ONE PLANT ON ANOTHER.—On taking charge of these gardens some nine years ago, I found an orchard of young standard fruit trees which had been planted on about ¾ acre of a field in the west of the gardens. The grass had been allowed to grow close up to the trees, and was not even mown, with the result that all but three of the trees had lost their heads entirely. On examining them I found that they had been cutted low down near the ground, and that the stems were still green, although their tops were dead. I had the grass cleared away for a distance of 6 feet, and gave the roots of each tree a dressing of basic slag and one barrow load of farmyard manure in November. The next year the stems sprouted at from 2 to 3 feet from the ground, the old tops were cut down to just above the new growths, and the trees treated as maidens and trained into shape. The trees have received the same treatment each autumn since, and the newly formed heads are now 9 to 10 feet through, clean and very healthy. Last season each tree had a crop of from two to three bushels of first-class fruit. The three trees which had not lost their heads were lifted and planted in a row by themselves, and treated similarly to the others, with the same good results. The varieties include King of the Pippins, Bismarck, Blenheim Pippin, Dr. Harvey, Ribston Pippin, Warner's King, Cox's Orange Pippin, Lord Derby, Gascoyne's Scarlet, Bramley's Seedling, and Lane's Prince Albert. After the first season the whole of the grass was trenched and the ground cropped with vegetables, and this treatment is still followed, with the result that we get first class fruits and vegetables. Another orchard of the same size in the same field of established trees, some 50 or 60 years old, had been neglected, and the grass allowed to grow. These trees were covered with lichen and growth was stunted. They gave a plentiful crop of worthless fruit. The whole orchard was cleared of grass, the latter burnt and the ashes spread over and dug in the soil. The roots afterwards received a dressing of basic slag, and the soil was hoed and kept clean during the following season. The trees have regained their vigour in leaf and growth, and the fruit now is all that could be desired. I was told by an old hand on the place that this orchard, under the care of a former gardener, had produced good fruit when annually dug and kept clean, but since the grass was allowed to grow the trees had fallen back year by year into the state that I found them. Is not all this conclusive proof of the poisonous effect of the grass to the roots of fruit trees? This should help to remove any doubt that the cause of degeneration in such fruit trees is toxic and not physical. *C. Capp, Old Abbey Gardens, Lowestoft, Suffolk.*

"SPECIALLY USEFUL ROSES."—I always read *White Rose's* notes with pleasure, and generally with instruction, but his remarks under the above heading on p. 64, are open, however, to an objection which I have made before in your columns. It is quite useless to tell us which are the twelve best Roses without telling us under what conditions of soil, aspect and situation the decision has been arrived at. In naming the twelve best Roses *White Rose* says "the first half-dozen will require little consideration," and proceeds to name six, among them Madame Ravary and Madame Leon Pain. I have grown the former both in my Kent and in my Hampshire gardens ever since it was introduced, and I have never had a single bloom on it worth looking at, nor will it grow with me. I think it has now dwindled away in Kent to a couple of weedy specimens. Madame Leon Pain has never been a success with me. Of the second half dozen, perhaps I do not know enough of the variety Ophelia to say much; Gruss an Teplitz grows fairly well, but produces paltry blooms; Papa Gontier produces some good flowers, but gives out after a couple of years. Now I am not saying for a moment that these are not capital Roses in many gardens, but for me they are no use at all. The soil of my Kent garden is a strong, holding loam, partly over clay, partly over sandrock, and it is well drained, as the ground slopes sharply to the south; we are about 400 feet above sea level. My Hampshire garden had a like soil over a thin bed of clay with gravel beneath, but was only about 40-50 feet above sea level. Now the four best Roses I have ever grown (I am not dogmatising, only giving my personal experience) are Antoine Rivoire, Caroline Testout, Hugh Dickson and Lady Hillingdon, and far and away the best of the four is the first-named Antoine Rivoire. The plant grows well, is in flower all the season, the blooms are always of good shape, and have thick, shell like petals that are unharmed by sun or rain. My old friend Mr. Edward Mawley used to declare to give the best twelve Roses for any garden except his own. My experience, after forty years, is, that it is impossible to name the best twelve or twenty-five Roses for any garden out of one's own district. *B. P. S.*

FIG. 42.—THE STORING OF APPLES. THE INTERIOR OF THE FRUIT ROOM AT ALDENHAM IN FEBRUARY.

NOTES FROM AMERICA.

THE CUT-FLOWER INDUSTRY.

WHILE the war has naturally made some difference in the volume of sales of pot plants and cut flowers in the United States, the reports on Christmas business go to show that it was very large, and in some sections broke all records. To counteract in some measure the outbursts against the culture of flowers in times of war, the Society of American Florists has inaugurated a publicity campaign, and will spend $50,000 this year, chiefly in full-page advertisements in magazines of the largest circulation, advocating the buying of flowers.

We are having a very severe winter, the ground having been frostbound since November 22. The opening week of the New Year broke all records for intensity of cold, the maximum shade temperature in Boston not rising over zero for two or three successive days. To make matters worse for everyone we were suffering from an acute shortage of fuel, and the intense cold did great damage, and caused much suffering. Many commercial and private ranges of greenhouses are closed wholly or in part, owing to an inability to secure coal. Wood is being largely used as the substitute, and while coal prices are held down by the Government, the wood has doubled in value.

Efforts to induce the fuel administrators to refuse coal to florists and others owning greenhouses on the ground that they are non-essential and luxuries, have been unsuccessful so far, and we trust will remain so. Many greenhouses are being devoted to vegetables where formerly flowers were grown, and their number will increase if the war continues.

The various national societies continue their activities in a slightly modified manner, and all have had good exhibitions, with the exception of the Massachusetts Horticultural Society, which lately voted to eliminate money prizes from its 1918 schedule; all other societies are proceeding as in former years. Profits on exhibitions, where admission charges are made, are being mainly devoted to the Red Cross.

Food production holds the centre of the stage here as in Great Britain. Last year saw a tremendous boom in small gardens, or "war gardens," as they are termed here. In spite of late beginnings, unfavourable weather, and some other discouragements, an estimated yield of $350,000,000 worth of vegetables was produced in these new gardens in 1917, and we hope to double these figures during the present year. One great result of this war will be that we shall have far more tillers of the soil than ever before, and horticulture will, as a result, receive a great stimulus. *W. N. Craig, Brookline, Mass., U.S.A.*

THE STORING OF APPLES.

I was much interested to read the note by *Puzzled* in your issue of Jan. 12, p. 19. The opinions of Mr. Beckett and Mr. James Hudson are certainly entitled to the highest respect, but *Puzzled* will be quite safe in following the advice given by Mr. Beckett on p. 8. It may interest some of your readers to know that when picking the Apples here we take clean flour or sugar barrels, each holding about two and a-half bushels, into the orchard and place the Apples in them as they are picked. No lining of any sort is used in the barrels, but each Apple is inspected to see that it is perfectly sound, and care is taken not to bruise it. When the barrel is full it is placed in a moist cellar with a soil floor, where the temperature does not fall below 35°, and the Apples keep perfectly, retaining their flavour and firmness. Having tried both methods extensively, that of laying them out singly and piling the fruits thickly together, I have no hesitation in saying I consider the latter method much the better. *Arthur E. Thatcher, Mount Desert Nurseries, Bar Harbor, Maine, U.S.A.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 26.—There was only a small exhibition on the occasion of the fortnightly meeting in the Drill Hall, Buckingham Gate, on Tuesday last. The Narcissus Committee held its first meeting for the year, and the largest and most important exhibit was a group of Tulips, for which the Committee awarded a Silver-gilt Flora Medal.

Orchids again formed an attractive feature of the exhibition, and five novelties received awards from the Orchid Committee.

Several novelties were submitted to the Floral Committee, and Awards of Merit were recommended for two new Saxifragas. Hardy flowers and Alpines were contributed by a number of growers, but the displays were not comparable to the exhibits of spring flowers which were formerly made. Saxifragas formed a feature of most of these collections and specially good plants were staged by Messrs. R. TUCKER AND SONS, whose group contained Saxifraga Obristii (white), S. macedonica, S. Griesbachii, S. oppositifolia Latina, S. Burseriana minor, and the beautiful yellow Faldonside. T. TEMPLE WEST, Esq., Gatton Point, Redhill, showed a somewhat similar exhibit, the two best Saxifragas of which were S. Irvingii and S. Burseriana crenata, the varietal name being derived from the irregular notchings in the petals. Of even more outstanding merit than the Saxifragas, however, were the plants of Lycopodium clavatum and L. dendroideum, for each of which a Cultural Commendation was awarded. Mr. G. REUTHE's exhibit of sheets and Alpines included the delightful, blue-flowered Crocus Aucheri, and a magnificent specimen of Shortia uniflora grandiflora. Messrs. H. J. CHAPMAN, Ltd., showed a number of Daffodils, hybrid Freesias and Irises of the reticulata section. The Freesias included a new variety named Opal, delicately shaded with rosy lavender. The Committee expressed a wish to see this variety on a future occasion. P. L. MOND, Esq., Sevenoaks (gr. Mr. C. Hall), showed two large groups of flowering plants, one entirely composed of Primula malacoides, the other of Schizanthuses with a row of Epacrises along the front. Messrs. ALLWOOD, Bros. again contributed some fine Carnations of the perpetual flowering type, and Messrs. H. B. MAY AND SONS' group of beautiful Ferns, interspersed with flowering plants, was well worthy of notice.

The Fruit and Vegetable Committee found nothing for their consideration.

At the three o'clock meeting of the Fellows, Mr. F. CHITTENDEN delivered an address on "The Relative Food Values of Garden Crops."

Floral Committee.

Present: Messrs. H. B. May (Chairman), W. J. Bean, R. C. Notcutt, S. Morris, G. Reuthe, H. Cowley, E. A. Bowles, J. Green, J. T. Bennett-Poë, J. Heal, W. P. Thomson, J. F. McLeod, A. G. Jackman, J. Hudson, T. W. Barr, T. Stevenson, C. R. Fielder, R. C. Reginald Neville, A. Turner, J. W. Moorman, C. Dixon, C. E. Shea, C. E. Pearson, E. H. Jenkins, W. B. Cranfield, and W. A. Bilney.

AWARDS OF MERIT.

Saxifraga kewensis rosea. — This dwarf Alpine Saxifrage belongs to the red-stemmed section, the spikes arising from a dense tussock of silvery-grey foliage. The flower-stems are about 2½ inches long, and bear small, pale pink, bell-shaped blossoms about half an inch wide across the mouth. The stems are arching, which gives a marked character to the variety. Shown by Mr. G. REUTHE.

Saxifraga Burseriana sulphurea. This is a hybrid between the rich yellow Faldonside variety and S. Burseriana. The flowers are pale sulphur yellow, about the same size as those of S. Burseriana major, but with the circular outline of Faldonside. The plant is very free in flowering, a specimen in a large 60-sized pot bearing 18 well-developed blooms. Raised by Mr. G. H. SIMPSON HAYWARD, Incomb Manor, Stow-on-the-Wold, and exhibited by Messrs. R. TUCKER AND SONS.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), William Bolton, R. Brooman-White, C. J. Lucas, Walter Cobb, W. H. White, Frederick J. Hanbury, J. E. Shill, J. Charlesworth, E. R. Ashton, T. Armstrong, Fred. Sander, Panl's Ralli, J. Wilson Potter and B. A. Rolfe.

AWARDS.

FIRST-CLASS CERTIFICATES.

Laelia Cattleya Schroderae (*L.-C. Bella alba* × *C. Maggie Raphael alba*), shown by Mr. J. E. SHILL, The Dell Gardens, Englefield Green.—A distinct hybrid of perfect shape; the broad sepals and petals are clear white and the well-rounded lip violet-crimson with a narrow silver-white margin and yellow lines and disc.

Odontoglossum "St. James' amabile" × "Amethyst", from Messrs. CHARLESWORTH AND CO., Haywards Heath.—A noble Odontoglossum, the fine plant bearing a strong spike of large, perfectly shaped flowers. The sepals and petals are violet-mauve with broad white margins and tips.

AWARDS OF MERIT.

Laelia Cattleya Beatrice var. Bryndir (*C. Schroderae* × *L.-C. callistoglossa*), from Dr. MORRIS LACROIX, Bryndir, Rochampton (Orchid grower Mrs. Robertson).—A distinct advance on the varieties previously shown. The sepals and petals are broadly rounded, and are of a rich blush-rose. The front of the lip is rich purple and crimson, and the side lobes are yellow.

Laelia Cattleya [illegible] "Ashtonii" (*L.-C. Dominiana* × *C. Mendelii*), from Messrs. J. OSBORN & MCBEAN, Cattleya Nurseries, Anerley. A pure white flower of perfect shape, much like the variety *L.-C. Dominiana alba*, but the plant is dwarfer and the flowers rather larger. A form with a purple stain at the tip of the side lobes.

Sophro-Laelia Cattleya "Hatch Hyatt" (*Sophro-Cattleya Hatch Hyatt* × *L.-C. Hatch Hyatt* × *S. grandiflora*), from Messrs. STUART LOW AND CO., Enfield Nurseries, Sussex. One of the most brilliant of dark scarlet hybrids, the colour being nearest to a dark Sophronitis grandiflora, but with a deeper red shade. The lip has yellow markings at the base.

PRELIMINARY COMMENDATIONS.

Acridovanda Mundyi (*Acridovanda* × *Vanda teres*) (see fig. 43), from Sir JEREMIAH COLMAN, Bart., Gatton Park, Surrey (gr. Mr. Colbert).—A specially interesting hybrid, as being the first cross between these two genera. The flower is fairly intermediate between the parents, *V. teres* showing plainly in the lip with its median isthmus and other characters. The sepals and petals are silver-white with a light rose shade. There were three plants, each about 6 inches in height and four years old.

Odontioda Juliet (*Oda. Bradshawiae* × *Odm. prometaneum*), from Messrs. CHARLESWORTH AND CO. The flowers are of fine form, reddish-mauve in colour, with slight rose markings.

Odontioda Armstrongii Orchidhurst variety (*Oda. Englsteadae* × *Odm. Armstrongiae*), from Messrs. ARMSTRONG AND BROWN, Tunbridge Wells.—The sepals and petals are broad and overlapping, deep rosy-mauve in colour, with a few white markings. The broad lip is white in front with rose spotting, and there is a large mauve blotch in front of the yellow crest.

GROUPS.

Messrs. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for a varied group containing many new and rare [illegible]. A piece of Sophro-Cattleya Atreus (*Sophro-Cattleya* × *C. Lawrenceana*) had the [illegible] shaped flowers, and is the best of that cross yet, as it does not show the rose tints of [illegible]. The group included a plant of *Cym.* (from Beryl (Lowianum × Pauwelsii) with [illegible] of flowers which have a chestnut-red [illegible] and *Cypripedium Mysem* (Mr. W. Myers' Fairieanum), with intensely dark [illegible] on the white ground of its dorsal sepal.

Messrs. CHARLESWORTH AND CO. were awarded a Silver Flora Medal for a select group of Odontoglossums, Odontiodas, and others. Among the novelties were hybrids was Odontonia Irene (Mrs. Warscewiczii × Odm. hastilabium), with dark purple sepals and petals and well-developed fringed white lip.

Messrs. SANDERS were awarded a Silver Banksian Medal for a group in which the best

FIG. 43.—ACRIDOVANDA MUNDYI. (See Award by the Orchid Committee.)

plants were the new Brasso-Cattleya Calypso, a very large flower of a clear blush-rose tint, the broad petals being arranged wing-like beside the very ample clear rose lip, which is crimped and fringed at the margin; and Cymbidium Elfin, a white flower of fine substance and with attractive purple markings on the front of the lip.

Messrs. HASSALL AND CO., Southgate, were awarded a Silver Banksian Medal for a good group of Cymbidiums, including forms of Sybil, Corona, Alexanderi, and Castor.

Messrs. STUART LOW AND CO. were awarded a Silver Banksian Medal for a group in which the scarlet Sophro-Laelio-Cattleyas and forms of Cattleya Trianae, including the fine varieties Mrs. De B. Crawshay and His Excellency, were prominent.

Sir JEREMIAH COLMAN, Bart., showed Dendrobium Queen of Gatton and pans of Sarcochilus Hartmannii and S. Fitzgeraldii, with eighteen spikes on each specimen.

J. BRIDSON SLATER, Esq., Upper Richmond Road, Putney, exhibited Odontioda Graireana var. May, with cinnabar-red flowers and pink labellums.

Dr. MIGUEL LACROZE staged Odontioda Ethel var. Bryndir (Oda. chelsiensis × Odm. percultum); the centres of the segments are spotted with orange-red.

Narcissus and Tulip Committee.

Present: Messrs. E. A. Bowles (in the chair), J. F. Bennett-Poe, W. B. Cranfield, G. Reuthe, W. Poupart, Geo. Monro, junr., Herbert Chapman, G. W. Leak, and C. H. Curtis (hon. sec.).

The brightness and freshness of early spring was imported to the meeting by exhibits of Daffodils and Tulips shown by Messrs. H. CHAPMAN, Ltd., and Messrs. R. H. BATH, LTD. The former showed numerous good seedling Daffodils derived from King Alfred and a sturdy variety named The Parson, with white perianth and creamy trumpet. Messrs. BATH had a splendid display of Daffodils and Tulips grown in bowls containing fibre; the exhibit was well arranged on a low staging, and bowls of Polyanthus, Narcissi, together with pots of Enchantress, Van der Neer, Yellow Prince and Prince of Austria Tulips were particularly good. (Silver-gilt Flora Medal.)

Mr. J. A. JARDINE, Wandsworth, showed boxes of small seedling Daffodils to illustrate his method of raising these bulbs.

Fruit and Vegetable Committee.

Present: Messrs. W. Poupart (in the chair), A. D. Tuckett, W. Bates, A. Bullock, Owen Thomas, E. Beckett, F. Jordan, Ed. Harris, A. R. Allan, E. A. Bunyard, G. P. Berry, and W. Wilks.

HORTICULTURAL CLUB.

ANNUAL MEETING.

FEBRUARY 26.—The annual meeting of the Horticultural Club took place on Tuesday, the 26th ult., the president, Sir Frank Crisp, Bart., in the chair. The attendance was small, and the hon. secretary, Mr. R. Hooper Pearson, was not able to be present, owing to indisposition. The hon. treasurer, Sir Harry J. Veitch, was also absent, in consequence of having to attend a meeting of the War Horticultural Relief Fund.

The minutes of the preceding annual meeting were read and adopted. The report of the Management Committee for 1917 was then read; we publish the following extracts:—

Towards the end of June, 1917, the Hotel Windsor was commandeered by the Government for official business, including the room which formed the headquarters of the Club. This unexpected event had the effect of disorganising the Club for the rest of the year. As the holiday season followed close upon the loss of the room, little could be done in regard to getting another one until September. From thence onwards enquiries were made at all sorts of places in the neighbourhood of Westminster, with a view to obtaining headquarters similar to those which the Club possessed at the Hotel Windsor. Eventually an agreement was arrived at under which the Horticultural Club agreed to accept the hospitality of the Farmers' Club for a period of six months, or, provided both parties are agreeable, until the termination of the war.

Regarding the personnel of the Club, there have been many losses owing to deaths. Among these may be mentioned Mr. William Marshall, an honorary member and one of the founders of the Club, and Mr. C. T. Druery a very old member of the Committee. Six new members have been elected.

The total number of members is now 193, showing a net loss of seven during the year.

The president, Sir Frank Crisp, read the Statement of Accounts, which had been sent by the treasurer, and proposed the adoption of the Report and Balance sheet, which was carried unanimously.

The members of the Management Committee were re-elected, and Mr. H. Somers Rivers appointed to the vacancy caused by the death of the late Mr. C. T. Druery.

It was decided to send expressions of sympathy in his illness and thanks for his services from the meeting to the secretary, Mr. R. Hooper Pearson, Sir Frank Crisp undertaking himself to send the message.

Mr. Geo. J. Ingram was elected auditor, to act with Mr. R. Pinches, in place of the late Mr. C. T. Druery.

Several members expressed the hope that the Committee would arrange occasional meetings of the Club, and 4 p.m. on the Tuesdays when the R.H.S. fortnightly meetings were being held was suggested as a suitable time and dates. The matter was left to the discretion of the secretary and Committee.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

FEBRUARY 11.—The monthly meeting of this Society was held in the R.H.S. Hall on the 11th inst., Mr. Arthur Bedford in the chair.

Two new members were elected. Two members were allowed to withdraw from their deposit accounts sums amounting to £23 2s. 6d.

The sum of £117 15s. 6d. was passed for payment to the nominees of two deceased members. The sick pay for the month was (ordinary) £31 3s., (State section) £28 3s. 4d., and maternity claims) £9.

The annual general meeting will be held at the R.H.S. Hall on the 11th inst.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 17.—*Committee present:* Messrs. R. Ashworth (in the chair), J. Evans, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, J. McNab, W. Shackleton, H. Thorp, and H. Arthur (secretary).

FIRST-CLASS CERTIFICATE.

Cypripedium Garland var. Lady Northbourne (*Hera* × *Lord Wolmer*), a round flower with white dorsal sepal, apple-green at the base, heavily blotched with purple-brown; the petals are 1¾ inch broad, have a green ground, and are blotched and veined with reddish-brown. From the Hon. ROBERT JAMES.

AWARDS OF MERIT.

Cypripedium Lord Wolmer var. Duke of Marlborough (*Euryades* × *Leeanum*), from the Hon. ROBERT JAMES

C. Diadem var Lady Beatty, from S. GRATRIX, Esq.

FEBRUARY 7.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. Cypher, A. G. Ellwood, A. Hanner, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, W. Shackleton, H. Thorp, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Odontoglossum Promerens var. Gratrixae, O. exultans var. Vulcan, O. Louise var. The Premier, O. Thwaitesiae var Rubellum (*Harryanum* × *Rossii rubescens*), and *Cypripedium Sir Wm. Chance West Point var.* (*Memoria Jerninghamiae* × *Thompsonianum*), from S. GRATRIX, Esq.

Odontoglossum Amillus (*Amethyst* × *illustrissimum*), and *Cypripedium Desdemona var rotundum* (*Alcibiades* × *Mrs. Carey Batten*), from Dr. CRAVEN MOORE.

Cypripedium Saladin (*Chapmanii* × *Olenus*), and *C. Thisbe*, from T. WORSLEY, Esq.

Odontoglossum crispum var. John Hartley (parentage unknown), from JOHN HARTLEY, Esq.

AWARDS OF MERIT.

Odontioda Schröderianum Ashlands var., *Odontoglossum Caroline* (*loochristense* × *Pescatorei*), and *O. Monte Video* (*Thompsonianum* × *Lambeauianum*), from R. ASHWORTH, Esq.

Cypripedium Vivian (*Wilson Potter* × *Euryades*), and *C. Clonis* (*Aeson giganteum* × *exul*), from T. WORSLEY, Esq.

Cypripedium Desdemona var. Conyngham, from Dr. CRAVEN MOORE.

Cattleya Monarch (*Trianae Royal Monarch* × *Empress Frederick*), from S. GRATRIX, Esq.

Brasso-Cattleya Enid (*C. Enid* × *B.-C. Leemanii*), from the EXORS. of the late JOHN LEEMAN, Esq.

AWARDS OF APPRECIATION—1ST CLASS.

Odontoglossum exultans (*excellens* × *crispum*), and *O. Orissa* (*ardentissimum* × *hylandianum*), from Messrs. ARMSTRONG AND BROWN.

GROUPS.

Large Silver Medals were awarded to R. ASHWORTH, Esq., Newchurch (gr. Mr. Davenport), and Messrs. CYPHER AND SONS, Cheltenham, for groups.

CROPS AND STOCK ON THE HOME FARM.

CABBAGE FOR CATTLE.

NEVER has the value of the Cabbage crop been better proved than during the present winter; 19° of frost did the plants no injury. Our cows were fed with them and Mangolds early in November, and have continued ever since to give satisfactory results, both in the quantity and quality of the milk produced. It is surprising what a large quantity of food an acre of Cabbages will supply.

The two forms of Drumhead—Early and Late—are all that are required, although several other sorts render good service. Greater breadths of this food should be grown throughout the country. Cabbages are useful as food for all kinds of stock, pigs, and poultry.

PIGS.

AT the present moment pigs appear to be under a cloud; whether they will survive the difficulty of finding food sufficient to maintain anything approaching their normal quantity during the next two years is a problem. All who have the smallest opportunity to keep them should do so. Prices are remarkably good for all classes, especially breeding stock and stores. Last week I saw a sow and three young ones nine weeks old sold for £28, and a barren sow, on the weight system, for a similar sum. Surely such prices should be encouraging to the pig-keeper!

When, however, we are told that pigs can be kept on grass with the addition of refuse, vegetables, etc., one is inclined to wonder if one's experience is of any value. I keep a number of breeding sows which give, as a rule, ten pigs each litter, two litters yearly, or certainly three in two years. Such stores at twelve weeks old will realise £2 each. Whether in the future this can be repeated is a question. My sows have a yard at night, with plenty of litter for warmth; the more they have the greater is the manure made; by day they run a small paddock, adjoining, where they eat grass, Cabbages, Mangold, Sugar Beet, and small and diseased Potatos, when there are any. In the evening they are given a small quantity of meal and water. Bran is the favourite food, but now quite unobtainable since 4 per cent. more flour is taken from the wheat for bread. The sows flourish well on such a ration. Exercise is a salient point in pig-keeping. With this there is seldom, if ever, cramp or stiff joints, or anything of a more serious character.

As the sows approach parturition they should be isolated, and after that event should be fed on more stimulating food, such as middlings and milk, if possible. When the young pigs are a month old they should be encouraged to drink milk and eat from a separate trough in an adjoining stye, to which they can easily gain access through a small hole in the partition.

No matter how good a mother to her young a sow is, the bulk of them have a strong tendency to gobble up all the food, leaving the young pigs destitute. It is wise to encourage the young pigs to eat meal and milk many times daily, a little at a time; they thrive all the better for any extra attention given them in this respect.

I hope that circumstances will be such that for the pigs in this minor way we shall be in a position to give this much food, because I fail to see how they are to be reared without the aid of some small quantity of meal.

POULTRY.

The poultry keeper is in a dilemma as to the necessary food for chickens and a small amount of Corn or meal for the laying stock. Much may be done to supplement the at one time general food of tail Corn and the various meals by the growing of green crops such as Cabbages, Mangolds, and Turnips. Mangolds, if given too freely raw, cause scour, but not when boiled. By slicing them they are more easily cooked, and with small Potatos, adding quite a small quantity of meal, a good food is provided.

In an ordinary farmyard, after thrashing ricks of any kind, hens find much food among the straw, and, indeed, for a long time afterwards, if the hulls and caving are carefully put into a heap and kept dry. A portion of the refuse food can be used daily, and it will afford the bird exercise in scratching, thus encouraging egg production. Grain of any kind that is fit for human food must not be used for poultry. Where there is considerable scope for ranging, especially in woods, hens do remarkably well, and let us hope that, by chicken-rearing time—March and April—food of some kind will be more plentiful. *E. Molyneux.*

SEED OATS.

THE Food Production Department is prepared to supply farmers direct with not less than 25 quarters of one variety of seed Oats. The varieties offered are (1) Manx White Oats of the "Abundance" type, f.o.r. Liverpool in returnable sacks, at 65s. per quarter of 336 lbs.; (2) Black Tartarian Oats, recleaned, at 65s. per quarter of 336 lbs., in non-returnable bags, f.o.r. Bristol; (3) Black Tartarian Oats, in non-returnable bags, f.o.r. Bristol Channel ports, Liverpool, Manchester, or Fleetwood, at 62s. per quarter of 336 lbs. The Department can also supply farmers with Scottish White Seed Oats of such varieties as "Abundance," "Leader," "Yieldbest," "Victory," "Record," "Banner," and "Waverley," at prices varying from 58s. to 65s., f.o.r. Scotland in hired railway sacks. In the case of these Scottish Oats farmers must be prepared to take a complete parcel, as the Department is not prepared to divide it. Particulars of the parcels available may be obtained on application to the Food Production Department, 72, Victoria Street, S.W. 1. In view of the scarcity of certain varieties of seed Oats in England, and of the increasing difficulties of transport, it is most important that provision should be made for obtaining seed Oats immediately. Samples of Manx Oats and of Irish Black Tartarian Oats may be obtained on application to the Oats Distribution Committee of the Liverpool Corn Trade Association, 9, Brunswick Street, Liverpool. Samples of Irish re-cleaned Black Oats may be obtained on application to the Oats Distribution Committee of the Bristol Channel and West of England Corn Trade Association, 56, Queen Square, Bristol.

LAW NOTE.

DAMAGE BY FALLING TREES.

THE Scottish Court of Appeal has given a verdict in a case concerning the liability for damage caused to a neighbour by the fall of a tree growing in the garden of an adjoining house. Inside the defendant's garden, close by the boundary wall, was a row of Poplars. The trees were of considerable dimensions, being 8 feet in girth near the base. The trees were all pollarded, and overhung the neighbour's buildings. First one of them was uprooted by the wind, and did some damage, but no complaint was made about the danger. There was no evidence that the tree which fell first had been decayed. Three months after the fall of the first tree an exceptional gale broke off the top part of another tree, which fell on the adjoining stable, and did damage estimated at £23. The neighbour sued in the County Court and obtained judgment. An appeal was taken by the tenant to a Divisional Court, but the two judges comprising that Court took opposite sides. The case was then carried to the Court of Appeal, and defendant was held not liable. The legal question was: Was there negligence? The fall of the first tree did not show danger, for it was overturned, not broken across like the second. The state of the wood of the first tree might have been important, but it was not proved. As to the pollarding, and the argument that that made the tree top-heavy, it was admitted that there might have been some inference of that kind if an ordinary wind had brought about the breakage, but it was proved to have been uprooted by quite an exceptional gale.

MARKETS.

COVENT GARDEN, February 27.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS.

REMARKS. Large supplies of cut flowers are arriving this week. Difficulties are the most plentiful, large quantities of the chrysanthemums being sent from Cornwall, Scilly, and Guernsey. Homegrown varieties consist of Emperor, Empress, Golden Spur, Princess, Sir Watkin, and Victoria, these are now at their best. Roses are now becoming more plentiful; Richmond and Sunburst are the best so far offered. Prices remain firm. Tulips are more plentiful and the quality is much better. There are some fine blooms of mauve, pink, and bronze Darwins. Liliums and Richardias are not so plentiful this week, and prices are firmer. Supplies of Lily of the Valley are sufficient for the demand. Violets (Princess of Wales) are reaching the market in excellent condition, and the supplies are equal to requirements. The majority of the Violets sent from the South of France are unsaleable when they arrive here. Other flowers are reaching the market in fair condition, and the supplies are a trifle larger this week. The chief supplies consist of Anemones (de Caen) single mixed, Paper white Narcissus, Acacia, carmine Ranunculus, white and pink Stocks, French Roman Hyacinths, and Parma Violets.

There is very little business in potatos at present, the growers being unable to get their supplies forward.

REMARKS. Supplies of English Apples are now shortening, but fairly large supplies of French Russets are available. English Grapes are becoming scarcer, but there are fairly large stocks on hand of Almeria (Spanish) Grapes. Oranges and Lemons remain a limited commodity. Forced vegetables on sale consist of the following: Seakale, Asparagus, Mushrooms, French Dwarf Beans, New Potatos, and Peas. Outdoor vegetables and fruits continue plentiful. *F. H. R., Covent Garden Market, February 27, 1918.*

DEBATING SOCIETIES.

BATH GARDENERS'. A lecture on "How to Grow Onions" was given on February 18 at the Oddfellows' Hall by Mr. W. Taylor, Mr. C. F. Langdon (vice-chairman) presided over a good attendance. Mr. Taylor said although the Onion grown in the ordinary way appeared to be nearly on the surface it was of deep-rooting and gross-feeding vegetable and paid for good tillage. Dealing with the early sowing of seed in boxes, Mr. Taylor said transplanted Onions had the advantage over those left where they were sown, in regard to the attacks of the Onion fly, as the bulb was placed below the surface, and it was very seldom the fly found it.

GARDENING APPOINTMENTS.

MR. FEAKS, Forester to LOCHIEL (Cameron of Lochiel), at Achnacarry, Fort William, in succession to the late Mr. SCOTT, on the Earl of MORAY'S Estates at Darnaway and Castle Stuart.

MR. ROBERT SCOTT the eldest son of Mr. WILLIAM SCOTT, who recently retired, after over 30 years' service, from his post as Head Gardener at Drumpark, Dunragit, Kirkcudbrightshire, who has been for 24 years Superintendent on the Estate of Holmesdale, Pittsfield, Massachusetts, U.S.A., as Superintendent Gardener to Mr. ANDREW CARNEGIE, Shadowbrook, Lenox.

SCHEDULE RECEIVED.

National Carnation and Picotee Society's (Southern Section) Exhibition, to be held in the Drill Hall, Buckingham Gate, Westminster, on Tuesday, July 16, 1918. Hon. secretary, Mr. J. J. Keen, 61, The Avenue, Southampton.

CATALOGUE RECEIVED.

SUTTON & SONS, Reading.—Farm seeds.

"There are few gardeners, and still fewer amateurs, who do not on occasion require immediate information upon various points of practice. But either from an unwillingness to inquire or from not knowing of whom to make the enquiry, they too often fail to obtain the information they are in want of. And let no one be alarmed lest his questions should appear trifling, or those of a person ignorant of that which he ought to know. He is the wisest man who is conscious of his ignorance; for how little do the wisest really know!—except that they know little. If one man is unacquainted with a fact, however common, it is probable that hundreds of others in the same position as himself are equally in want of similar information. To ask a question, then, is to consult the good of others as well as of one's self."—*Gardeners' Chronicle, No. 1, Vol. I., January 7, 1871.*

ACORNS *A. T. H.* The easiest method of treating Acorns is to sow them thinly broadcast in beds about 3 feet wide. The Acorns should be 1 inch or so apart, and be covered with about 2 inches of fine soil trodden firmly after sowing. They should be sown in March as soon as the ground is in suitable condition. Acorns germinate in the first year, and should remain in the seed bed until the end of the second year, when the seedlings should be taken up, the roots trimmed and shortened, and laid in the soil until the following spring, when they can be planted out in nursery rows 6 inches apart and 1 foot from row to row. Mice, rooks, and pigeons will search for and destroy Acorns after they are planted, and this must be guarded against.

ASPARAGUS *B. L. O. B.* Asparagus beds should be well drained. If the soil is wet and of a heavy texture raise the bed about 1 foot above the ground level; in light soils Asparagus beds may be made on the flat. Trench the ground 2½ feet deep and give it a heavy dressing of manure. In the case of heavy land use plenty of light soil, road-scrapings, and other materials that would lighten it. Make the beds 4 feet in width, allowing for three rows of plants to each bed, one in the centre, and those at the sides 10 inches from the edge, placing the plants alternately with one another. Expose the roots as little as possible, spread them out carefully, and set the plants 15 inches apart, covering them with about 3 inches of fine soil. Connover's Colossal and Reading Giant are suitable varieties.

BEDDING PELARGONIUMS. *B.* The blooms should be picked off the Pelargonium plants until the latter are placed in the beds.

BUTTERCUPS ON A LAWN. *C. H.* Ploughing would not kill the weeds, whilst the application of weed killer would render the soil sterile to growth for a long time. Goats would not exterminate the weeds; indeed, the manure from the animals would probably cause the weeds to grow faster. Trenching the ground 16 inches deep and burying the weeds at the bottom spit would get rid of them, and the land would grow a full crop of green food the first year, and afterwards any other crop under good management. The sowing of seeds the first year in such land without adding fine soil in the rows would be a difficult matter.

JERUSALEM ARTICHOKES. *J. H. L.* The Jerusalem Artichoke cannot be depended upon to flower in this country, consequently it is useless to grow for producing seeds as food for poultry. It would be far better to grow the giant Russian Sunflower for poultry food. The tubers of the Jerusalem Artichoke could be used as food for pigs, but certain other crops would be more profitable in this respect. To obtain a heavy crop of the tubers the ground should be well trenched and deeply dug, and heavy manuring, as recommended on p. 90.

MANURE FOR FRUIT TREES. *Young.* Potash, in the form of kainit or chlorides is beneficial to all kinds of fruit when the soil does not contain enough in an available form, and withholding it from a nutritive point of view. Woburn experiments had more effect than the absence of any other manure, but it is improbable that you can obtain potash at the present time. Moreover, dung in nearly all experiments has had a greater effect than potash alone or any mixture of artificial manures. Potash and any stimulating manures containing nitrogen have more immediate effect upon the growth of fruit trees than upon fruiting, but growth is essential to obtain length of branches which will be capable of furnishing sooner or later the greatest quantity of fruit that a tree can bear. Similarly with Strawberries, such manures affect the size of the plants more than the number of fruits, though vigour in plants is essential to size of fruit. A dressing of dung at the present time would be the best application for Strawberries. Potash manures have proved particularly valuable for bush fruits, but there is enough potash in dung. A moderate dressing of dung, say, 15 tons per acre, is quite sufficient for Strawberries, and an extra quantity did no good at Woburn. As dung and potash alone are slow-acting manures, the present is a good time for their application. When kainit can be obtained, 4 cwt. per acre would be a fair dressing. Where dung is not obtainable, a complete dressing of artificials, such as 4 cwt. of superphosphate, 2 cwt of nitrate of soda, and 4 cwt of kainit or 2 cwt of sulphate of potash per acre might prove valuable for all kinds of fruit, applied in April or May. The present times is too early for the application of nitrogenous manures, as they are liable to be washed away before they can be utilised, if applied too early in the season. Such a mixture proved highly beneficial to bush fruits, and particularly to Gooseberries, at Woburn, but a liberal dressing of dung was better still, and at present a complete dressing of artificials is not obtainable, owing to lack of potash. Most soils contain enough iron for fruit, and there is not sufficient evidence of applications of sulphate of iron having had any regularly beneficial effect. Very few experiments have been tried with it. Three pounds per tree of fair size, as far as the spread of the branches, would be a good dressing. Basic slag or other phosphatic manure by itself has failed to show any obvious effect upon fruit trees, and at Woburn its withholding from a complete mixture of artificials seemed to be beneficial, though this may have been accidental.

NAMES OF PLANTS: *J. N. B.* 1, Cupressus pisifera var. squarrosa; 2, Cryptomeria japonica var. elegans; 3, Thuya dolabrata.—*J. O.* 1 and 5, Picea excelsa; 2, Picea Omorika; 3, Pseudotsuga Douglasii; 4, Thuya dolabrata. *W. M. M.* Cypripedium gigas (Harrisianum × Lawrenceanum). This plant has never been recorded under the name you give.—*Dublin.* Daphne Laureola (Spurge Laurel).—*L. S.* Apparently a form of Berberis aristata. It might possibly be B. umbellata, though your description of the colour of the fruits does not agree with that species, as B. umbellata has oblong red fruit, whilst B. aristata and its varieties have long red fruits covered with bluish-white bloom, which would give them a purplish appearance.

SALT. *J. W.* Common salt is sodium chloride, and is often used as a weed-killer, or as a preventive of wire-worms in soil. It is occasionally employed as a top dressing for Asparagus, as it helps to retain moisture in the soil, but it is in no sense a plant food.

SCABBY POTATOS: *Constant Reader.* The grey, silvery patches on some of the tubers are the "silver scurf," caused by the fungus Spondylocladium atrovirens. This is not a serious disease. The rusty-brown markings under the skin of the other diseased tubers are characteristic of the common "blight" of the Potato. Obtain the free illustrated leaflet on Potato spraying from the Food Production Department, 72, Victoria Street, London, S.W. 1.

SEAKALE AND GLOBE ARTICHOKES. *B.* Seakale should be planted in March, and Globe Artichokes in April, in deeply dug and well-prepared ground.

SUGAR BEET. *R. M. P.* See p. 6 in the issue for January 5, 1918.

THE CULTIVATION OF CANTELOUP MELONS: *S. B.* For general purposes the variety should be sown in three batches, from March 15 to April 15. Insert the seeds in shallow pans filled with soil consisting of one half good loam and one-half well-decayed manure and germinate them in a temperature from 65° to 70° F. As soon as the cotyledons are well developed, place the plants in 3-inch pots filled with the same kind of compost, and grow them at the same temperature as advised for the seeds. The provision of light shading, occasional sprayings, and a little ventilation during the sunny hours will be all the attention needed by the young plants. Eight or ten days after the plants are potted a hot bed, 10 to 12 inches thick, should be made out of doors in a well sheltered and sunny situation to accommodate a frame filled with sufficient soil for plunging the pots. Set the plants in the frame as soon as the bed is sufficiently warmed, allowing the necessary space for future growth. From this stage the plants should be kept moist at the roots, shaded during the brightest parts of the day, and allowed a little ventilation daily. Cover the lights at night to maintain an even temperature. When the fourth leaf develops stop the plants at the second leaf and remove the cotyledons close to the stem with a sharp knife. At that stage prepare the final quarters for the plants. The most suitable place is a situation facing south, and sheltered from cold winds. Make a trench 8 to 10 inches deep and 2 feet 6 inches wide, and fill it with horse-straw manure, which should be firmly trodden down and watered if necessary. Place the frames over the manure in the trench and fill them with rich garden soil, mounding it 3 or 4 inches higher in the centre. When brick pits or very deep frames are used the manure bed is made inside the pits or frames, instead of in a trench. When the compost is warm to the hand set the Melon plants in the centre; two are generally sufficient to each light, though some growers set three in a triangle. Keep the lights closed and shaded from 9 a.m. to 3 p.m. till the plants are well established. Afford only a little ventilation at first, increasing the amount gradually; discontinue the shading altogether as growth proceeds and the weather gets warmer. Close the lights late in the afternoon and cover them at night. The plants will require watering on a bright morning within 12 to 15 days after they have been set; they should be kept rather dry within reason till the fruits are the size of a Walnut, but from that time the ground should be kept in a moist condition, consistent both with the growth and the weather. Early in July the frame should be ventilated at night and the protective material dispensed with altogether. During hot weather the lights may be removed, but should be placed in position again when the atmospheric conditions are not so favourable. When the Melons have been 15 to 20 days in their final quarter the two shoots growing from the base of the leaves will have developed into two stems, bearing five to seven leaves each. Direct one of them towards the front and the other towards the back of the frame, and stop them at the fourth or fifth leaf. This operation will cause side shoots to develop, and these will eventually bear the best fruits. Stop the side growths at their second leaf, or the leaf immediately over the fruit. The fruits set freely without artificial pollination provided the details in regard to ventilation have been well attended to. Leave two fruits of even size to each plant; this number may be exceeded when the growth is very luxuriant, and when only medium-sized fruits are required. The fruits should be turned occasionally to ripen them evenly. The removal of crowded shoots or decayed leaves is all the pruning necessary.

VINES: *E. B.* Prune the vines at once. If the pruning is deferred until April the cut surfaces will "bleed," and the flow of sap be difficult to stop. Dressing the wounds with Thompson's Styptic is the best means of preventing "bleeding."

NOTES FROM KEW.—III.*

ALL things considered, Kew continues to attract and interest the public as much as ever it did. Given a fine Sunday afternoon in February, four or five thousand visitors pay their pennies to enjoy themselves in the grounds and houses (only one museum has been open since the common enemy of the wall). There is not much in February for seekers after floral delights, but Kew is Kew, and as a large proportion of the visitors now-a-days are soldiers, either Colonial or from a distance, they find plenty to interest them. On week days comparatively few people come: three or four hundred the average—and they are mostly men in khaki. Most folk are busy with other matters in the week. Those who knew Kew twenty-five years ago, a quiet village famous for its great national garden, would find it much changed now. It is no longer a village, but an important part of the borough of Richmond, and the present Mayor is a Kew man, as his predecessor was. The market gardens have been displaced by a network of streets and roads, lined with villas. Fleets of motor 'buses and Army lorries roar through the main road from early morning till midnight and after, carrying workers of both sexes. One wonders if the gardens are to be stifled out of Kew by smoke and other poisons which fill the atmosphere and make the healthy cultivation of plants far more difficult than it was when Kew was a little village in the country.

The mild weather during the first half of February brought many plants into active growth. Fortunately, a change set in on the 17th, and we had about ten degrees of frost on four successive nights. Harm is well as prospective good were done, for whilst growth was arrested some plants paid the penalty of coming out too soon. Rhododendron Nobleanum, R. barbatum, R. dahuricum, R. Fargesii, and R. sutchuenense, which were nicely in flower, were spoilt, though some of the less forward buds escaped and developed later. Early flowering Rhododendrons are not an unmixed blessing, except in those parts of the country where frost is less destructive.

Whilst on the subject of Rhododendrons, I may mention R. praecox, a good, showy plant outside in early spring, but of far greater value for forcing. The bushes may be lifted from the open ground in January and placed in a little warmth, where in about six weeks they will be in full bloom. R. strigillosum is flowering outside, and notwithstanding a difference in the leaves, I believe this is merely a Chinese form of R. barbatum. Other Chinese species too

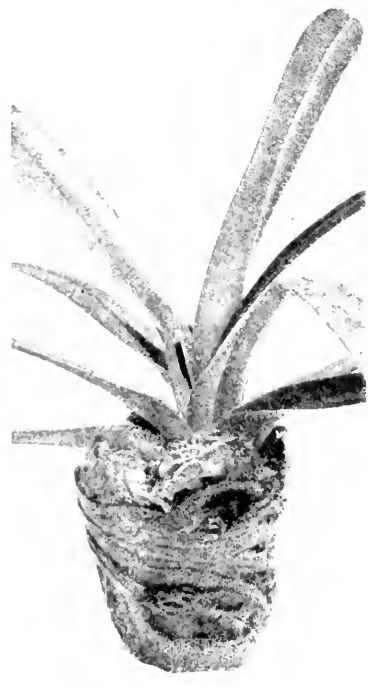

FIG. 21.—PLANT OF CYPRIPEDIUM MOUNTED IN SPONGE WASTE.

called now in flower are R. concinnum, R. Davidsonianum and R. Fargesii, and it is not easy to find a justification for their separate name. They seem slight variants of one species, and may well be called R. Fargesii, which, I suppose, the oldest name. But life is too short to worry over names and the vagaries of the taxonomist too confusing. Over many names are less troublesome than wrong ones. Besides, "Let them name it who can, its beauty remains the same."

Forsythias are in full blow and the Lilac buds have burst. The early Magnolias, stellata and Yulan, are rapidly approaching perfection, and will, if they escape frost, make a brave show at Kew before March is out. What a noble evergreen M. grandiflora is. There are good examples of the plant in the Azalea garden, and the rich red-brown colour of many of the upturned leaves is as effective as flowers. It is singular how many of the leaves have lost, or perhaps never had, any felt covering on their undersides. Its absence does not appear to be due to exposure to wind or to any of many condition. One is reminded of Gregor Sutherlandii, which has some shoots with glabrous leaves, others with decidedly hairy ones. Magnolias and Azaleas will be a great open-air floral feast at Kew in a few weeks.

The only bulbs in the gardens out of doors are Crocuses on the grass mounds, and Daffodils, Snowdrops and Bluebells in the wild gardens and woods. The great displays of Tulips, Hyacinths, etc., in beds have ceased, and the beds are being got ready for the growing of vegetables. The Crocuses make some show, and the Daffodils have begun with pallidus praecox in the enclosure near Cumberland Gate. Here and there patches of the pink Heath Erica carnea are cheering. Gardeners should make more use of this plant for early spring effect. Another good but neglected shrub of the same order is Pieris japonica; the tassels of white bells are like bunches of Lily-of-the-Valley.

Several of the Prunes are in flower notwithstanding the frost, but the great army of spring flowering trees and shrubs will not be at their best until after this notice has appeared. Roses are in danger, for many of them have new shoots 3 inches long, the Ramblers generally being most forward. The Rose Garden near the Pagoda is in fine order. It has been considerably enlarged, and the plants having rooted well. They promise to make a gorgeous display this year. I would like to see a garden of Roses of the tea and hybrid tea varieties in which the plants were allowed to grow *au naturel*, no pruning whatever; also as far as possible, on their own roots. One of the parks might very properly start such a garden. The orthodox treatment for these Roses is severe.

It is a thousand pities that the Almond has not been made more of at Kew. What pictures would have grown up by this time if twenty years or so ago there had been planted as many Almond trees about the gardens as there are, say, Limes and Chestnuts. Another pitiable happening is the "tidying" of the fine collection of Ivies, formerly one of the prides of the arboretum. Ivies are named by and cultivated for their juvenile habit and foliage, and, as with "broken" Tulips, their characters depart when they change. However, there is interest in the variety of these forms that may now be seen at Kew. Possibly I am in error, though I think I have read it in an authoritative work, in saying that when once an Ivy has changed to the adult or true form, it cannot be induced to develop shoots of the juvenile or creeping form. Also that the change is not controllable.

Thanks to the generosity of the late Mr. O. Wrigley, Bury, Kew possesses a good collection of varieties of Clivia miniata. Many of the plants are in flower in the warmer end of the Temperate House. It is

* Previous articles appeared in the issues of January 19 and February 9.

remarkable, seeing how many seedlings of this Clivia have been raised in gardens, that so little variation in colour has been obtained. The flowers are all orange-red with a yellow throat; some are a darker shade than others, but nothing very pronounced. Variety in size and form of petal, and in the number of flowers in the umbel, has been got by breeding. So far as I know, only one hybrid Clivia has been raised, namely, C. cyrtanthiflorum, its parents being C. miniata and C. nobilis, and is it had little to recommend it probably it no longer exists. The genus is related to Cyrtanthus, also to Vallota, and it is not far removed from Nerine, a fact which may interest Mr. Elwes and the Rev. J. Jacob. Clivias are good-natured plants, and are suitable for standing in windows and halls, as they are able to withstand much rough treatment—as much perhaps as Aspidistra. They do well as door plants in the Palm House at Kew, which is about as severe a test as any of a plant's endurance. Other plants that can stand the same treatment are Aspidistra, Curculigo, some of the Crinums, the largest of the Hymenocallis, Pancratium and Eucharis. There are a few other monocotyledonous plants that can tough it, the following list of which may be useful to gardeners who have to furnish large tropical houses. Anthurium, Alpinia, Beschorneria, Bromeliads (any large species that are not too spiny), Caladium, Canna, Curculigo, Curculigo, Cyrtanthus, Dieffenbachia, Dracæna, Hedychium, Heliconia, Maranta, Musa, Pandanus, Spathiphyllum, Sparganium, Strelitzia, and Zingiber. Palms and Cycads are, of course, taken for granted in this category.

Streptocarpus, a hybrid between the tree-like S. Saxorum and the common dwarf, decidedly acaulescent S. Reginæ, is a remarkable plant with flowers of any size and is in flower in the Alpine and succulent Houses now. The species first flowered in 1917—here a photograph of it was reproduced in *Gard. Chron.*, April 2, 1910, p. 217. The cross was made in 1906, so that the hybrid was then eleven years old. In habit and leaf characters it takes after S. Saxorum, the male parent, the leaf-blade being ovate and about 18 inches wide, and the leaves distichous on a decided stem. But the flowers are like those of S. Reginæ except that the colour of the sepals is not rich orange, but a washed or pallid yellow; the petal-sheath is blue. A hybrid of this character may be taken as an indication of what might be done in tropical gardens in the way of crossing big, striking species. Musas offer splendid material. A hybrid Cycad has been raised in Europe, and the glorious Brownea Crawfurdii was raised in a garden in Cork. But no giant hybrid of artificial origin has come from a tropical garden. Calcutta, Ceylon, Singapore, Jamaica, Trinidad and Demerara ought to do work of this kind, not merely for scientific amusement, but with a view to improved races of food fruits and other economic values.

A Temperate House veteran was in all its winter glory in February, namely, the big specimen of Camellia reticulata; the bountiful display of bright crimson Paeony-like flowers are every year a source of wonder and delight to visitors. Mr. Wilson once told me that the common form of this Camellia in China was white-flowered, and that he had sent seeds of it to Messrs. James Veitch and Sons. I suppose they failed to grow, but another attempt might be made to introduce the plant.

There is a good display of flowers in No. 4 Greenhouse—fewer bulbous plants than in former years, but a good-sized group of Hippeastrums and a variety of hard-wooded plants, chief among the latter being a number of bushes of Rhododendron (Azalea) Kaempferi, with salmon-pink flowers. Kew is indebted to Professor Sargent for this most serviceable shrub. He sent seeds of it from the mountains of Japan about 30 years ago. Many plants were raised, and for years they have occupied a large bed in the formal garden behind the Palm House. They are quite hardy, but the flowers expanding early, they are liable to be spoilt by frost. Some of the most showy bushes were marked for special cultivation, and several were forced for the conservatory, where, last February and this, they were very attractive. The plants known as roseiflora, Hexe, Hinodegiri and amœna are, I believe, varieties of this very variable species, and not of R. indicum, as is generally supposed. Certainly R. Kaempferi deserves attention as a first-rate forcing shrub. The purple-leaved Begonia Mrs. Peterson, a variety of Gloire de Lorraine, is another effective plant in No. 4. The Waratah, Telopea speciosissima, is in flower in the Succulent House. The illustration in fig. 47 shows the inflorescence in the early stage before the cluster of flowers in the centre had expanded.

In the rock garden Squills and Chionodoxas blue the ground in places. Primula Winteri is also nicely in flower behind a rock and under the shelter of a pane of glass. The pick of the Saxifragas are the three hybrids Petraschii, Paulinae and Faldonside, and the bright-coloured form of S. oppositifolia known as Wetterhorn.

The photograph (fig. 44) shows a plant of Cypripedium growing in sponge waste, to which I referred in my last notes. *W. Watson.*

FIG. 45. SAXIFRAGA BURSERIANA SULPHUREA.
(R.H.S. Award of Merit, February 26, 1918.)

THE ALPINE GARDEN.

SAXIFRAGA BURSERIANA SULPHUREA.

THE full-sized illustration, fig. 45, depicts the new Saxifraga Burseriana sulphurea raised from Faldonside × S. Burseriana by Mr. G. H. Simpson Hayward, and exhibited by Messrs. R. Tucker and Sons at the meeting of the Royal Horticultural Society on the 26th ult., when the plant received an Award of Merit. As will be seen on reference to the figure, the flowers are large and regular in outline; the colour is pale sulphur-yellow. Judging by the fine specimen exhibited, the new variety grows vigorously and flowers with freedom. It makes a good companion to Faldonside, the delicate colour of the petals contrasting pleasingly with the intense yellow of the older variety.

PRIMULA MARVEN.

PRIMULA MARVEN, the result of a cross between P. marginata and P. venusta, is one of the most delightful of Primulas, though at present a rare one. I last saw the plant in bloom in the gardens of Dr. John MacWatt, at Morelands, Duns. Dr. MacWatt, as is well known, is a special authority on the European and other Primulas, and his collection of these flowers a very extensive one. There it was a pleasure to see Primula Marven, just as I saw it in the raiser's garden at Kaimes Lodge, Edinburgh, some years before. This beautiful Primula is like an Auricula in general appearance, but the flowers are blue-violet. The flower-stems are sturdy, and the leaves possess an elegant golden margin, derived from P. marginata.

RANUNCULUS ALPESTRIS.

ALTHOUGH Ranunculus alpestris is not a difficult plant to cultivate when its wants are supplied, there have been many failures to cultivate it satisfactorily. Where it thrives the snowy flowers, brightened by a yellow eye, are charming, and the spikes are raised above the dainty trilobate, glossy leaves. The roots need plenty of moisture; in a dry, parched soil the plant will look unhealthy. It needs to be planted in a wet soil or in moist shingle or stones, such as a wet moraine, and there it will be compellingly attractive, growing sturdily and healthily. In a soil of medium moisture the plant is fairly satisfactory. *S. Arnott.*

FRUIT REGISTER.

PLUM SUPREME.

PLUM SUPREME, sent out by Messrs. Laxton Bros., is a cross between Denniston's Superb and Victoria, and is a splendid variety in every respect. The tree crops heavily the second year after planting. I know of no Plum superior to this variety for making jam or bottling. As a second early dessert sort it comes in at a most useful time. The colour is similar to Denniston's Superb, and the flavour is good. The fruit does not crack during wet weather, which is a valuable asset. *E. Molyneux.*

ORCHID NOTES AND CLEANINGS.

CYMBIDIUM LYRA.

MR. W. WALKER, Orchid grower to G. Hamilton Smith, Esq., Northside, Leigh Woods, Bristol, sends flowers of a hybrid Cymbidium named Lyra, raised from C. eburneum and C. Gottianum (eburneum × insigne). The second introduction of C. eburneum has resulted in a change of form towards that species, the sepals being broader than in most hybrids of the section and the lip more openly displayed. The sepals and petals are white faintly tinged with rose; the lip is white striped and spotted over its entire surface with dark purple.

CYMBIDIUM SYBIL.

MR. WALKER also sends three flowers of Cymbidium Sybil, a cross between C. eburneum and C. Pauwelsii. The flowers show the great variation obtained from plants raised from seed of the same capsule. One flower is entirely white with a yellow callus on the lip; another blush-white with a band of rose on the front of the lip and small spots on the side lobes; and the third is pale buff colour with faint rose markings on the lip and a green line on the outside of the sepals.

PTEROSTYLIS CURTA.

IT is not often that a report is obtained of successful culture of many of the pretty Australian terrestrial Orchids, but specimens of Pterostylis curta have grown and flowered very freely in the Warren House Gardens, Stanmore, and are now in bloom in the cool Odontoglossum house, one plant bearing over fifty flowers. The bright green leaves are closely arranged near the base of the plant, the roots descending and bearing on each one or two small tubers. The inflorescence is about 6 inches in height, each stem bearing a single erect flower. The three upper segments are closely approached and arched over the column, which is whitish tinged with green. The bottom greenish sepals are connate in the lower half, whilst the free halves are erect and acuminate. The lip is lanceolate, erect and attached to the column at the base by a short strap; it is highly sensitive, and like other members of the same genus, gives ready facilities for fertilisation by insect aid. When the flower expands fully the lip reflexes over the lateral sepals, and quickly springs back when an insect alights on it or if it is artificially irritated. The lip remains closed for some time, but again returns to its position in front. The species is figured in the *Botanical Magazine*, t. 3,086.

MORE SPRING FLOWERS.

AT the risk of repeating myself, I cannot help recommending every gardener to endeavour by hook or crook to get seeds of Iris Rosenbachiana, and not rest content until he has a whole frame full of seedlings. Just at present I have some 40 or 50 plants in bloom, and each one is a little different to its neighbours. The astonishing thing is the ease with which they are grown. It is only necessary to top-dress the soil with old manure and well decayed leaf mould in autumn, to put a light on to the frame to protect the flowers when the broad shoots come through the soil, and to leave it on all through the summer so that the soil may become as hot and dry as possible. Then for six weeks early in the year that frame will always be the chief attraction of the garden.

After trying for years to raise Iris reticulata from seed without success, I have this year had a number in flower. When I say without success, I mean that seedlings of the blue purple type have always given me red purple Kraelages. Now, however, seedlings of these red forms have flowered and given me reds and blues in approximately equal numbers, though the reds slightly predominate. Some of these seedlings seem to my possibly prejudiced eye superior to the well-known type. It remains to be seen which of them, if any, will prove to have a good constitution.

Does any reader know a dwarf white flowered Colchicum from Croatia, which flowers in mid winter or very early in the year? It has two or three leaves of a very dark grey green, lying nearly flat on the ground, and sends up 4 or 5 sturdy little flowers, with an occasional variation bordering on pink. The plant is quite hardy here, though last winter was sufficiently trying, and I was actually able to save a number of seeds of it last summer.

Most of my latest Crocus species are now passing over. The most richly coloured is the Corsican *C. minimus*, of a deep lilac colour, with strongly marked darker feathering on the outer segments. *C. laevis* deserves to be better known, for some of its forms are very beautiful, particularly a white form with blue featherings on the outer segments, and a dark purple base. The milk white form of *C. Imperati* goes on flowering for an astonishing length of time, and the recent frosts seem not to have harmed it. The foliage is characteristic, for it writhes about horizontally on the surface of the ground. The richly coloured *C. banaticus* is only just appearing through the surface.

Tulipa Kaufmanniana (see fig. 46) is very early this year, the first bud opening on February 23. It is not even then the first Tulip species to flower, for it is always beaten in the race by the little *T. biflora*. The latter seems to have numerous forms or closely allied local species. It is curious that a Tulip that comes into flower so early should yet be able to produce six or even eight flowers on its branching stem.

There has also been recently in flower a hybrid for which I am indebted to the kindness of Mr. J. G. Van Tubergen, of Haarlem. It results from a cross between the Mesopotamian Iris sindjarensis and the form of Iris persica known as Heldreichii or stenophylla. It has large flowers of a pale bluish lavender shade, rather paler than the lighter of the two shades of colour in the flowers of Heldreichii. It is a pleasing flower, but not so striking perhaps as the original cross with the typical *I. persica*. Alas, these round seeded Juno Irises are not for my light sand. They all dwindle more or less, and yet sindjarensis, persica, Willmottiana and Tubergeniana are among the best of the Juno Irises.

Why do small Tulip bulbs explore the neighbourhood by means of running stolons, while large bulbs of the same kind are content to flower where they are planted and not send out runners? Some year or two ago, Tulipa Orphanidea was planted in a pocket in my rockery, and when the bulbs were lifted one was overlooked. To-day I dug up four small descendants of that small bulb which had scattered themselves about so that the farthest were a foot apart, and each had sent out a stolon 2 or 3 inches in length, evidently with the intention of spreading yet further. I have watched them carefully. The first year there was one leaf, and therefore one bulb. The next year there was one bulb in the same place and another 2 or 3 inches away. By this year each of those two had given rise to two, for my experience is that a bulb usually forms in the position of the original bulb, as well as another at the end of the stolon. *H. R. Dykes, Charterhouse, Godalming.*

FIG. 46.—TULIPA KAUFMANNIANA: COLOUR OF FLOWERS WHITE WITH YELLOW CENTRE.

NEW OR NOTEWORTHY PLANTS.

RHODODENDRON RIRIEI, HEMS. AND WILS.

THIS Chinese species of Rhododendron was first described in the *Kew Bulletin* for 1910, p. 111, by Dr. Hemsley and Mr. E. H. Wilson. It was discovered in Szechuan and introduced by Wilson whilst collecting on behalf of Messrs. James Veitch and Sons about 1904. I have no knowledge that the plant flowered in this country before 1916, but it may have done so. This year it is blossoming in several places, and an opportunity is thereby afforded of adding to and amending the original description. The type specimen in the Kew Herbarium has only one damaged flower. In the first place the authors describe the flowers as white, a statement copied by Lieut.-Comm. J. G. Millais in his new book *Rhododendrons and the Various Hybrids*, and by myself in *Trees and Shrubs Hardy in the British Isles*. All the flowers I have seen or had accounts of are purple with a black patch at the base of the corolla. There may,

of course, be a white-flowered form in a wild state; if not, Mr. Wilson's memory as to colour must have been at fault. He describes R. Ririei as a bush up to 20 feet high. The leaves are narrowly oval or obovate, 4 to 6 inches long, 1½ to 2 inches wide, dull dark green above, and of a greyish-silvery or metallic hue beneath. I have seen trusses with six or seven flowers, but Wilson states that they carry as many as ten blooms. The corolla is 2½ inches wide, of an elongated bell-shape, five-lobed, purple (of a shade resembling R. campanulatum), with a black patch surrounding the ovary. The stamens are ten, quite smooth and scarcely as long as the corolla; the style is rather longer than the stamens, and free from down or scales; the ovary is covered with a minute felt; calyx with five unequal, subulate teeth 1-16 to 1-8 inch long. Opening at this early period of the year, the blossoms will be liable to damage by frost, and for that reason the species will probably be better suited for gardens in the S.W. counties than for places where the springs are colder. The plant itself appears to be quite hardy. *W. J. Bean.*

NOTICES OF BOOKS.

THE FLORA OF THE NORTHERN TERRITORY OF AUSTRALIA.*

THE record of what was known of the botany of North Australia existed only in a scattered condition in various publications; therefore the present consolidation will be welcome and useful, though wanting in uniformity of plan and composition. The book contains too much of matter that is out of place in a work of this kind, and too little information on some points of practical interest. For example, under each genus the various, often numerous, synonyms are cited, whereas specific synonyms are often omitted. Of course, many genera are unhampered by synonyms, whilst others have from half-a-dozen to five-and-twenty. But a short account of what the book contains will be of more service than a criticism of details. Taking the matter in sequence the map comes first. This is a route map of the "Barclay Expedition," from 12° to 20° S. lat., crossing 151° to 137° E. long., and filled up with the names of the characteristic plants. Among the commonest genera are Brachychiton, Capparis, Eremophila, Banksia, Grevillea, Hakea, and Persoonia, but only one species of Acacia is included, and not one species of Eucalyptus, though both these genera are represented by very numerous species in the territory. No member of Cycadeae, Coniferae, or Palmae appears in this record of characteristic plants. A short preface and introductory note are followed by a list of the new genera and species described in the volume. Spathia is a remarkable new genus of Gramineae. The systematic enumeration occupies nearly 300 pages, and the descriptive part is practically limited to keys to the genera and species. Mr. Maiden contributes separate synopses of the species of Acacia and Eucalyptus, and Mr. Cheel of the rest of the Myotaceae, including an elaborate review of the varieties of Melaleuca Leucadendron, while Mr. Hamilton is responsible for the Cyperaceae. There are also lists of fodder, poisonous and medicinal plants, and a list of popular names and of valuable woods. No analytical summary is given, and there is no sketch of the general vegetation of the country. *W. B. H.*

* *The Flora of the Northern Territory.* By Alfred J. Ewart, D.Sc., Professor of Botany in the University of Melbourne, and Olive B. Davis, M.Sc., with appendices by J. H. Maiden, F.R.S., Director of the Sydney Botanic Gardens, and by A. A. Hamilton and Edwin Cheel. Illustrations by Ethel McLennan, B.Sc., Isabel Cookson, B.Sc., Ellinor Archer, B.Sc., and Margaret Flockton. Sydney: pp. 632, with 27 plates and a map. Published by the authority of the Minister for Home and Territories (McCarron, Bird & Co., Melbourne.) 1917

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

TOMATOS.—Make a sowing of Tomato seed to obtain strong plants in readiness for planting out-of-doors in May. Grow the seedlings in a light position in a warm glasshouse after they have been potted, to keep them strong and sturdy. Pollinate the flowers as they open, and, as soon as the fruits begin to swell, top-dress the roots with rich loam. Water the plants with weak stimulants, and sprinkle a little concentrated fertiliser on the soil in the pots at short intervals. Remove all side growths as they appear. Continue to pot on young plants for successional fruiting, using a slightly richer compost for the final potting. Admit a little air on all favourable occasions, and let the temperature of the house range from 55° on cold nights to 65° by day.

CELERY.—Guard against crowding seedling Celery, which should be pricked off in boxes as soon as the plants are large enough to handle. Fill the boxes with rich, light soil, and grow the plants in a light position, free from draughts, in a house or frame of moderate warmth. The main sowing may be made at the end of the present month. Sow the seeds thinly, and keep the house close until the seeds have germinated. Afterwards admit air in gradually increasing quantities on all favourable occasions. Suitable varieties for the main sowing are Aldenham Prize Pink, Wright's Giant White, Standard Bearer, and Major Clarke.

FRENCH BEANS.—Frequent applications of liquid manure should be given to plants of French Beans from which pods are being gathered. Plenty of water and atmospheric moisture are necessary to keep the plants in a healthy condition. Top-dress later plants with rich loam mixed with manure from a spent Mushroom-bed. Grow the plants in a light position, and syringe them freely twice a day to prevent attacks of red spider. Continue to sow seeds at short intervals to ensure a constant supply of pods.

RADISHES. Where a constant supply of Radishes is required, seeds may be sown about every ten days. The plants may be raised in cold frames, or even in sheltered positions out-of-doors. Sowings may also be made on warm borders and the plants protected in very cold weather by untrimmed Pea sticks and strawy litter. Webb's Crimson Globe and Wood's Frame are two excellent varieties for early use. For later sowings use a mixed selection.

CARROTS IN FRAMES.—Thin seedling Carrots in frames to about 2 inches apart and water them afterwards to settle the soil about the roots. Increase the amount of ventilation during favourable weather; Carrots grown in an excessively close atmosphere make too much top growth. Make further small sowings, in frames for the present, on gentle hot-beds, to encourage quick growth, of the varieties mentioned in the Calendar of January 12.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

EPIDENDRUM.—Plants of E. vitellinum are developing fresh roots, and any that require repotting should receive attention. This Orchid resents root disturbance. Therefore any plants that are growing in pots sufficiently large to accommodate their new pseudo-bulbs may remain in the same receptacle for another season, provided the compost is not impoverished or sour. Newly potted plants should be watered sparingly until after the young growths are 2 or 3 inches long, when moisture should be applied liberally until the new pseudo-bulbs have completed their growth. This species grows well in a light position in a cool house. Epidendrums of the radicans section, such as E. Burtonii, E. O'Brienianum, and E. Boundii are rooting freely, and plants that have become unsightly and require repotting should be attended to at once. The long, straggling stems should be taken off just below where the new aerial roots are developing. The stems may be potted singly in small pots, or several may be placed together to form specimens. The plants require an intermediate temperature, and during their growing season a plentiful supply of water at the roots. Epiphronites Veitchii is a pretty bigeneric hybrid, raised from Sophronitis grandiflora and Epidendrum radicans. It is very similar in habit to the last-named parent, and continually develops roots from the stem. The treatment of the plant should be similar to that recommended for E. radicans. The plants grow and flower well in pans suspended from the roof-rafters of an intermediate house.

MANAGEMENT OF THE HOUSES.—March is a busy month for the Orchid grower, and, with increased light and sunshine, each division will require more attention in the matters of ventilating, shading, and atmospheric moisture. The temperatures may range a few degrees higher than hitherto, and the atmospheric moisture may be increased. For the present the temperatures should be as follows:—East Indian, or warm house: day, 70°, night 65°; Cattleya and intermediate house: day, 65°, night, 60°; Odontoglossum, or cool house: day, 55° to 60°, night, 55°. Each house will need damping two or three times daily. Every attention should be given the plants to enable them to make strong, healthy growths. The young shoots and leaves are very tender, and will soon be scorched and disfigured if exposed to direct sunlight. Discretion must be exercised in the use of the blinds. It is advisable to be on the safe side by not unduly exposing the plants to the sun's rays; at the same time the blinds should not be allowed to remain down longer than is absolutely necessary. Already the warmth from the sun has, on several occasions, had the effect of raising the temperatures of the houses higher than is necessary for many of the plants. Cold winds often alternate with bright bursts of sunshine, the external temperature being, perhaps, only 40° or even lower; in these conditions it is not advisable to admit fresh air in sufficient quantities to keep down the temperature, but to lower the blinds. When the outside temperature rises to 45° the amount of ventilation may be increased, and shade afforded with discretion. Open the ventilators under the stages, if possible, on the side of the house that is sheltered from the wind. These remarks apply more especially to many of the plants in the East Indian, or warm house, including Phalaenopsis, Angraecum, Bulbophyllum, and the warm-growing Cypripediums, also to the cooler houses containing Odontoglossums, Masdevallias, and cool-growing Cypripediums. For the present the Cattleya and intermediate houses will only require shading for an hour or so during the middle of the day. Plants in these last-named houses that require an extra amount of shade should be placed at one end, where they may be dealt with independently of the others.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

THE MULBERRY.—The Mulberry, Morus nigra, is principally regarded as a decorative tree rather than from the utilitarian standpoint for its fruits. It is a fruit, however, that amply repays for special attention in cultivation. The roots need plenty of moisture, and they should be mulched occasionally with animal manure. The trees are often growing in situations where it is difficult to give them this attention; for example, on lawns. It would, however, be worth while to lift the turf from around such trees, removing some of the exhausted soil, and replacing it with good turfy loam and well rotted farmyard manure broken down finely. If when doing this the soil is found to be dry, let it have a good soaking of water first. Make the surface dressing as firm as possible, and sow in April with grass seeds in preference to re-turfing, although it would be an advantage to

the tree to allow the soil to be clear of growth in a circle from 6 to 8 feet in diameter for a season. In addition to giving this attention to the roots, thin out all weakly shoots and remove the dead growth. In transplanting a Mulberry tree do not mound up the soil but plant it quite on the flat, or even a trifle below the level of the surrounding soil. The present month is the most suitable time to do this work. I have noted the Mulberry for some years past, and am of the opinion that there are different varieties, for the fruits of some trees are much superior to those of others. Colonel Durand, in his book, *The Making of a Frontier*, alludes to the fine varieties of the Mulberry that he met with in Northern India. A well known characteristic of the Mulberry is its prolific cropping, and at such times as the present the berries will be found most useful for preserving.

GRAFTING APPLES AND PEARS. The following remarks apply principally to what may be termed double grafting, or the grafting of established trees, rather than to grafting young stocks as carried out in fruit nurseries. Double grafting is performed by necessity in the case of certain varieties to improve both their fertility and the flavour of the fruits, but this has reference to Pears rather than to Apples, and does not call for remark here. Before re-grafting is decided upon in the case of established trees there should be some justifiable reason for its performance. It is an excellent means of obtaining a good sized fruiting tree of a new variety, or one that is not already in the collection. Never select an unhealthy tree for the purpose, but one that is in full vigour, and, for preference, one that has not been remarkable for its fertility in the past. Judgment is needed as to the amount of grafts that can be inserted on the stock to make it a shapely specimen. I have had experience with horizontally trained wall Pears that were re-grafted; re-grafting such trees offers one of the simplest and best means of adding a new or choice variety to the collection. The best systems of grafting are cleft grafting, rind or crown grafting, and notch grafting.

SUCKER GROWTHS. Take an early opportunity to remove suckers before the trees start into growth. Possibly Plums are the most troublesome trees in this respect. The suckers of Plum trees need to be looked at from wherever they arise, and this is sometimes a troublesome task; I have known suckers from Plums to appear on the opposite side of the path. Sever the suckers close to the roots and cut them clean away; do not casually sever them, for carelessness in this respect might mean a repetition of the evil.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

PELARGONIUM.—Pelargonium plants may be transferred from cutting boxes to pots at any convenient time, though there is no hurry. Strong plants should be placed in 4 or 5 inch pots, arranging some of the roughest of the compost, or coarse leaf mould, at the bottom of each pot for drainage. Much labour is involved in watering Pelargoniums, and many of our old plants which were kept over last autumn are being left in the cutting boxes in which they have been ever since, and they will have only a surfacing of new soil mixed with superphosphate to carry them on. Eight or ten days previous to placing the plants in the beds a sharp knife will be run lengthwise and crosswise between the plants, and to remove them from the boxes one side of each box will be removed and the plants carefully lifted out, planted without delay, and soaked with water. At one time not a few gardeners used to tie the roots of each plant in a handful of moss containing a little soil, and then place them close together in boxes, which also was a means of saving labour in applying water. Cuttings of these plants may be inserted now, but if the heat available be insufficient to favour quick rooting it is to be preferred to delay inserting them for a few weeks longer. When striking quantities of the cuttings we have found them do quite well in a bed of soil in one of the heated pits, and in cutting boxes. But no doubt 3 inch pots are better, water being more easy to give or withhold, and fewer losses resulting. They will succeed in a very high temperature and root all the sooner in considerable warmth, but not a moist heat, else there will be many losses.

MONTBRETIA.—If the soil is in good condition Montbretias may be planted forthwith, putting 2 or 3 of the corms in little clumps and the groups 6 to 9 inches apart, according to the variety. Let them be inserted at least 6 inches deep in soil that has been freely manured. Of the dark varieties Vulcan is the most telling in the mass, and perhaps the best of all for bedding purposes.

RANUNCULUS. The old-fashioned strains of Ranunculus are very quaint, but the most effective are of the section known as "French." The corms should be planted as soon as convenient 2 inches deep, claws downwards, and they need not be more than 2 inches apart, with just space between the rows to permit of hoeing.

HOLLYHOCK.—Nothing is gained by keeping strong seedling Hollyhocks longer out of the ground. The Hollyhock is fairly hardy, and the sooner the plants are established in the ground now the better they will thrive through the summer. Provide a deep rooting medium with a large proportion of rotted dung in it; rotted cow manure for preference.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs DEMPSTER, Keele Hall, Newcastle, Staffordshire.

PREPARING NEW VINE BORDERS.—Where a commencement is to be made in planting young vines during the month of March, the borders should be made in advance of the time proposed for planting, as essential that the degree of fermentation should be subsided before the roots are allowed to extend to them. For an inside border 12 feet wide, with a lean-to of 3 feet wide, it will require 1.2 feet more than is needed for the inside border alone to obtain a depth of 3 feet wide. A width of 4 feet will be ample for the first year, or probably two. Efficient drainage is a very important detail, especially if the ground is in a low situation and naturally damp. On some soils it is not necessary to provide much drainage material, but in other situations in this respect must be needed, and the grower must use his discretion. The bulk of the compost should consist of fibrous loam, chopped roughly into moderate-sized pieces. To the loam add a limited quantity of half-inch bones, charcoal and some manure. Lime in some form, for preference mortar rubble or broken bricks, with the mortar still adhering, is necessary to keep the soil sweet. The proportion of lime used should depend on the nature and texture of the loam. Some growers, when making new vine borders, place the materials in layers probably with good results, but it is better to mix the compost under an open shed where it can be turned several times before it is placed in the vinery. Make the soil firm by treading for in a loose soil vines are apt to make a few long, thong-like roots, instead of short fibrous roots that would permeate the whole border. The turf retaining wall in one year, or at the most two years, should be a mass of fibrous roots then the border may be extended.

APRICOTS. Established Apricot trees are looking remarkably healthy this season, and are a mass of blossom. A cold, damp atmosphere is detrimental to the trees when in flower, therefore the hot water valves should be opened a little at night to dry the air. Close the valves again in the morning at 9 a.m. unless the weather is cold and wet. Drought at the roots will seriously check the growth of the trees, and although it is not good practice to water trees in flower, I would not hesitate to give sufficient tepid water to carry them through the flowering stage and thus prevent a check to root action.

STRAWBERRIES IN PITS. Strawberry plants plunged in a bed of leaves with the crowns near the roof glass should do exceptionally well now, as the days are lengthening and the sun gaining in power. Plenty of air should be given during the day when the sun and air are warm. The heat should only be gentle, for the plants will not bear much without having the effect of unduly drawing the foliage and flower-spikes. When growth has advanced sufficiently the plants should be removed to shelves near the roof-glass in a vinery or Peach house. In these houses, with a maximum amount of sunlight and air, the fruits will set readily. Vacant places in the pots may be replaced by other plants, and thus maintain a succession for forcing.

CORDON PLUMS.—Cordon Plum trees do remarkably well when grown in borders of suitable soil in Peach houses. The earliest possible date to start in flower in these gardens, and, together with the Peach and Nectarine trees, is a beautiful sight. The Plum trees invariably bear an excellent crop, and the fruits finish well. The ventilators are left open a little at night to clear the air to their fullest extent during warm, sunny weather. It is useless to attempt to hurry the growth of Plums; they must develop slowly if the fruit is to be well finished, moreover, the fruit never ripens properly in a close atmosphere, being without flavour or colour.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CYCLAMEN.—Old Cyclamen plants will continue to flower for some time to come if careful attention is given to watering. Draw down the blinds in bright weather or the flowers will lose their bright colours. This remark applies to all plants in flower. Cyclamen plants which have been selected for producing seed should be stood on a shelf in a cool house in full exposure to the sun. Give the roots plenty of stimulants till the seed is ripe. Young plants that were transferred to the seed pan into boxes in January are ready for placing in 5 inch pots. A compost consisting of fibrous loam, leaf mould, finely crushed brick rubble, and coarse sand is suitable. Grow the plants near the roof-glass in a warm, moist house, and spray them twice daily with lukewarm rain water.

PRIMULA ORCONICA. To obtain plants of this useful Primula for flowering in late autumn and winter sow the seeds now in shallow pans filled with a compost consisting of loam, leaf mould and sand. Thoroughly soak the soil with lukewarm water before sowing the seed. Cover the seed lightly with very fine soil, place a sheet of glass on the seed pan, and place them in a moderately warm house. Cover the glass with brown paper until the seedlings appear.

PRIMULA MALACOIDES. Make a sowing of Primula malacoides to obtain plants for autumn flowering; if necessary another sowing may be made later to raise plants for winter flowering. The seeds may be treated as advised for Primula obconica. Grow the plants in cool conditions all through the summer. When the flowers are developing, water the roots with extra care, or many of the flower spikes will damp off.

CINERARIA. The latest batch of Cinerarias should be grown in very cool conditions in order to extend their flowering season as long as possible. The house may be thrown wide open during fine, congenial weather, and the blinds lowered during the hottest part of the day. Fire-heat may be entirely dispensed with except when very severe frost threatens. Cinerarias need careful watering at all times, but a more liberal supply of moisture is necessary now that the pots are filled with roots and the days are longer. Stimulants may be given at every alternate watering. Watch for the leaf maggot, which is very destructive if allowed to spread. Lightly fumigate the house occasionally to destroy aphides.

CHRYSANTHEMUMS. Repot young Chrysanthemum plants as soon as they are sufficiently rooted, or they will receive a check to growth. Use a rich open compost, and pot firmly. Do not expose the plants to cold draughts, which are prevalent at this time of year. Recently potted plants should be kept in a close atmosphere for a few days, and afterwards grown slowly in cooler conditions. Another batch of cuttings may, if necessary, be inserted now. The shoots may be dibbled rather thickly into boxes containing sandy soil. Stand the boxes on a hot bed in a cold pit and keep them close and shaded until roots develop.

EDITORIAL NOTICE.

Editors and Publisher. – *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents. – *The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News. – *Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENTS FOR MARCH.

TUESDAY, MARCH 12—
Roy. Hort. Soc.'s Comms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 41°5.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, March 7, 10 a.m.: Bar. 30.1; temp. 44.5°. Weather—Dull.

The Development of British Horticulture.

The suggestion made by the President of the Board of Agriculture at the Fruit Conference referred to in last week's issue on p. 90, that the Board would welcome the formation of an advisory committee of fruit growers, deserves both to be adopted and extended. We should like to see established, if possible at once, a Horticultural Advisory Committee, comprising representatives of all the sections of the industry and craft of horticulture. It is true that the interests of horticulture are diverse, but it is no less true that all the various sections have some common interests. For example, all are interested in securing a simplification of the regulations, schedules, and bye-laws which govern railway transport, and all are concerned in knowing what conditions will obtain with respect to imports in the critical transition period between the beginning of peace and the full ensurement thereof. As an illustration of this community of interests between different sections of the horticultural trade we may mention the subject of agricultural baskets. Hitherto—at all events in recent years—we have relied in large measure on imported baskets, with the result that there is now a serious shortage of certain kinds of basket. To remedy that shortage is by no means easy, for the makers of baskets are busy with what may be presumed to be more remunerative basket work; and inasmuch as they can have no assurance that their services will be wanted after the war, they could hardly be expected, except on patriotic grounds, to turn their energies in large measure to the making of agricultural baskets. Nor is this the only aspect of this important subject which requires attention. The variety of agricultural baskets is almost as great as the variety of weights and measures, and we feel sure that if an advisory horticultural committee were established, one of the subjects to which it would give attention would be that of the simplification, standardisation, and better utilisation of the indispensable packages and baskets used for the distribution of horticultural produce.

Then, again, there is the question of the better utilisation of early districts for the production of vegetable crops which before the war were imported in such vast quantities. To assume that "whatever is is right," may be well enough for poets, but it is not satisfactory to practical men. A return of imports would show, we think, that much of the produce hitherto brought to this country could be raised as well and, ultimately, as cheaply in this country as in Holland, France, Italy, and other countries.

Yet another subject which might well engage the attention of such a committee is that concerned with the popularisation of vegetables as food. It is truly deplorable that at the present time, when food generally is scarce, that the public is apparently unable to make use of the root and green vegetables, of which there are plenty in the country. The reasons for this inability are partly our insufficient marketing arrangements; but mainly the deplorable ignorance of cooking which characterises the British people.

How many households, for instance, know how to make and enjoy vegetable soups? How many systematically use cooked Leeks or Celery as articles of winter diet, and how many know how to cook a Cabbage or Savoy? It is no exaggeration to say that if the ignorance of cooking which characterises so many of us were removed the consumption of vegetables could be increased by 50 per cent., and altogether to the benefit, not only of the producer, but also of the people at large.

Needless to say, there are many other subjects, some of more pressing importance than those already mentioned, that are ripe for consideration by a horticultural advisory committee, and it is therefore to be hoped that as swiftly as may be in the present difficult circumstances such a committee—taking all horticulture for its province—may be set up, with the object of advising and assisting the Board of Agriculture in promoting the interests and providing for the extension of British horticulture.

THE 1918 ONION CROP.—In view of high freights and restrictions in shipping, it is urgently important that the home production of Onions should be increased very largely. For many years past the percentage of Onions grown in this country in relation to the quantity consumed has been small, and therefore no necessity exists to interfere with the ordinary trade channels in order to ensure the grower a market. In order that the grower may be ensured an adequate return for his crops, the Food Controller announces that in the event of its becoming necessary to fix any maximum grower's prices for the British Onion crop of 1918, the prices will not be less than those indicated in the following scale: For delivery on or before November 1, £15 per ton f.o.r. or f.o.b.; for delivery from November 1 to January 1, £16 10s. per ton f.o.r. or f.o.b.; for delivery after January 1, £18 per ton f.o.r. or f.o.b.

NEW ALLOTMENT HOLDERS' UNION.—A meeting of allotment holders was held on Monday, the 4th inst., representing federations from towns in the Rochdale district. An address was given by Mr. CYRIL HARDING (of the National Union Executive, and secretary of London and Southern Allotments Federation), and it was afterwards decided to form a North-Western Branch of the National Union. A provisional council, with Mr. E. NOBLE, 71, South Street, Rochdale, as secretary, was formed to make the necessary arrangements.

NEW ROSES AT BAGATELLE.—We have received from the curator of the Rose gardens at Bagatelle the following announcement: "A trial of new Roses will be conducted in the park of Bagatelle, near Paris, in 1918-1919, as in past years. The plants, as far as possible, should have been raised in pots, and several specimens—five at least—must be sent to the Rosary of Bagatelle before April 30. A notice must be attached as to their origin and parentage, stating, if necessary, any special treatment required for the plants. The varieties sent will be planted in the public Rosary as soon as they reach Bagatelle. They will remain there until the month of October of the second year, so that the jury may be able to study, during two seasons, the flowering and habit of growth. Parcels by rail should be addressed to Roseraie de Bagatelle au Bois de Boulogne, en gare de Neuilly-Porte-Maillot-Paris, and letters to Le Conservateur des Promenades de Paris, 4, Route du Champ d'Entrainement par Neuilly (Seine)."

POULTRY KEEPERS' CLUB.—It is proposed to form a new society, in the form of a federation of all the existing poultry societies and clubs, with the above title. Its object is to form a central organisation to deal with food-supply, freightage, and other questions of interest to all poultry-keepers. The inaugural meeting, which is open to all poultry-keepers, is to be held at the Holborn Restaurant on the 16th inst., at 2 p.m.

GOVERNMENT DISTRIBUTION OF SEED POTATOS.—About 20,000 tons of seed Potatos have been ordered this season through the Food Production Department of the Board of Agriculture.

SHAKESPEARE'S HEROINES AND AMERICAN ROSES.—Catalogues and advertisements of American Roses indicate a happy thought on the part of a Rose grower in the United States in naming his new Roses after Shakespeare's heroines. If the Roses have anything of the immortal beauty of the heroines European raisers will have to look to their laurels. Happy though the thought be, there is a certain incongruity in its practice. What lover of Shakespeare's ladies—and who is not?—would admit that "Rosalind," for example, is a "glorified Ophelia"? The latter Rose, if it is to be true to its namesake, should be fragile and delicate and of pale hue, the former robust and sturdy and of brilliant colour!

THE MARKETING OF SURPLUS PRODUCE FROM ALLOTMENTS.—Schemes for creating marketing organisations in each county have been prepared by the Food Production Department, and are already being put into operation in some counties. The essential part of every scheme is the establishment in each village of a collecting depôt, to which all surpluses, however small, may be brought for packing and despatching to market. The Ministry of Food is giving encouragement to such schemes by undertaking to treat the Potato crop raised by small cultivators in 1918 on an equal footing with the crops of Potatos grown on farms. Provided that the

cultivators in each district will combine so that their produce may be bulked and transport may be saved, the State will purchase all the surplus main crop Potatos grown on holdings, no matter how small. Each small grower will therefore be able, whilst retaining for his own use all he needs, to sell all he does not want. There is no question of commandeering the produce of small cultivators. The Food Controller is merely inviting recognised marketing organisations to sell their surplus produce to him if they wish to do so. The Ministry of Food is prepared in a similar way to purchase surplus fruit grown by small cultivators. To insure that the smallest surplus shall be used it will be necessary for the collecting depôts to be linked up with one another and all of them to be brought under a County Marketing Association.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—In accordance with the resolution adopted at the annual general meeting, the committee of the Gardeners' Royal Benevolent Institution have sent to each unsuccessful candidate at the election the sum of £2. This is in addition to the amount which will be granted in due course from the "Victorian Era Fund."

SUGAR FOR JAM.—The Food Controller, after consultation with the Royal Commission on the Sugar Supply, announces that, so far as can be foreseen, it will be possible to allocate approximately 10,000 tons of sugar during the coming fruit season to enable private fruit-growers to convert their own fruit into jam. The allocation will be made by the Food Control Committees, with the help of the War Agricultural Executive Committees. Each private fruit grower to whom sugar is issued will be required to give an undertaking that the sugar will not be used for any other purpose. Every applicant to whom sugar is allotted will be credited with having 1½ lb. of jam in his possession for every pound of sugar supplied to him, and will be expected to forego the purchase of jam for his household to this extent. No private fruit-grower will be allotted for this purpose more than 10 lb. of sugar in respect of each person who is receiving rations of other commodities as a member of his household, except on an express undertaking that he will, if required, place at the disposal of the local food committee the jam made with sugar allotted to him beyond that amount. The actual amount allotted to each applicant will depend, however, on the supplies available and the applications received. All jam taken over by the local food committees will be paid for according to quality, at prices not exceeding the controlled wholesale prices. In determining the quantity of sugar to be allotted, due regard will be had to the quantity of fruit likely to be available, the number of members of the household, the facilities for preserving possessed by the applicant, and the general circumstances of each case. The Ministry of Food is also taking steps to instal a number of pulping stations in the principal fruit-growing districts in addition to those established last season by the Food Production Department, which have now passed into the hands of the Food Controller. It is estimated that fruit pulped by the process adopted by the Department will keep for at least two years and can be made into jam at any time by the addition of sugar. When fuller details are settled they will be announced in the public press, and it is specially requested that no one will write at present to the Food Controller or any other Government Department asking for any further particulars, as the Controller is already overwhelmed with correspondence. It is expected that the distribution will take place at the beginning of June.

PUBLICATIONS RECEIVED.—***Superfluous Wood in Fruit and other Trees: The Remedy.*** By C. Martin, County Horticultural Instructor, I. of Wight. Price 1s.—***Northern Allotment Holder's Guide.*** January, 1918. (Newcastle-on-Tyne: Northern Allotment Central Association, West Lodge, Walker.)

THE MARKET FRUIT GARDEN.

AFTER its first week, February was generally a dry month, and mild in temperature. Consequently the month was well suited for work on the land, including the digging of orchards. Rain fell on 10 days, amounting to only 0.95 inch. The comparatively high temperature has had a marked stimulus upon vegetation. The leaf-buds of Lilac, Deutzia scabra, Ribes sanguineum, the Gooseberry, and the Black Currant were bursting on the 25th, and the Elder leaf was one-quarter out. Snowdrops and yellow Crocuses were in full bloom on the 20th, while Pear and Plum fruit-buds were swelling on the 25th. These are indications of a somewhat early season, though some records have surpassed them, notably those of 1913 and 1916. Not a single Plum or Gooseberry bud has been found to have been eaten by a bird up to the time of writing, bullfinches being conspicuous by their absence from my orchards.

INDICATIONS OF FRUIT BLOSSOMING.

Pears, Plums, and Apples alike show a general abundance of fruit buds, and, whether we are to have plenty of fruit or not, there is promise of a good show of blossom. Unless a sharp check comes soon, blossoming will be dangerously early. Sugar being lacking for home-made jam, except by the comparatively small proportion of housekeepers who grow fruit, a half-crop of Plums will be better for growers than a whole crop, and probably the same may be said in relation to Gooseberries. It is much to be regretted that sugar for home-made jam should not be provided for housekeepers generally, even if this should involve a reduction of the quantity allowed to the great commercial jam makers. Poor people, even if they do not grow fruit, can often buy it cheaply, and then they can make it at half the price they have to pay in the shops, and much better jam, too. Now that butter is at a prohibitive price and margarine scarce, the poor rely on jam largely as food for their children, and might be helped to make it by being granted permission to buy the necessary sugar, instead of being driven to the shops for it.

THE KEEPING OF APPLES.

Never before have late Apples kept so well in my experience as they have kept this season. In the last week of February fruits of Bramley's Seedling were packed without finding more than about 1 lb. rotten to a bushel of 40 lb., while the proportion of fruit containing a surface rot-spot or two was only 5 lb. out of 45 lb., and such Apples were fit for use with no considerable waste. Newton Wonder and Chelmsford Wonder have kept equally well, and so have D'Arcy Spice, Pippin and Mannington's Pearmain. By the way, the occurrence of 4° of frost in my fruit room on one night in January obviously did no harm to the fruit. Someone, writing in this journal some time ago, expressed the opinion that Apples keep best if gathered before they are ripe; but my Bramleys and Newton Wonders were allowed to hang on the trees last autumn longer than usual. Moreover, I notice that extensive investigations carried out by the Ameri-

FIG. 47.—ILIOPEA SPECIOSISSIMA, THE WARATAH, SHOWING FLOWER HEADS AT AN EARLY STAGE OF DEVELOPMENT.

(See p. 104.)

can Department of Agriculture in reference to the cold storage of Apples led to the conclusion that the picking of either immature or over-mature fruit leads to early decay. Other conclusions are that Apples keep better in a temperature of 32° F. than in a lower temperature; that a delay of even two weeks between picking and cold storing often greatly reduces the keeping properties of Apples; and that carelessness in the handling of the fruit previous to storing is as much responsible for bad keeping as an unsatisfactory condition during storage.

Scaly Blotch and Apple Storage

Experiments carried out by me this season indicate that scaly blotch in Apples neither increases nor extends during storage. A number of extremely slightly blotched Apples were placed in a tray in October, and in the last week of February not the slightest development of the malady had taken place. In another tray 54 badly blotched Apples were mixed with 54 quite clean ones, and there was not a single instance of the disease having spread from the former to the latter. It is useful to know that there is no need of taking out for immediate sale every blotched Apple, when selecting for long keeping, though when space in the fruit-room is not sufficient for all the late keeping fruit that it is desired to store, of course, it is well to clear out the disfigured specimens. Apples have paid very handsomely for keeping this season.

No Prospect for Cob Nuts

It is impossible that even a fair crop of Cob nuts can be produced this year, if the condition of plantations generally is like that of mine. One may walk past twenty or more trees consecutively without seeing a single catkin in fully three-fourths of the space in my principal plantation. So far as they are available near by, the branches from wild nuts containing catkins have been cut off and placed on some of the Cob nut trees; but I think that the female blossoms were forwarder than the development of pollen in the cold catkins.

The portion of my Cob nut crop gathered after October 1 was stored, and kept till the latter part of February, the last lot being sent to market on the 27th. At the time of storing the husks were quite brown, the nuts of the last few pickings having mostly fallen off the trees from over-ripeness. Yet they wasted in weight nearly 25 per cent., all having been weighed when stored and when marketed. If the husks had been green, of course, the waste would have been greater still, though much of the loss was caused by the depredations of rats and mice. If I ever store Cob nuts again, they will be protected by small-mesh wire netting. Notwithstanding the waste, the nuts paid well for keeping; for, whereas the last lot sold before October made only 9d. per lb. gross, those kept till February made 1s. 2d. to 1s. 4d. gross, rail carriage, commission, and toll to come off in both cases.

Brown Rot in Figs

There is reason to fear that my hitherto prosperous little plantation of Figs has been nearly ruined by brown rot. Last month all the half-sized fruit which always grows after picking time, and dies off, instead of being clean and healthy, had assumed the "mummified" appearance characteristic of fruit destroyed by the worst of all fungous diseases of fruit. The Figs have been picked off and burnt; but in very many cases the stems below them were found to have withered, the disease having extended from the fruits to the stems. In such cases cutting back was necessary, and Fig trees are intolerant of much pruning. Another point of ill omen is that the tiny Figs which form at the bases of those which always drop off when they are healthy, and form the crop which ripens, have not developed at the bases of the mummified fruits, while, of course, they could not form on the withered stems that have had to be cut off. One very large tree in an out-of-the-way place, which was forgotten when the rest of the trees were attended to, is now thickly studded with "mummified" Figs, which are covered with mould.

Scab and Brown Rot on Apple Wood.

In pruning varieties of Apples subject to scab on the wood, and particularly Cox's Orange Pippin, it is found that a large proportion of last season's growths must be cut off in consequence of being covered with scab. There is also a good deal of brown rot on spurs of a few varieties, particularly Lord Derby, Domino, and Early Julyan, although the blossom trusses attacked by the disease were cut off in the latter part of May.

Women as Orchard Diggers.

Possibly it has been mentioned on a former occasion that, while women do the work of digging with forks in fruit plantations passably well, they make it very expensive. Before the war, and before wages rose materially, I used to pay 30s. to 40s. per acre to men, the latter price where Black Currants were spreading all over the ground, and impeding the work. The men used to earn 4s. to 5s. 6d. per day, and probably they would require higher piece-work rates now that wages are 25s. a week. But the women, who work an hour less per day than men, and get 15s. if they work all the week, have made the cost £3 10s. per acre.

Rival and Barnack Beauty.

I am obliged to the correspondents who have given testimony of their experience in growing these two Apples, which has been of a satisfactory character. *Southern Grower.*

ON INCREASED FOOD PRODUCTION.

WINTER SPINACH AND SPRING CABBAGES AT ALDENHAM.

Winter Spinach has done remarkably well in these gardens this season. We usually make four or five sowings, and all except one has been a complete success. The prickly-seeded variety is generally regarded as the most hardy, but I find no difference in this respect between other Winter Spinach, and our cold, heavy land cannot be regarded as a favoured one for this wholesome and useful vegetable. Frequently Winter Spinach is sown too early, with the result that if a mild autumn follows the plants suffer considerably. I have often found that sowings made as late as the first week in October give the best results.

The photograph reproduced in fig. 49 shows a bed of Harbinger Cabbages on a warm border in these gardens. The photograph was taken on December 31 last, at which time a large percentage of the heads were fit for cutting. The seed was sown at the end of July and the seedlings planted out early in September. Not a single "rogue" has resulted from the sowing. *F. Beckett, Aldenham House Gardens, Elstree.*

Fig. 48.—WINTER SPINACH AT ALDENHAM HOUSE GARDENS.

LEEKS.

The Leek constitutes one of our most useful vegetables during winter and spring, and is, moreover, one of the hardiest of plants, no amount of frost seeming to do it any damage. To obtain good specimens seed should now be sown in pans or boxes, using a light, finely-sifted compost. Crock the receptacles well, place some rough turf or leaves over the drainage, and fill nearly to the top with the soil. Press the compost firmly, and sow the seed thinly on the surface, covering it with fine soil and water with a rose can. Place the pans or boxes in a warm greenhouse, and cover them with glass and paper to retain the soil moisture. The seeds will soon germinate, and when the seedlings appear, remove the glass and paper and stand the seed pans on a shelf close to the roof-glass. As the plants gain strength remove them to a warm frame and admit air on mild days to keep them sturdy. When the plants are large enough to handle they should be pricked out about 2 inches apart in boxes 2 feet long, 1 foot wide, and 5 inches deep. Carefully crock the boxes and fill them to the top with a compost composed of two parts loam, one part leaf soil, and one part old hot-bed or Mushroom-bed manure, with a little sand. A 6-inch potful of bone-meal to a barrow load of soil will also be beneficial. Mix the soil thoroughly, and press it firm in the boxes. An important point in pricking out is always to take care to lift as many of the young roots as possible, and in inserting them in the soil take care not to bruise them. As the

boxes are filled water the plants, and grow them in a warm frame close to the glass. Keep them close for a few days, but afterwards admit plenty of air, and about midday syringe them with tepid water. When the plants are strong enough they may be removed to a cold frame, covering the light with mats at night in case of frost. On warm days remove the lights for a time, and, with care in watering, the plants will do well until planting time arrives. The best Leeks are grown in trenches, which should be made ready during the winter. For a single row, 15 inches will be wide enough, and for a double row 2 feet. Mark out as many rows as are desired, and take out the soil 1 foot deep, placing this on both sides of the trench. Then shovel out the crumbs and place a good dressing of farmyard manure in the trench, thoroughly incorporating it with the soil. Afterwards put back some of the soil taken out to a depth of 4 or 5 inches. Fork over the ridges between the trenches, and leave all in a tidy condition. The time for planting varies according to weather conditions, but some date in April is usually the best time, provided the plants have been properly hardened. The trenches should then be raked over and made firm, taking care to do this during dry weather. Have the boxes close by, lift the plants with a trowel, and place them down the middle of the trench (if a single row) at about 1 foot apart. Plant firmly, rake over neatly when finished, and water in with a rose can. On warm days the plants may be syringed or damped overhead during the afternoon. As soon as they commence to grow blanching should commence, which is attained by gradually building up the soil from the ridges round the plants, placing a few inches at a time up as far as the leaf growth, and so on, until a stem of quite 2 feet is blanched. Before earthing up is commenced, however, the trenches should be well watered with diluted liquid manure. Stiff paper or tin collars about 9 inches long are sometimes used, placed over the plants soon after they are put out, and drawn up every time the soil is put to them. As the work proceeds it is advisable to tie the foliage with a piece of raffia to prevent soil from lodging in the crown of the plants. When the final earthing up is finished the banks of soil should be made sloping, and patted down with the back of a spade, so that superfluous moisture from heavy rain or snow may not be retained. Those who have not the advantage of warm houses or frames need not despair of growing Leeks in this way if the directions as to sowing and planting are carried out. The seed will germinate quite well though more slowly, in a cold frame. The varieties differ in appearance. Those, such as Broad Flag and London, which have very wide, strong foliage, are reckoned the hardiest. Others, such as Lyon, Prizetaker, and International are narrower in the leaf and long stemmed. They are all good sorts to grow. *B. W. Thatcher, Carlton Park Gardens, Market Harborough.*

PARSNIPS.

A WELL-CULTIVATED plot of Parsnips provides much useful food, and this vegetable is deserving of a more extended cultivation. Early sowing is to be recommended, but there is still plenty of time to make preparations for sowing the seeds in deeply dug ground. In these times labour for very deep digging is difficult to find, but good crops may be obtained from land which has been dug in the ordinary manner without the trouble of double digging. Choose rich land and an open situation. The soil should be thoroughly broken with a fork, and when the surface has been made fine and level, sow the seed thinly in drills made 18 inches apart and one inch deep. Choose a calm day if possible for sowing the seeds, as they are light and easily carried away by the wind. Cover them lightly at once, and in doing this do not rake the drills, as this would disturb the seed. Slugs are often troublesome as the young plants are breaking through the surface, and must be kept in check by frequent applications of soot or lime, applied very early in the mornings, whilst the slugs are still feeding. When the seedlings are 2 inches high they should be carefully thinned to 9 inches or 1 foot apart in the rows, according to the nature of the soil. Very little attention is necessary during the summer beyond keeping the soil between the rows hoed. One great advantage in having a good plot of Parsnips in every garden is that is ensures a supply of nutritious vegetables in winter, when other crops may be destroyed by frost. *J. Dunn.*

VEGETABLES FOR FORCING.

Potatos grown in pots or planted out in the border in a cool house return a good yield. Roots 9 or 10 inches in diameter are suitable. They should be efficiently drained with potsherds and half filled with a compost of which the strong sound loam should be good, fibrous loam. One selected tuber may be just buried in each 9 inch pot and the soil well watered. The development of the plant will be fairly rapid. As growth proceeds top dressings of rich soil should be added until the pot is filled to within half an inch of the rim. Stimulants may be given in moderation; applied to excess they impair the flavour of the tubers. An application once a week is sufficient, and I commence giving the stimulant as the young tubers begin to swell. Sulphate of ammonia and dilute liquid manure from the farmyard are given alternately. Last year our Potatos were attacked by aphis. This pest spreads with astonishing rapidity, and I would suggest that if observed prompt measures be taken for its extermination. An approved insecticide or paraffin soft soap wash should be used as a specific. Potatos require much the same treatment in an inside border as those outside. The rows may be made a little closer, say 18 inches apart, and the sets put 10 inches asunder. No rainfall will reach them, therefore it is necessary to attend carefully to watering. Duke of York and May Queen are two good varieties for early forcing. French Beans are forced into early bearing in great numbers. The plants should be grown in pots 8 or 9 inches in diameter. The pots should have plenty of drainage material, and be half filled with good soil. Twelve or fourteen seeds may be sown in each pot, subsequently thinning the seedlings to eight. French Beans germinate rapidly in a temperature of 65° to 70°. At all stages of growth they require an abundance of moisture. The atmosphere should also be kept humid, except when the plants are in bloom, but a moist atmosphere at that stage would militate against a good "set" of pods. Top dressings of equal parts fibrous loam and well-decayed manure should be applied as needed. After the pods have set and commence to swell the roots should be given weak liquid manure and soot-water, applied alternately. Red spider is a great pest of French Beans, and measures should be taken to destroy the insect as soon as it is detected. Fumigation on every other night for a few nights will usually destroy red spider, and syringing twice a day is a good insecticide to use. Sutton's Superlative and Osborne's Early Forcing are two excellent kinds for forcing.

Peas may be sown in pots just at once for planting out the third week in March. Boxes 1 yard long and 9 inches wide are much used. The bottom boards should be cut to fit to slide out when planting; the plants set this way receive only a slight check when they are planted. The seed will germinate freely in a cool house. Any of the early varieties are suitable. Broad Beans raised in this manner come into bearing much earlier than those sown in the open. *Geo. H. Copley, Horton Park Gardens, Bradford.*

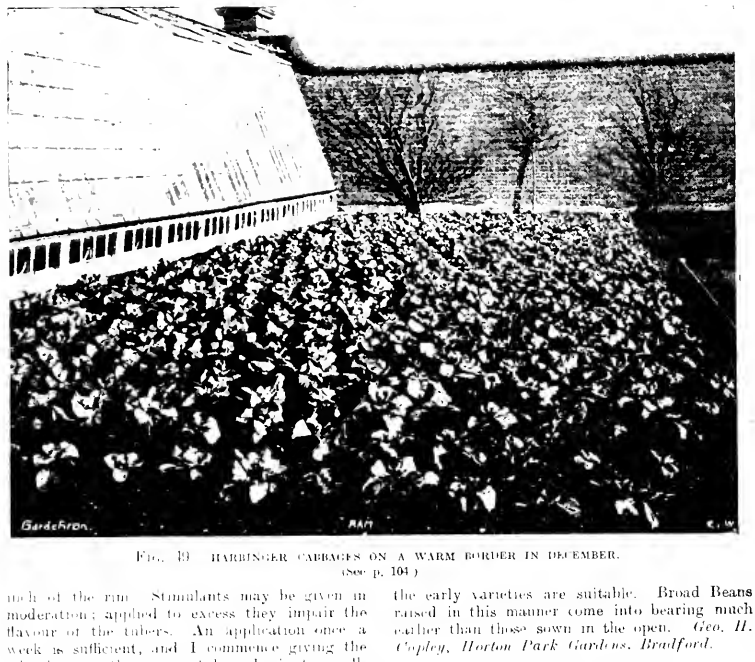

FIG. 39.—HARBINGER CABBAGES ON A WARM BORDER IN DECEMBER. (See p. 104.)

THE POTATO CROP.

THE Food Production Department's Commissioner for the Lincolnshire, Rutland, Nottinghamshire, and the Soke of Peterborough area sends some extremely interesting particulars supplied by leading local agriculturists as to the cropping of their holdings in the arable land part of his district. The figures with respect to 9,870 acres of land in the three estates concerned show that 2½ per cent. only of the land is now pasture, the whole of the rest being, or about to be, placed under cropping. In reply to questions as to what progressive farmers had done by way of altering their methods to produce the maximum amount of essential food crops (cereals and Potatos) Messrs. W. Dennis and Sons wrote: "Since war broke out we have broken up and converted into arable approximately 1,000 acres of grass. Our cropping under Barley has been considerably reduced in favour of Wheat. Oats have also been cut down, but

not to the same extent, and again in favour of Wheat. The cultivation of Onions is an innovation. Mustard for seed has been cut out entirely. Flax is a new departure."

In the eastern Potato-growing districts farmers have begun to draw out the ridges, and unless the weather should change for the worse planting will begin shortly.

The acreage of well-established pasture land and of old grazing land in this area ploughed up for Potatos is stated to be very large. The tractors are ploughing a great deal of grass land 10 inches deep, and the latest model steam cultivators, working on land belonging to the Ecclesiastical Commissioners, are ploughing four furrows each 14 inches deep and 18 inches wide in many fields. These cultivators are reported as leaving the loam in perfect condition for the drawing out of ridges with the Potato plough, the turf being completely buried and a strip of ground 2 yards wide turned over at each journey.

ALLOTMENTS.

THE average increase in the number of new allotments for the four weeks ending February 16, laid out under the Cultivation of Lands Order by local authorities, was at the rate of about 10,000 plots weekly. These figures, however, take no account of the large number of new allotments provided by private arrangement.

MUNITION WORKERS' ALLOTMENTS.

BY arrangement with the Food Production Department, the Ministry of Munitions has undertaken to communicate with all munition factories and to recommend that steps shall be taken by the managements to secure land for cultivation by the munition workers. The produce of the allotments, it is proposed, shall be available for the munition canteens.

ALLOTMENTS IN SCOTLAND.

THE demand for new allotments in Scotland is still on the increase, and public bodies are endeavouring to meet it with praiseworthy activity. In Glasgow and Edinburgh many new allotments are being asked for and provided. Hawick Food Production Committee has acquired additional land, for which they have between 70 and 80 applicants. Dumfries Town Council has also secured more ground, and had upwards of 70 applicants; while the neighbouring burgh of Maxwelltown is also adding considerably to its allotments. Lord Elphinstone has offered a piece of land to the mining village of Elphinstone for allotments.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

IRIS ROSENBACHIANA (see p. 75). — Mr. Dykes has adopted what appears to be a satisfactory way of growing Iris Rosenbachiana, *i.e.*, in a frame, closed in summer, but open in winter until the flowers appear. I presume the frame is kept closed until danger from late frosts is over? In the open, frost is often destructive to this Iris. By the way, does Mr. Dykes find much variation in the colour of his seedlings? Imported plants vary considerably in this respect. *S. Arnott.*

UNDESIRABLE APPLES (see pp. 66, 91). — I agree with Mr. Molyneux that there are far too many varieties of Apples. In his list of condemned sorts there are three or four I consider worth a second thought: King of the Pippins is one. The tree is a small grower, taking up but little room, and when grown on a good loamy soil the fruit is of the best quality, its crimson colour next the sun, chrome-yellow on the shade side, and firm yellow flesh are all desirable qualities. The variety, however, is very poor on some soils. Bess Pool has two faults: The tree takes a long time to fruit, and it requires a lot of room; but it has proved to me one of the most useful Apples in season from October to April. The fine, healthy foliage, clean, smooth wood, and handsome crimson-covered white-fleshed fruits are all points in its favour. Is Mr. Molyneux sure that in some districts Mank's Codlin is not required? The fruits are in season when there are plenty of other Apples, and the skin is very oily. My trees of Hawthornden fruit every year. I admit that the variety is subject to brown rot in some places. May I suggest that Mr. Molyneux add Hoary Morning and Rosemary Russet to his list? Lemon Pippin is very poor in quality, but the tree fruits well in some places, and is a late variety. Is it possible to get a census from, say, fifty districts, giving a list of the best twelve to twenty sorts from large and small gardens, nurserymen, and market-growers? I would willingly take two districts and find out the sorts that pay best. *Pome.*

—— Mr. Molyneux's note in reference to the elimination of useless varieties of Apples suggests the desirability of reducing the number of varieties of certain vegetables, such as Peas. We owe much to the firms engaged in the raising of new varieties in that they have been mainly responsible for the great improvement in the cropping capacity and qualities of our vegetable and fruit crops. It would, however, be an inestimable boon to the food producer if in this progressive introduction of new varieties of superior degree, a corresponding elimination of presumably superseded sorts was effected. An organisation for the testing of new varieties is needed, and at the same time proscribe worthless and too-much alike sorts. The R.H.S. has done something in this direction, but the great defect of their work is that their trials have been conducted at one centre only. Furthermore, their power is only of a moral or suggestive nature. Tests would have to be instituted with due regard to the behaviour of any variety under the various soil and climatic conditions existing, for instance, in England and Wales; and it is here that I wish to show the necessity of such a searching test by reference to Mr. Molyneux's condemnation of Domino. This Apple is certainly inferior in size when compared with Early Victoria and Lord Grosvenor, and may be even slightly inferior in quality, but here in the North of England it proves one of the most consistent of croppers, and exhibits a remarkable freedom from canker when grown in cold, clayey soils. With regard to the other varieties he mentions, I would plead only for King of the Pippins and Duchess's Favourite, which I include in the very few dessert sorts that are a success. *Chas. Watts Mayhew, Northumberland County Horticulturist.*

SOCIETIES.

ROYAL HORTICULTURAL.

TRIAL OF LEEKS.

THE following awards have been made to Leeks by the Royal Horticultural Society after trial at Wisley:—*Awards of Merit:* Champion, sent by Messrs. Dobbie and Co.; International Prize, sent by Messrs. Dobbie and Co.; Prize-taker, sent by Messrs. Sutton and Sons; and Royal Favourite, sent by Messrs. Sutton and Sons. *Highly Commended:* Improved Musselburgh, Large Early Poitou, Large Rouen, Renton's Monarch, and The Lyon. *Commended:* Giant Wonder.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 21.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. J. Bolton, D. A. Cowan, J. C. Cowan, J. Cypher, A. G. Ellwood, J. Evans, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, J. McNab, W. Shackleton, H. Thorp and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cattleya Snowflake Gratrixiae (labiata alba × Dusseldorfi Undine), a well-formed white flower with canary-yellow markings in the throat; *Odontoglossum crispum Trojan*, both from S. GRATRIX, Esq.

Odontoglossum Lawre-crispum (Lawrenceanum × crispum), bright yellow with crimson spots; *Odontioda Dorothy (Oda. Vuylstekei × Odm. crispum)*, exhibited by P. SMITH, Esq.

Odontioda Xeres (Odm. elegans × Oda. Charlesworthii), a large, chestnut-red flower, with broad, flat lip, from Col. Sir J. RUTHERFORD, Bart.

O. Diana Hamilton (Cochlioda Noezliana × Odm. amabile), shown by J. H. WALKER, Esq.

Miltonia Venus (rexillaria × Phalaenopsis), from Messrs. CHARLESWORTH AND CO.

AWARDS OF MERIT.

Odontoglossum ardentissimum Tiger, Lycaste Bessie Brown, Cattleya Trianae Mooreana, and Dendrobium Ophir (nutcum × signatum), exhibited by S. GRATRIX, Esq.

Odontoglossum highfieldense (Harryanum × Vuylstekei), from R. ASHWORTH, Esq.

GROUPS.

Large Silver Medals were awarded to R. ASHWORTH, Esq., Newchurch (gr. Mr. Davenport), and Messrs. CYPHER AND SONS, Cheltenham, for collections.

LINNEAN.

AT the meeting of the Linnean Society held on the 21st ult., a paper by Mr. William B. Brierley, entitled "Experimental Studies in the Specific Value of Morphological Characters in the Fungi," stated that in all systematic treatment of the fungi there is implied constancy of morphological characters, and particularly of the size and shape of the mature reproductive bodies or spores. An experimental study of the specificity of these criteria is in process, the work being carried out primarily upon the fungus Botrytis cinerea. This species is contained in the "Polyactis" group of the genus, and the species in this group are separated partly by reason of their different hosts, but more critically by minute differences in the branching and septation of the conidiophore and by the size and shape of the spore.

The published spore-measurements of Botrytis cinerea show a singular lack of uniformity (Marshall Ward on Lily, 20-25 $\mu \times 15\ \mu$; Lorrain Smith on Gooseberry, 8-11 $\mu \times 4\text{-}6\ \mu$; R. E. Smith on Lime trees, up to 30 μ; etc.), and during the present investigation observations of the mode-spores of Botrytis cinerea growing upon different hosts, or separate infections of the same host, have shown that this variation in size and shape is a very marked feature of the fungus (on Alder twig mode-spore $3\ \mu \times 2\ \mu$; on Tomato fruit $10\ \mu \times 10\ \mu$; on Onion bulb $6.5\ \mu \times 3.5\ \mu$; on Lily $14\ \mu \times 10\ \mu$; etc.).

Pedigree cultures derived from single spores of the fungus growing upon different hosts were made, and these were used as the basis for all critical experimental work.

Botrytis cinerea developing upon living Cabbage possesses a certain mode-spore. If this strain be inoculated into Tomato fruits, the mode-spore is different in size and shape; and a third host produces a third mode-spore. The fungus growing upon Onion bulb shows a characteristic mode-spore, and if this strain be inoculated into Cabbage, Tomato, etc., the mode-spores differ from each other and from those produced by the first strain. Variations and combinations of these experimental inoculations were carried out with strains of different origin, the substrata being living plants, steamed tissues, and synthetic media, and the sizes and shapes of the mode-spores were recorded. It became evident that the species Botrytis cinerea is not "ungeheuer variabel" (Lindau), but that its apparent variability is due to the fact that it contains a great number of "elementary species" or "Jordan's species" which are morphologically distinct. The size and shape of the spores of the "elementary species" show two kinds of variation: (1) normal variation, which is always present upon whatever host or substratum the fungus develops, and the range of which is characteristic of the elementary species; and (2) "modal variation," which is the variation in the size and shape of the mode-spore, and is directly and constantly induced by the particular substratum. In nature the "elementary species" are usually found upon par-

ticular hosts, but they readily attack other plants and, when growing saprophytically, are omnivorous.

The size and shape of the spores of the fungus growing in nature are therefore not morphological constants but resultants of the strain of the fungus and the substratum upon which it is developing; and the only method of critically identifying the particular elementary species present is to isolate it in pure culture and obtain its "modal variation" upon a series of standardised media.

The presence of modal variation in the size and shape of the spores has been ascertained in three species of Penicillium and one species of Stysanus which have been investigated, and it is suggested that it may be of general occurrence in the fungi.

Other morphological characters of Botrytis cinerea—rapidity of growth, minute details of physiology of parasitism, septation and branching of conidiophore, structure of sclerotia, etc.—are being investigated, and are yielding results of a similar nature, and it appears not improbable that the present species in the Polyactis group of the genus must be regarded as host forms of elementary species of Botrytis cinerea.

"Modal variation" is not due to physiological starvation or repletion or other known nutritional conditions resulting from various substrata. It is suggested that it may be due to some growth-stimulant or accessory food-factor, which is constantly present to a different degree in different food-substrata.

CROPS AND STOCK ON THE HOME FARM.

STORING LAND.

STORING is a term used to denote cross-ploughing, which disintegrates the particles of clods, disturbs grass or other weeds and exposes the soil to air, wind and frost, making it all the more friable when the time comes for sowing whatever crop is intended to be grown. During dry, frosty weather no opportunity should be missed in storing land intended for Potatos, Mangolds, or Spring Corn, and especially Barley that is to follow Wheat.

SCREENING OATS FOR SOWING.

It is wise to screen home-grown Oats before sowing after coming from the threshing machine, to remove the small corn. Seed obtained from a seedsman does not require such attention, as the seedsman removes all weakly corn. I fail to see how small, immature Oats can produce a plant as strong as a larger, more solid seed. In screening there is no loss whatever, because the rejected Corn can be used as food for horses. I treat Wheat for sowing in the same way, as evenness of seed gives a more even and desirable crop.

SUNFLOWER SEED FOR FODDER.

IN view of the shortage of food for poultry, Sunflowers might be made more use of for this purpose, and also for pigs. If the seeds are matured they contain much oil, which is valuable when the seed is crushed and added to other food, and especially for pigs. Sunflowers require not only a long season of growth to mature the seed properly, but much sunshine at the ripening stage. If only a few plants are grown the plants could be advantageously raised under glass if even a cold frame only is used six weeks would be gained by that method, and with a reasonable amount of sunshine success might be anticipated.

It is wise to grow a tall and a dwarf variety in the same row, as the plants would then receive more regular sunshine than if all were tall plants. Giant Russian, referred to on p. 74, is the best variety. If seeds of that variety are not procurable the American Giant form should be planted. Deeply cultivated and well-manured soil is necessary to ensure success. Deep autumn ploughing would be an advantage, and ploughing again in the spring to obtain a good surface tilth. Ample space is required for the plants. The rows should not be closer than 3½ feet, and the plants thinned to 15 inches apart in the rows. Dibbling the seeds 2 inches deep, two in each hole, is the most certain way of sowing, and the seeds are then more out of the reach of rooks than when drilled in shallowly. If a large area is to be sown—say several acres—and the soil in good tilth, then drilling, under favourable conditions, would be preferable.

Keep the plants free from weeds and, as the flower-heads form, thin them to four of the strongest on each plant. In a small plot the application of liquid manure to the roots during dry weather would be a distinct benefit to the plants. In a field crop sprinkling superphosphate or sulphate of ammonia on the surface soil occasionally would aid growth, and especially if the surface soil is occasionally stirred to enable the rain to wash the stimulant freely amongst the roots.

JERUSALEM ARTICHOKES FOR PIGS.

WITH the diminishing quantity of cereals, pig-keepers must provide substitutes on which pigs can be kept a considerable part of the year with but little meal.

The Jerusalem Artichoke produces a large crop of tubers with good cultivation, and the cooked tubers provide much desirable food for small pigs, supplemented by house scraps and a small quantity of meal. Sows appreciate the tubers in a raw state. Too often this Artichoke is allotted out-of-the-way corners where it grows for many years, even without replanting. Plants grown in such unsuitable situations cannot produce heavy yields of tubers, but well manured and deeply cultivated land of any kind in the open will grow large crops of this Artichoke. The tubers should be planted at once in rows made 2 feet apart, allowing a space of 15 inches between the plants in the rows. As planting proceeds sprinkle superphosphate over the tubers to aid their growth.

The subsequent treatment consists in keeping the land free from weeds and stirring the surface two\[illegible\] during growing weather.

An error crept into last week's remarks on the subject of the prices of pigs. With regard to the sow and young pigs sold for £23, it should have been stated that the young ones numbered nine, and were three weeks old. Further, the bacon sow sold by weight realised £22, not £25 as stated.—*E. Molyneux.*

Obituary.

G. ALLARD. *Le Bon Jardinier* announces the death of Mr. G. Allard, vice-president of the French Dendrological Society. Mr. Allard was widely known by reason of the fine arboretum which he established at la Mardeverie, near Angers. This collection is an important one, and particularly from the point of view of trees and shrubs which do well in the west of France. The arboretum occupies about 17 acres, and was planted entirely by Mr. Allard, who undertook the work after a series of voyages of investigation in the Mediterranean region, including Northern Africa. The first plantations were made in 1865, and the Sequoias in the collection date from that year. The important collection of Oaks was planted in 1876, and comprises more than 100 species, varieties and hybrids. Beside these trees the arboretum contains a rich collection of Camellias and of cultivated Vines which fruit in the open. Among the most interesting and rare specimens noticed by Parde in a report published in 1904 mention may be made of Fitzroya patagonica, Libocedrus tetragona, Picea Morinda, Quercus crassipes, Sequoia gendalis (20 metres high), Picea Omorika pendula, hybrid Chestnuts (Castanea × mollissima and Castanea × regalis), Robinia dubia (Pseudacacia × viscosa), Fraxinus globosa × pennsylvanica, and hybrid Oaks. Unfortunately no catalogue of the arboretum has been published, but there is a certitude that the arboretum will be continued, for Mr. Allard has bequeathed his estate to the Pasteur Institute (Paris), with the condition that the Institute shall provide for the maintenance of the collection at la Mardeverie.—*L. M.*

MARKETS.

COVENT GARDEN, March 6.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—ED.

REMARKS. There is a shorter supply of flowers this week, and the prices of Lilium longiflorum and Richardias (Arums) are increased. Owing to rough weather there were no flowers from Scilly and Guernsey during Friday and Saturday last, but fairly large consignments are being received this week, chiefly consisting of Daffodils, which are arriving in good condition. Tulips are increasing in quantity as well as quality, there is now a good selection of Darwin Tulips of various shades. Roses are increasing daily in numbers, such varieties as Ladylove, Sunburst, and Richmond being offered in excellent condition. Prices are on the down grade. Lily-of-the-Valley continues plentiful in supply, and daily consignments are reaching the market, chiefly from our

grower. Little change is noticeable among the consignments of French flowers. White Narcissus appears to be getting over, but more white Stock is arriving. Anemones are cheaper.

— navel, per case	50 0– 55 0	
— Tangerines, per 100 ...	1 8– 0 —	
Strawberries, forced, per lb.	15 0–25 0	
Walnuts, kiln dried, per bag ...	52 0–1.0 0	

REMARKS. Supplies of English selected Apples are now very limited, but there is still a quantity of inferior samples on offer. Forced Strawberries are arriving daily in limited quantities. The market is well supplied with English Grapes for the season of the year, and fairly large quantities of Almerias (Spanish) are available. Forced vegetables are now commencing to increase daily in quantity. Vegetables and roots (outdoor) are fairly plentiful, but buyers complain that, owing to the shortage of meat, vegetables are selling cheap. *E. H. R., Covent Garden Market, March 5, 1918.*

CATALOGUE RECEIVED.

Foreign.

PETER HENDERSON & Co., 35-7, Cortlandt Street, New York.—Seeds.

HENRY A. DREER, 714-6, Chestnut Street, Philadelphia, U.S.A.—Seeds.

ENQUIRY.

CAN your readers give me any information how to cement coat wire nails: also what kind of cement to use for nails in Apple boxes for market. *L. B.*

ANSWERS TO CORRESPONDENTS.

BANKSIA ROSE: *L. W. C.* Beyond thinning the weakly growths and removing dead shoots, no further pruning is necessary.

CELERY TRENCHES: *L. W. C.* Take out a trench 1 foot wide for one row of Celery, or 18 inches for a double row, and 12 inches deep. In the bottom of the trench place half decayed manure to a depth of 6 inches and cover the manure 3 inches deep with soil from the side of the trench. Set the plants out in the middle of April 10 inches apart, and water them freely in dry weather to promote freedom of growth.

CONIFERS: *Constant Reader.* Most of the standard works on Coniferæ, such as *Veitch's Manual of Coniferæ* and *Gordon's Pinetum*, are out of print, but copies are sometimes listed by second-hand booksellers. *Trees and Shrubs Hardy in the British Isles*, by W. J. Bean, in two volumes, contains descriptions and illustrations of many Coniferous trees. It can be obtained from our publishing department, price £2 2s. 10d. post free.

HOLLY TREE: *T., Ruthett.* The Holly is one of the most uncertain trees to berry, and a plant growing by itself is less likely to fruit than where it is in association with others. Try budding your plant in August with buds from a tree that fruits well and regularly: this has been known to answer in many cases, though it is not an absolute certainty.

LEAVES FOR EXAMINATION: *T. G.* Such scrappy specimens as those you send are insufficient for correct identification of the cause of their condition, especially as you do not even mention the names of the plants. Some have been eaten by an insect, probably a cockroach, which has gnawed off the epidermis of the leaf, leaving dead patches. What appears to be the leaf of a Chrysanthemum is attacked by a leaf-mining insect. In the case of the Chrysanthemum remove all badly affected leaves and burn them, and spray the plants with Quassia extract or some other insecticide to prevent the female insect from laying her eggs on the leaves. The other plants should either be dipped in or sprayed with an insecticide.

MOLES IN THE GARDEN: *E. C.* We know of no other way of destroying moles than by the aid of spring traps, the japanned ones being preferable. Set the traps in the more recently made runs, just before rain, say in the evening, and inspect them on the following morning. The traps should be sunk well into the newly made burrows. As new upheavals of soil are noticed add more traps to these runs. By continuing to set the traps there should be no difficulty in clearing a garden of these pests.

MUSHROOMS OUT OF DOORS: *J. M.* Collect as much fresh stable litter at one time as possible, shake out the longest litter and dry it for covering the beds where clean straw is scarce. Place the manure in a compact heap to ferment, and turn the heap two or three days afterwards, and again every third day, four times in all, or until the rank gases of fermentation have passed off. An open shed is the best place in which to prepare the material, and the size of the bed will depend on the quantity of dung available. The ridges should be made in a favourable position from north to south, and be sheltered from north and east winds. Ridges 2 feet 6 inches to 3 feet wide, and the same in height, are the most suitable size. From July to January is the best time for making Mushroom beds in the open. Make the ridge firmly, placing the dung in layers of, say, 15 inches, and treading it well until the desired height is obtained. Cover the ridge with litter to protect it from rains and to retain moisture in dry weather. Mats or tarpaulin sheets may be used for covering the bed in winter. Place sticks in the ridge in several places, and examine them to ascertain when the heat has declined to 75°, which is a safe temperature to spawn the bed. Break each cake of spawn into twelve pieces and insert the portions 9 inches apart and 3 inches below the surface. After three or four days examine the ridge to make sure that the temperature of the bed is not more than 75°. If everything is favourable cover the ridge with 2 inches of fine soil in a medium state of moisture, and pat it firm with the back of a bright spade. Again cover the bed with litter in thickness according to the season. It is not necessary to examine the bed for a month, when it should be again covered with fresh litter. Sometimes the Mushrooms will appear in a month or six weeks, but patience is needed; if the beds are made properly, and good spawn is used, a crop will appear sooner or later.

NAMES OF FRUITS: *Mrs. E. P. R.* Mère de Ménage.—*F. W. O.* 1, Lady Lennox; 2, Normanton Wonder; 3, Flower of Kent; 4, Harvey's Wiltshire Defiance; Pear decayed.—*W. P. F.* Wheeler's Russet.

NAMES OF PLANTS: *F. W. O.* Eupatorium sp.—*W. C. Maiden.* Oncidium splendidum. The plant thrives best in a basked or pan suspended from the roof-rafters at the cooler end of the intermediate house. It requires the same temperature and similar treatment as Mexican Laelias, and may be grown with them wherever they are thriving satisfactorily. The species may also be grown in a pot on the staging in a well-ventilated situation. The value of a good specimen is from ten to fifteen shillings.

PASSION FLOWER: *T. J. H.* For growing out-of-doors Passiflora coerulea is the best species; the variety Constance Elliott has white flowers. Those you mention are too tender to be grown in the open all the year round, though they will succeed during the summer, but our winters are too damp as well as too cold for the plants. Passifloras may be obtained from most nurserymen.

PEACH TREES: *C. J. C.-S.* If the Peach trees are in flower it is too late to fumigate or syringe them with an insecticide strong enough to kill black aphis. Mix some Quassia extract and apply it to the affected shoots with a brush until a week or ten days after the fruits have set, then syringe the trees with the specific on alternate days and occasionally afterwards.

SLUGS: *T. J. H.* A narrow ring of sawdust round the plants is one of the best means of protecting them from slugs. The sawdust sticks to the creatures and renders them unable to move easily, though, of course, it does not kill them. Sawdust is easily obtainable, and can be renewed when it becomes too wet to be of use.

VINES IN POTS: *Mr. F. N.* Not much harm would be done in removing the stronger roots and transferring the vines to larger pots. The best method at this late date is to prepare a rich bed for the vines as in former years, and feed the roots with stimulants during the summer, repotting them into larger pots earlier next season.

WAGES FOR SKILLED WORK: *L. M. C.* For the kind of work you mention 1s. per hour would be a fair price to pay; such work would not last long. From 7 a.m. to 5.30 p.m., with half an hour for breakfast and one hour for dinner, would be a fair working day. A jobbing gardener who is known to be practical, thoroughly understanding such duties as pruning and the general routine of managing all kinds of fruit trees, would be worth double the wages of an unskilled man.

WHITE FLY IN GREENHOUSE: *C. P.* The small white fly you mention is probably a species of Aleyrodes. Since you say you have tried the ordinary fumigating compounds without success, you might try hydrocyanic acid gas, but as it is exceedingly poisonous the fumigation must be done with the greatest care. The house should first be carefully measured, as the proportions to be used depend on the size of the building. They are as follows: Sodium cyanide, ⅛ oz.; phosphoric acid, ¼ oz.; water, ½ oz., for each 1,000 cubic feet. Be careful to obtain perfectly pure acids, and to use the exact proportions given. At the strengths given the plants will not be damaged; one fumigation is sufficient to kill green fly, and will probably be adequate for white fly. You may, however, double the quantities of the ingredients, in which case it is possible that the young foliage of some of the plants may be injured. The best results are obtained by fumigating the house at dusk, and leaving it closed until the following morning. The plants must be perfectly dry, and the temperature should not exceed 60°. Do not place the acid in a metal vessel, or in paper, and drop the cyanide into it direct. During fumigation keep the house tightly closed, leaving no chink whereby the gas could escape, and after it is opened care must be taken to see that no one enters it until it has been thoroughly ventilated. For fuller particulars see *Gard. Chron.*, July 25, 1914, p. 65.

LILIES IN 1917.

RETROSPECTIVELY, the years as they rush on are, in the main, very much alike from the gardener's point of view; there are differences, of course, but they do not amount to much—a fine and dry autumn one year, an abnormally wet one the next, and so on, the effect being seldom sufficiently pronounced to make anything more than a hazy picture on the mental camera. But once in a while there comes a season so different from the rest that it makes for itself a red-lettered place on life's calendar and is not forgotten.

There have not been many such seasons in comparatively recent times, and a glance through memory's diary for five-and-twenty years reveals but a couple—the great frost of 1891 and the tropical summer of 1911. Men of riper experience than the writer can lay claim to will no doubt recollect the severe winter of 1860, when the common Laurel was killed outright, and gardening people do not need to be told what that implies.

To this short tally of memorable seasons the winter of 1917 should certainly be added, not perhaps because of an exceptional degree of cold, but by reason of the inordinate length of it, and the cruel grip which frost and polar winds combined to keep on spring, foiling it week after week in remorseless spirit, and giving way to the sun so grudgingly that in true Canadian fashion May was almost on the stage before there was the sign of a nest or a vestige of green in the hedgerows.

But though the experience was an inexpressibly disagreeable one to a generation of gardeners accustomed to a long series of gentle winters, the crowding of March, April, and May into one had its compensations, and the astonishingly beautiful transformation scene the sun set for us when at last winter had been finally worsted was by no means the least of them.

During the early months of the year everything, in horticultural parlance, was kept in its place, and plant life, frost-bound and chilled to the core, made none of those false starts—begotten of the union of the sun with the soft south wind—that in more normal seasons almost invariably lead to subsequent wailings.

Hence it came about that February, March, and even April passed without so much as a sign of a Lily thrusting through the crust of the earth, and when May was ushered in on the wings of the blackest of north-easterly winds one felt that winter had been prolonged beyond the limits of human patience.

We islanders are so used to the tricks of that incomparable conjurer the clerk of the weather that he is seldom able to spring a surprise upon us; we may, therefore, acknowledge the more ungrudgingly that with the coming of May, the sudden transition from winter to summer may be laid to his credit as a great coup. The magician waved his wand, and in a trice the earth was instinct with budding life. All the pent-up energy of the early months of the year burst forth and made a garden picture of inexpressible beauty.

Chaos it was, in truth, viewed from the standpoint of the regulation horticultural time-table, but chaos of inestimable beauty.

Lilies shared in the general rush to the sun, and managed it to such purpose that in five weeks they had made more growth than they usually put forth in twice that time. At the beginning of May no gardener could have supposed that by the middle of the following month the normal order of things would have been re-established. Yet so it was with Lilies, and a little later on, cowed by week after week of cloudless skies, they had not only made up all leeway, but were rather in advance of their usual dates. Had the promise of midsummer been fulfilled one could have written ungrudgingly of the past season, but the comparative absence of sun in July and an overplus of rain generally had the inevitable effect of spoiling a Lily year that promised remarkably well.

Not one of the European or Asiatic species showed the least trace of the harsh treatment meted out to them during the long winter; but the Lilies of the Western United States had obviously received a severe check, and were unable to throw off the effects of it. In the majority of cases this took the form of stunted growth and paucity of flower; but some few species, such as Kelloggii, maritimum and occidentale, found themselves unable to make more than a meteoric appearance, retiring below ground in rather precipitate fashion after a few weeks of half-hearted existence. At the time of writing, all these Lilies are well above ground, so evidently no permanent harm has come to the bulbs.

An oversight by which a basket of bulbs of L. Sargentiae and Willmottiae came to be left in the open last winter, unprotected and exposed to the unspeakable rigours of the first five weeks of the year, justifies the conclusion that these two species are frost-proof, and incidentally opens a channel for reflection. When remembered and retrieved, the bulbs were mere lumps of ice, and must have been in that state for some time; yet in due season they threw up splendid stems and flowered remarkably well—better, in fact, than others that had been kept out of reach of the frost. A more noble Lily in every way than L. regale, L. Sargentiae has still to prove itself such a good garden plant as the former. Cold has evidently no bearing on its well-being, but early winter rains have, and cultivators of this beautiful plant would do well to keep the bulbs as dry as they can while they are dormant from October till about the middle of January. The species needs as sunny a place as can be found for it, and soil from which lime is absent. L. Sargentiae is one of the most delicately fragrant Lilies we have, and in that respect takes after its cousin, L. sulphureum.

It is pretty generally known that, except in the case of a few species, such as L. pardalinum, croceum, Martagon, pyrenaicum, and one or two more, Lilium seed does not usually germinate if left to arrange matters as best it can, so that colonies of self-sown plants are by no means common. Those versed in such matters lead us to suppose that refrigeration has a beneficial effect on the germination of many seeds, and we may perhaps look in that direction for an explanation of the wonderful crop of self-sown Lily seedlings that was evident on every hand last summer, for the seed that fell to the ground in the previous autumn must have been frozen before the year was out.

Some of the Chinese species in particular were conspicuous in this respect, and the ground under plants of L. Willmottiae, Thayerae, and regale was green with the "grass" of innumerable seedlings. It was the same with the Californian L. Roezlii, and many of the European species, which, however, sow themselves pretty regularly.

It is not to be expected that many of these "windfalls" will survive to adolescence, for heavy toll is taken of such things by slugs, earwigs, woodlice, and the countless hosts of predatory insects that have somehow to pick up a living between dusk and dawn. A winter of exceptional severity seems to have no terrors for these creatures, for they were in unusual force last summer, and as the ranks of their natural enemies the birds were severely thinned by the cold, they were able to do even more harm than usual.

In connection with the germination of Lilium seeds, the following note from Mr. H. J. Elwes draws attention to a peculiarity, that is not, perhaps, so well known as it should be:—

> "In my monograph of the genus Lilium (1880) I stated, on the authority of Professor Duchartre that the seed of L. monadelphum does not show its cotyledons above ground. Lubbock, in his book on *Seedlings*, Vol. II., p. 577, writing of the Liliaceae, says that the cotyledon in this family is always aërial, and carries the seed up with it during germination. The late Mr. Wolley Dod stated that in this species this is not the fact, and I sowed a quantity of seed in the open ground some years ago with the view to testing it. These first appeared

above ground in the second season after sowing, but as slugs might have eaten off the cotyledons, I was not certain of the fact until now. In November, 1916, I sowed two pans of seed of this Lily, which have been kept in a cold frame facing north ever since, and are now (Feb. 25) just showing their first leaf above ground, six weeks or two months before the parent plant will [illegible]. An examination of these seedlings shows that the germination has been [illegible]. Though I could find no remains of the testa in the earth, and the [illegible] tiny bulbs prove that the [illegible] germinated last year. I shall be glad [illegible] whether this is the case in any other [illegible] Lilium."

Such a more helpful article begins to [illegible] the time of the year, and the right

of the Euhrion group, of which a good many examples are to be found in herbaria, generally tacked on to Orit misnamed and much misunderstood Lily, L. Browni leucanthum.

The connection between the Lily described under that name (*Bot. Mag.*, t. 7,722) and L. Brownii is indefinite, for though herbaria contain many specimens from Western China labelled "L. Brownii," the species has not yet been reported from that country, and none of the many so-called forms of L. Brownii collected there of recent years can be referred to it, the bulb of which is unique and unmistakable. The origin of L. Brownii is not known with certainty, and though the plant is cultivated in Japanese nurseries gardens, there is no record of it as a wild plant of Japan. It may possibly turn out to be a cultivated form of the Lily so magnificently named L. japonicum colchesterense, which is now [illegible]

that there is comparatively little difficulty in establishing colonies of Lilies raised from seed in this country, and L. Brownii is no exception to the rule. No doubt the fact that this species seldom if ever ripens seed in Great Britain has made the raising of one's own stock a little difficult, but nowadays, when seed of nearly every species is to be had, in one direction or another, by those who want it, growers should not have any trouble on the point.

Once established in her suitable conditions, L. Brownii can be relied upon to go on and flourish from year to year, for few species are more prolific in the production of offsets.

That fine hybrid, L. Parkmanii, seems to have appeared once more, having been regenerated by Mr. Hayward (*Gard. Chron.*, Sept. 1, 1917, p. [illegible]) and it is to be hoped may not be allowed to go out of cultivation again.

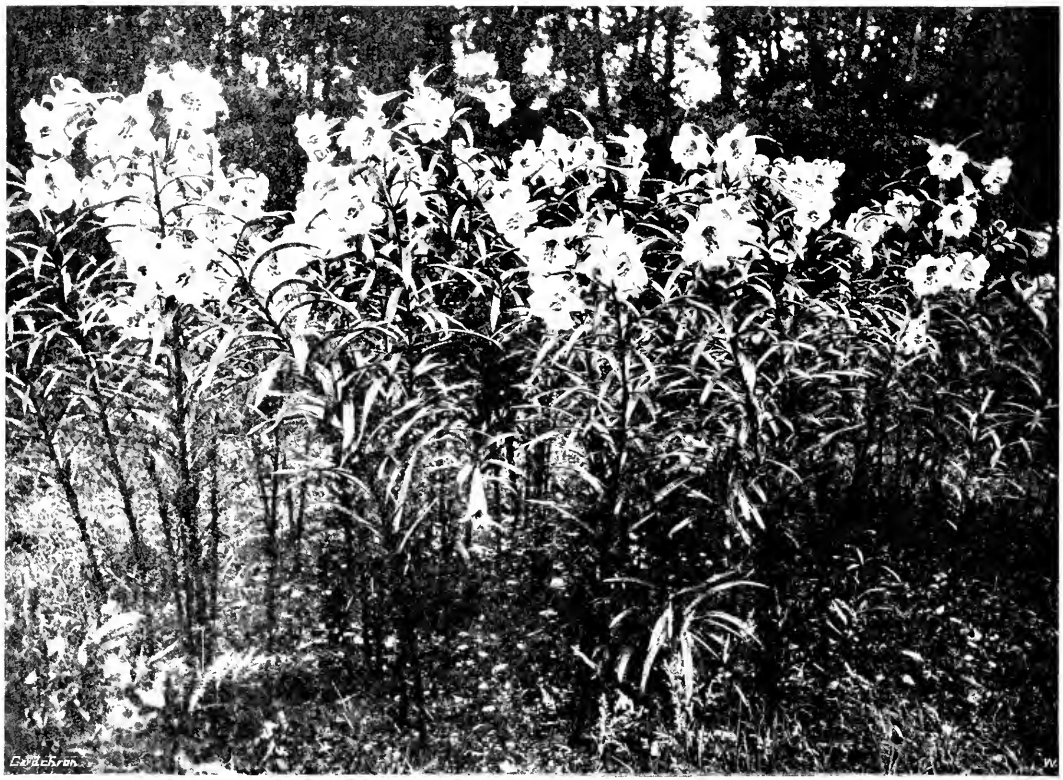

FIG. 50.—LILIUM BROWNII F. MACULATUM IN MR. [illegible]'S WOOD GARDEN AT HILLBROOK, BUCKINGHAMSHIRE.

ground development referred to by Mr. Elwes can be watched by anyone interested in the absorbing study of the meantime of plant life. Sometimes the seed of this and other species will lie dormant for a season, and it is not easy to [illegible] a strong explanation of this vagary. L. [illegible] takes the business of life in [illegible], and many species have flowered, [illegible] seed their race before it has attained the flowering stage.

So [illegible] is aware, nothing very new [illegible] Lilium species made an appearance [illegible] under the conditions prevailing [illegible] would have expected it to have been otherwise. From Messrs. Wallace a plant was received as L. Dalhousiæ, raised from seed received from Mr. Forrest, while Mr. Bowles sent a young flowering specimen of a Lily he had raised from seed sent home by Mr. Farrer from Kansu. This proved to be a species to be a native of Western China, as Mr. E. H. Wilson found it on Hupeh some years ago, and sent bulbs to the writer at the time. The bulbs of L. Brownii and the so-called varieties are as different as, shall we say, those of L. speciosum and Henryi. Though L. Brownii is not to be included in the list of species that will grow anywhere, the illustration (fig. 50) of a wonderful old colony of it in Mr. Yorke's wood garden at Hillbrook shows of what this fine Lily is capable when handled with sympathetic appreciation of its needs in the way of soil and location.

It is in the initial stages that would be growers of L. Brownii usually find themselves gravelled, and that is because, knowing no better, they rely on bulbs imported from Japan, which are as troublesome to establish as are all Lilium bulbs sent to Great Britain from countries afar off.

The writer has pointed out again and again

The cold winter seems to have suited L. speciosum remarkably well, and if only the weather in the late summer had been a little kinder, there would have been a magnificent display of this species. The photograph (fig. 51) shows an unusually fine flowering head of L. speciosum magnificum. *J. Grove.*

ORCHID NOTES AND GLEANINGS.

ODONTIODA ETHEL II.

At the meeting of the Royal Horticultural Society, on the 26th ult., Dr. Miguel Lacroze, Bryndir, Roehampton, showed as Odontioda Ethel var. Bryndir, a very pretty hybrid resulting from crossing Odontioda chelsiensis and Odontoglossum percultum. Messrs. Charlesworth and Co. had previously given the name Odontioda Ethel to a cross between Cochlioda

Norghana and Odontoglossum hastilabium, and Odontioda Ethel has also been exhibited by Messrs. Flory and Black. In view of the older plant having priority as to name, Dr. Lacroze's plant has been entered on the records as Oda Ethel H., following the precedent of Cypripedium Helen H., which was a duplicated name under similar conditions. Oda. Ethel H. is a specially attractive flower, the inner parts of the segments being densely spotted with orange-red on a light ground, the margins and outer thirds rosy lilac.

CYPRIPEDIUM BELTROILUS

MR. JAS. SMITH, Orchid grower to the Duke of Marlborough, Blenheim, Woodstock, sends a flower of Cypripedium Beltroilus, a rather curious hybrid between C. bellatulum and C. Thalia Lord Nelson (insigne Harefield Hall) interbreed raised at Blenheim, and now flowering for the first time. The dorsal sepal is white on the upper half and gamboge yellow on the lower part, with heavy blotches of chocolate brown changing to light purple in the smaller spots of the white area. The petals are 5 inches from tip to tip, 1½ inch wide, and show strongly the influence of C. bellatulum. The ground colour is yellowish tinged with rose and profusely spotted with claret red. The lip, which is larger than that of either parent, is pale yellow on the margin and unfolded side lobes, the surface being rose colour. The broad lower sepals are pale yellow with claret lines.

CONFESSIONS OF A NOVICE.

WHEN I read the leading article on the keeping of a garden in war time I experienced a thrill of satisfaction, for the programme and down therein is in essentials that which in the cloistered calm of my novitiate I had mapped out for myself. Everywhere in the borders and shrubberies I propose to plant Sunflowers, and this will, at all events, justify me in digging over the ground, which is thickly carpeted with two years' accumulation of Larch needles. I trust that British birds will refrain from their annual tricks and leave the seeds alone. Partly in desperation at the impossibility of obtaining manure except at a prohibitive price, and then with no prospect of getting it carted, and partly to self provide, I have already installed the piggery. We built the sty partly of old notice boards. It looks neat and trim, not yet occupied—and, facing the run, is a board stating the propitious sign, "This eligible residence to let." The trouble will, of course, be to obtain the offal or cake, but that trouble is, I believe, to be overcome by a licensed allowance for young pigs. I should have liked to run the pig on the extensive system, but this is a small place, and so perforce the pig must do the best it can with what offal we can give it plus household and garden refuse. The third oil producing organism, in addition to the pig and Sunflower—excellent as a sign for a wayside inn—is the goose, and if any of your readers knowledgeable in the raising of geese would give me a few encouraging hints I would willingly do my bit in the way of fat production by becoming a goose herd. Cobbett, in one of the early pages of his journal (*Rural Rides*), says of fat hogs at 7s. 6d. a score, the boot of profiteering was on the consumers' leg in those days, and we heard nothing about it that, fattened on Peas and Barley meal, they "may be called the very best meat that England contains." I shall try Peas on a piece of newly turned up grass land in the hope of obtaining a supply for the pigs, because I cannot help thinking, first, that Peas are a good crop to take on such ground, and second, that their richness in nitrogen ought to make it possible to do the animals sufficiently well with chat Potatos, poor Parsnips, Beet, and Artichokes from the garden. All these latter things are rich in starch or sugar, and if the pig cannot thrive on such a diet he is more difficult than a human being.

It is curious that no one has given advice at a time when, beside food cards, that is the only plentiful commodity—on the subject of Maize. The early-ripening kinds such as I am growing at Wisley last year should be a useful crop now that gardeners are going in for live stock. Raised under glass and pricked out, only varieties of Maize should do well in sunny districts, and the amount of "straw" which the plant produces should make it additionally valuable. Even for its industrial uses it might be tried, as I believe it makes an excellent paper of the better sort.

A fruit grower who attended the recent conference gave me a most interesting account of Mr Protheroe's speech, and among the many points to which he referred I was particularly struck by his reference to the multiplicity of forms of agricultural baskets. I myself have been unable to fathom the mysteries which he

FIG. 1.—A FLOWER-SPIKE OF LILIUM SPECIOSUM MAG-NIFICUM GROWN IN THE WOODLAND BEDBROOK (see p. 110)

behind the strike and sieve and half sieve and pot. On the chance of these lines meeting the watchful eyes I would suggest that the Royal Horticultural Society might confer a boon on everybody by holding an exhibition of agricultural baskets in connection with one of its fortnightly shows, each exhibit to be clearly labelled with its name, county of origin, and use. Perhaps such an exhibition would bring home to those engaged in distribution the possibility of reducing the number and even improving the type. I am told that cane baskets are to be put on the market this year, and it will be of interest to learn whether their "life" is less limited than that of the basket made of withies.

At the end of February I went through the north east wind to Wisley to see whether spring was at hand, and among the many signs of life's awakening which I saw was a plant of Daphne Mezereum, pure snow white with no trace of cream, nor sign of pushing leaf. It stood peer

among a group of [illegible] creamy-white and magenta flowers [illegible] them look dowdy; that, a plant of Iberis Wintergreen flowering in its pale blue [illegible] a cleft rock, and a batch of brilliant-stained Primula obconica, well repaid me for my visit. I returned to my Cabbages and Kale and my [illegible] goose steps with, as it were, the reassurance that we have only to be resolute in the practice of this present utility gardening for the sun of beauty to rise [illegible] bows to be sown again with green [illegible] borders to be bright again. [illegible] by the memory of those ancient [illegible] management." Only be strong [illegible] quit you like men," and [illegible] plant rampant Asters to make [illegible] Sunflower.—*A. N.*

USE FOR PEAT.

THE antiseptic power of [illegible] known. Last autumn, besides [illegible] broken peat (black, brick peat [illegible] fresh Heather and Fern peat [illegible] surface, sprinkling of peat was [illegible] under cloches; whether from this cause or some other the plants did not damp off. In replanting it was interesting to observe how the roots had seized upon and invaded bits of the peat, and the same fact was observed in the case of Erigeron.

The grave inconveniences of fermenting urine in open vessels for manurial purposes, as do the Chinese, led me to try to reinforce some peat. Two 12 inch pots were filled therewith, and alternately used as a garden urinal as they became saturated. They were started in July, and not used during the winter nor until May, when they were again casually used. A certain amount of stove and rain had caused the effluent to overflow the underlying saucers, so that some ammoniacal odour developed. On being allowed to dry out again under shelter one was again put to use for several months without smell or congregation of flies. In May a sample was taken and compared with the original (raw Heather peat):—

PERCENTAGES IN AIR DRIED MATERIAL.

	Original peat.	After 18 months.	Effluent ditto per 100 c.c.
Water loss at 110° C.	14·89	22·61	
Potash as K_2O	0·2	6·48	0·098
Phosphoric acid (P_2O_5)	0·084	1·4	0·062
Silica	8·42	54·7	—

It will be seen that the potash had been well retained, but was evidently being leached out, as also was occurring with the phosphoric acid, the quantity of effluent lost was not known.

On keeping, the effluent remains a dark coffee coloured fluid perfectly odour free, and in diluted state has been given to various plants, including Leeks, as also the now pulverised material as a top dressing. A later arrangement used all through last summer was to have two 12 inch pots superposed after filling them with the peat; still in use they stand odourless. The nitrogen content would be interesting, but one cannot do everything in these days. Food production is much dependent on manurial supply, and I venture to call attention to this apparently unobjectionable mode of utilising some otherwise waste material, so many millions of tons of which annually are devoted to the ocean. I notice that Dumont strongly advises the addition of all room sweepings (fluff, etc.) to the compost heap.

In the day to come when the much harassed battlefield area is [illegible] put under cultivation the need for humus will be admittedly of prime importance. Humus could probably be most satisfactorily supplied by heavy dressings of peat. Is it too much to hope that the extensive peat areas of Germany should be made to contribute to undo what Germans has done. I commend the idea to the various Foreign Offices.—*H. E. Durham.*

NEW OR NOTEWORTHY PLANTS.

JUBAEOPSIS CAFFRA.

SEEDS of Jubaeopsis caffra, a new and very interesting Palm, have lately been received at Kew from Pondoland. It is, according to Dr. Beccari, a member of the Cocos family, and a near ally of the Chilian Jubaea, therefore as much a stranger in Africa as a Phoenix would be if found wild in America. The species was discovered in 1909 by Mr. C. Ross in East Pondoland, but had never been introduced into cultivation. The leaves are pinnate and its broad-based, trigonous nuts are 1¼ inch in diameter, with the three vents or pores at the sides instead of the base. They differ from the nuts of Jubaea in being narrowed to a point at one end, Jubaea being pointed at both ends. Jubaea spectabilis, the Coquito Palm, is represented by a magnificent tree in the Temperate House, where it has grown happily for probably fifty years. In Chili the stems of this Palm are tapped for their delicious honey-like juice. There are probably many gallons of juice in the Kew tree. *W. W.*

TREES AND SHRUBS.

RHODODENDRON PRAECOX.

THE value of this Rhododendron for greenhouse decoration is referred to by Mr. Watson in "Notes from Kew," on p. 97. An interesting feature connected with its early history is that when shown at a meeting of the Royal Horticultural Society on March 12, 1861, it was only given a second class certificate, which is now an obsolete award. Strange as it may appear when viewed in the light of present-day events, a first class certificate was at the same meeting awarded to a variegated leaved form of Agathaea caelestis, a worthless thing. Still, it must be remembered that at that time variegated leaved plants were very popular. In proof of this it may be mentioned that at the International Horticultural Exhibition, 1866, a prize of £5 was offered for 50 hardy variegated alpine and herbaceous plants.

R. praecox was raised by the late Mr. Isaac Davies, of Ormskirk, to whom we are indebted for many other beautiful varieties of Rhododendron. The parents were the Himalayan R. ciliatum and the purple-flowered R. dahuricum. From R. ciliatum and R. virgatum was raised R. multiflorum, remarkable for its great profusion of pale blush flowers. Pixie Queen and Queen of Dwarfs are two others much in the same way, but dwarfer, and with pure white flowers.

A very desirable race of greenhouse varieties was obtained by the intercrossing of R. multiflorum and R. Edgeworthii, the latter being remarkable for its large, fragrant blossoms. R. Edgeworthii is of somewhat straggling habit, but in the progeny this is counterbalanced by the dwarf habit of R. multiflorum. The varieties of this group were Countess of Derby, Lady Skelmersdale, Countess of Sefton, and Mrs. James Shawe, all with large, deliciously scented blossoms, which are white or slightly tinted. Another interesting hybrid, R. Daviesii, was raised from R. retusum and R. javanicum. R. Daviesii was very pretty, but of somewhat ungainly growth. This is but a tithe of the varieties raised by Mr. Davies. *W. T.*

PRUNUS PISSARTII.

NEVER before do I remember Prunus Pissartii so beautiful as it is this season. The trees are a mass of bloom, and very effective, with the white petals set in a background of purplish tints. In previous seasons this tree has been one of the first to suffer from the depredations of the bullfinch, and these birds have always done their destructive work so well in destroying the flower-buds that I have never seen more than a dozen or so blooms on our trees before. *G. H. H. W.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

ASPARAGUS.—For the formation of new Asparagus beds the first week in April is quite soon enough to plant, where the soil is light, but on heavier soil planting may well be deferred to the end of that month. One or two-year-old plants may be transplanted with little injury to the roots, especially if they are home-grown. Where the nature of the ground and the position are favourable to growing Asparagus on the level, this proves a good method. On unfavourable ground, such as heavy clay, the ground should be trenched and enriched with plenty of manure, road scrapings, garden refuse and wood ashes, leaving the surface as rough as possible until the time for planting. On heavy soils it is desirable to plant on raised beds, about 1 foot above the ground level. The beds should be 4 feet in width, thus allowing room for three rows of plants; provide 2 feet alleys between the beds.

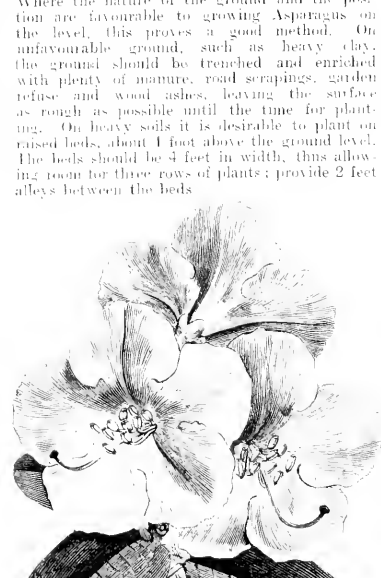

FIG. 52. RHODODENDRON PRAECOX.

POTATOS.—A few early varieties of Potatos may be planted in a sheltered position, such as the foot of a south wall in front of glass-houses. A large amount of soil is not necessary, but it should be light and rich.

SEED-SOWING.—Owing to the dull weather and moist atmosphere, heavy, clayey land is not yet sufficiently pulverised to be easily workable. To sow seeds of choice vegetables in cold, wet, and badly prepared ground is so much labour and expense wasted. It is better to delay seed sowing a fortnight or so; even a few days make a great difference in the state of the ground, especially in March. The seed should, however, be sown directly the soil is in a fit state to receive it. The following vegetables may all be sown outside on a south border or other warm position: Carrots Champion, Scarlet Horn, and Early Gem; Turnips Early Milan and Snowball; Cauliflowers Magnum Bonum, Forerunner, and Early Mammoth; Brussels Sprouts Dwarf Gem, Matchless, and Exhibition; Lettuces Cabbage and Cos; and Cabbages Earliest and Emperor. Marjoram and Basil should be sown in gentle heat for planting out afterwards. Gradus and Early Giant Peas may be sown to succeed those recommended in the Calendar of February 16.

EARLY BEET.—A small sowing of Beet may be made on a gentle hotbed or warm border, thinning the seedlings to 6 inches apart. Globe varieties are best for early supplies. Give air on all favourable occasions, and protect early sowings made in the open from frost and birds.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

THE CHERRY HOUSE.—One of the houses in these gardens devoted entirely to established Cherry trees presents a very beautiful sight, for the trees are in full flower. Standard, half-standard, dwarf fan-trained, and cordon trees appear to vie with each other in flowering. At this stage of development the valves of the hot-water pipes should be opened a little to maintain a dry, buoyant atmosphere, and the amount of ventilation increased to favour the setting of the fruits. This may also be assisted by pollinating the blossoms daily by the use of a rabbit's tail. Directly the fruit is set, should there be the least trace of aphis, fumigate the house. Keep a sharp watch for grubs that attack the foliage; they can generally be detected by observing the neatly folded leaves in which they hide. Hand picking must be resorted to, for if allowed to go unchecked the grub will destroy all the foliage and eat into every fruit. Fumigations or insecticides are useless against this pest. A night temperature of 45° with a rise of 10° by day will be warm enough for trees in flower.

THE ORCHARD HOUSE.—The mild weather had its effect on trees in late houses. It has caused the flower-buds of Apricots, Cherries, Peaches, Nectarines, and some of the earliest Pears, to burst, necessitating a little warmth in the hot-water pipes. In a house of this description shelves near the glass can be reserved for successional batches of Strawberries where they will receive the maximum amount of sunlight and air. Even at this period water must be given with great care until growth is more active, for it is as injurious for pot fruits, and even established trees in borders, to be over-watered at this stage as to suffer from drought. Watering should be done only in the forenoon; for several weeks yet, once a day will be sufficient. A constant circulation of air must be maintained, especially as the trees come into flower. Admit a little air at night through the top ventilators, except in frosty weather. Aphis must be kept in check by fumigating, followed by vigorous syringings of tepid water. The syringings must cease when the trees are in flower, as it is useless to attempt to pollinate flowers in a damp atmosphere.

FRUIT TREES IN POTS.—The earliest trees will now require water more often, with, occasionally, light stimulants. Concentrated fertilisers may either be used as weak solutions or scattered on the surface and watered in. Weak soot water, given every week or ten days, will improve the fruit and foliage. Syringe the trees with tepid water twice daily; in the morning when the temperature increases, and once again early in the afternoon, when the house is closed. The last syringing should be done in time for the foliage to get dry, or nearly so, before night. On bright, sunny days a higher temperature will do no harm, but top and bottom ventilation must be increased, and the fires kept to the lowest limits, as the sun gains power. A night temperature of 55°, or even a few degrees lower, will be ample warmth.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to SIR JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

RE-POTTING.—Many different species and hybrids are responding to the influence of the spring sunlight, and the development of new roots and top growth show that the resting season is over. No time should be lost in re-potting Angulua Cliftonii, A. Ruckeri, A. uniflora, and A. eburnea. After their long season of rest these Orchids are becoming active at the roots. They are strongly-rooted plants, and require a compost formed of equal parts fibrous loam, passed through a ½ inch sieve in order to remove all the small particles, and Osmunda or A 1 fibre, adding a little Sphagnum moss and crushed

crocks. Place sufficient crocks in the bottom of the pot to ensure effective drainage. Anguloas should be grown in a light position in the intermediate house, or in the lightest and warmest part of the Odontoglossum house. Coelogyne Massangeana, C. Dayana, C. Lowii, C. barbata, and C. Mooreana are making new growths, and the plants may be repotted. Orchid pans suspended from the roof rafters form the most suitable receptacles, with a rooting medium similar to that advised for Anguloas. The plants should be grown in the warmest position in the Cattleya house. C. pandurata is also making new growth, and plants that have overgrown their receptacles may be repotted. If any of these plants have sufficient rooting space for another season, but the soil has become sour or exhausted, it may be picked from between the roots by the aid of a pointed stick, all small particles washed from among the drainage, and new materials substituted. The new compost should consist of a mixture of equal parts good fibrous loam, A I fibre, and Sphagnum moss, the whole chopped rather small, and well mixed with crushed crocks. The plants should be grown in pans and suspended from the roof rafters in the warmest house. In the process of potting cut away the old back pseudo bulbs, leaving only two or three behind each healthy growth. Plenty of room is necessary in the pans, as the rhizomes will extend some inches each year. After being potted water should be applied sparingly until the plants have rooted freely in the new compost, after which they should receive liberal supplies until the new pseudo bulbs are completed. Plants of Bulbophyllum grandiflorum, B. Eriessonii, B. Reinwardtii, B. virescens, and others that have commenced root action should be afforded fresh rooting materials while there, including B. anceps, B. barbigerum, B. Lobbii, and B. saltatorium which are developing their flower scapes will be better to pot later on in the year. Those having a creeping habit are best grown in Teak wood baskets. Plants of this type that have overgrown their receptacles may, if the compost is still in good condition, have their roots and pseudo bulbs trained round and pegged down to the compost thus making the plants more shapely. Plants of more compact habit are best grown in shallow Orchid pans. Cirrhopetalum pulchrum, C. elegans, C. elegantissimum, C. Collettii, and C. ornatissimum are also showing root action, and should be dealt with in a similar manner. Many species of the genus Megaclinium are sending up their flower spikes, and their repotting should be deferred for the present. Catasetum macrocarpum, C. Cliftonii, and C. tabulare should be repotted, using a similar compost to that advised for Coelogyne pandurata.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

STRAWBERRIES.—Take the earliest opportunity to lightly fork the soil of Strawberry plantations; and, if needed, apply a light dressing of well-decayed manure. I shall not apply manure to our plants just now, but intend to give them a very light dressing of Peruvian guano when the flower trusses appear. I do not favour the making of new plantations in the spring, but in cold and late districts spring planting may be a distinct success. A very successful cultivator of the British Queen variety recently informed me that the best system with growing this variety was to plant in rows at 6 inches from plant to plant, and at the ordinary distance between the rows. I hope to try this method as an experiment. Perhaps some others of the many readers of the *Gardeners' Chronicle* may have tried this method, and their experience would be valuable. I do not advise the planting out of the earliest forced Strawberries from pots. Rather wait a month, when the weather will be more genial.

ALPINE STRAWBERRIES. In my remarks on p. 55 I drew attention to the value of Alpine Strawberries, and recommended that the plants be raised from seed. I have to-day made an examination of the plants in these gardens that were set out in October last, and I could not detect a failure. The soil will be first trodden firmly and then kept hoed as required. By planting runners in the early spring it is possible, however, to gain a little time over plants raised from seed sown at the same period. The runners may now be planted, three in a group, allowing a space of about 18 inches from group to group, and the same distance between the rows. If the runners receive careful attention for the next few months, and all flower trusses and off sets are removed until the first week in July, a fair crop may be expected in the autumn, mainly during the latter half of August and through September. These spring-planted runners will not, however, be so good as the seedlings planted out last autumn. Well-decayed leaf mould is one of the best manures for Alpine Strawberries, and is preferable to farmyard or stable manure. Next to the leaf mould I would advise the use of manure from a spent Mushroom-bed. Plantations that were made last autumn may soon receive a light dressing of lime, repeating the application at a later date to keep slugs in check, and otherwise assist growth.

THE BLOSSOMING PERIOD.—The cold weather has retarded the flowering of fruit trees, which is an advantage, for the buds were developing too fast. The fruit-buds of Apricots are being retarded, and so are those of both Peaches and Nectarines. Plums in the open and Damsons are showing well for fruiting. With Pears and Apples the show is but partial; some kinds look promising: of Pears, Clapp's Favourite is very good, and so is Bismarck amongst Apples. Our trees of this Apple have not failed to furnish a crop for twenty years past; it is the earliest variety at Gunnersbury to flower, but the tree never fails to set a good crop. So far I have not, in consequence of the cold weather, fixed up the netting on the fruit walls. This should not be done before the flowers are just on the point of expanding.

PLANTS UNDER GLASS.

By E. BECKETT, Gardener to LADY WANTAGE, Lockinge Park, Berkshire.

EUPHORBIA PULCHERRIMA (POINSETTIA).—A start should be made with the propagation of this plant before the weather gets too warm; the bulk of the stock should be rooted before the end of April, as, after that time, the cuttings do not root readily. The old plants may be placed in a warmth and moisture to make suitable growth for cuttings. When the shoots are 2 or 3 inches long strip the plants into a cooler house for a few days before taking off the cuttings. The shoots will root better after this treatment, as the cuttings will not be so liable to flag. Take the shoots off with a heel and insert them in small pots filled with fine sand. Plunge the pots in a hot bed in a propagating case and shade them from sunshine until they have rooted.

BEGONIA GLOIRE DE SCEAUX.—Extreme care is needed to cultivate Begonia Gloire de Sceaux to perfection. A check to growth, especially during the later stages, will be almost sure to cause an attack of the leaf disease, to which this plant is subject. When the plants have finished flowering they should be slightly cut back and placed in a house having a warm, moist atmosphere, to produce shoots for cuttings. When the shoots are large enough, insert them singly in thumb pots filled with light, sandy soil, and plunge the pots in a hot bed in a propagating case. From the time the cuttings are rooted they should grow steadily in a genial atmosphere, syringe them with tepid rain water twice daily and shade them in bright, sunny weather. A compost consisting of fibrous loam, peat, decayed leaf mould, old lime rubble, and sharp sand in suitable proportions forms a suitable rooting medium. Much care is necessary in affording water at the roots, especially when the plants have been recently repotted. When they commence to open their flowers, a cooler and drier atmosphere will be necessary.

SCHIZANTHUS AND CLARKIA.—Some of the earliest of these useful annuals are coming into flower, and, as the pots are full of roots, plenty of stimulants should be used. Attend to the staking of later plants; Clarkias especially must be carefully attended to in this matter. Grow the plants in cool conditions, using fire-heat only in times of severe frost. Lightly fumigate the house containing annuals in pots at regular intervals to destroy aphis. Another sowing of Mignonette may be made in 3-inch pots.

STATICE SUWOROWII.—This is an easily grown plant, and is useful for furnishing the greenhouse or conservatory during the summer months. It may be raised from seeds sown now in boxes or pans in a light, sandy compost. When the seedlings are large enough to handle, pot them singly into 3-inch pots and keep them growing slowly near the glass in a cool house. Shift them when ready into 5-inch or 6-inch pots, using a compost of loam, leaf soil, manure from an old Mushroom-bed, and sharp sand.

POT ROSES. Roses which have finished flowering should be placed out-of-doors to make room for later batches. For the present they can be placed closely together in a sheltered position. They must receive regular attention in regard to watering, and stimulants must be given about once a week. Syringe the foliage occasionally with a mixture of soft soap and sulphur to keep it free from mildew and aphis. When all danger of severe frost is over, the pots should be plunged in ashes in an open situation.

CLIMBING ROSES.—When the trees have finished flowering, the old flowering wood must be cut hard back to encourage the growth of young shoots, which will be required for next season's flowering. Only sufficient of these shoots to cover the trellis should be retained, trained about one foot apart. Plenty of water must be afforded while the trees are in active growth, and this should be supplemented occasionally with diluted liquid manure. It is necessary that the foliage be kept free from mildew and insect pests, and during warm weather the trees should be sprayed with rain water each afternoon.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

HONEYSUCKLES. Varieties of Lonicera Periclymenum will now require pruning. Those growing on arches should be cut hard back with a pair of shears; if necessary, save some of the longer shoots to replace outworn ones. The late-flowering Dutch Honeysuckle, if filling the space allotted to it, should have all the growths pruned hard back, which induces the production of a limited number of vigorous growths instead of quantities of weakly ones. When in good condition, these yield enormous racemes of flowers, which require attention to keep them fastened securely to the supports. The Trumpet Honeysuckle may also be pruned now. Should Lonicera Standishii have finished flowering, this, too, may be closely cut, but it does well in bush form without very much pruning.

ROSES.—Winter mulchings should be removed forthwith from Roses, and pruning commenced, to be followed by lightly forking the surface soil. Where other plants are grown with Roses a charming effect is produced by masses of Fellenberg and Hermosa, carpeted with Nepeta Mussini planted very close. Every alternate plant should be cut in June, so as to continue the effect when those uncut have finished flowering.

TUBEROUS BEGONIAS.—The tubers should be removed from their winter quarters, and placed in heaps in a late vinery or other suitable place, where they can be kept moist without being often watered. Mats or canvas sheets spread over them help to keep them moist, and induce simultaneous growth in all the tubers. Usually it is the best plan to box up the tubers after roots appear with the shoots. A suitable compost is one of half loam and half rough leaf-mould. Do not quite cover the tubers with soil for a week or two, but after this they should be completely covered. One good soaking of water will suffice the plants for several days, especially if shading is used. They should not be kept too long in a glass structure; as soon as it is safe to transfer them to a cold frame, this should be done. There is no need to try to hurry growth, as it progresses very rapidly during the latter weeks of May. Large tubers with several shoots should be divided before planting them in boxes. Labour may be saved by planting tubers in April similarly to Potatos, but the plants will flower rather late in the season.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41, Wellington Street, Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR MARCH.

THURSDAY, MARCH 21—
Manchester and N. of England Orchid. Soc. meet

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 41.9.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, March 14: 10 a.m.: Bar. 30.1; temp. 49.5°. Weather—Fine.

The Manufacture of Nitrogen Compounds by Plants.

It is curious how little is known with certainty of the chemical processes—among the most important which occur in Nature—which enable the living plant to build up organic nitrogen compounds from the nitrogen contained in the inorganic nitrates which the plant absorbs from the soil. The question has, of course, been the subject of endless speculation, and of much experimentation, but no one has yet been able to trace to the general satisfaction of men of science the sequence of chemical processes whereby nitrogen brought into the plant in the relatively simple form of nitrates is promoted to become an integral part of the complex organic nitrogen compounds—the proteins—on which the life of the living organism depends. The most recent observations* throw some light on this obscure subject. Professor Moore, who is responsible for these observations, claims that dilute solutions of nitrates exposed to sunlight undergo conversion into nitrites. This chemical change—from nitrate to nitrite—involves an uptake of energy, and the source of the energy employed in the operation is sunlight. Further, according to Professor Moore, if green leaves are immersed in the solution of nitrates exposed to sunlight, nitrites do not accumulate in the solution, and from this fact he concludes that the nitrates are absorbed by the leaves. Professor Moore infers from these observations that in the normal life of the plant the nitrates absorbed by the root pass into the leaves and are there, by the agency of sunlight, converted into nitrites. He concludes that the first stage of synthesis of organic nitrogen compounds is carried out by the green leaf aided by sunlight.

Incidentally, the author states that no ozone occurs in the air at surface level, and that the odour of fresh air is probably caused by nitrogen trioxide, which, he believes, is formed by the action of sunlight, rich in ultra-violet rays, on air and aqueous vapour in the upper regions of the atmosphere. He suggests that rain brings down the combined nitrogen in the form of nitrates, and thus makes a contribution to the fertility of the soil. This hypothesis has often been put forward, and two or three decades ago it was commonly held that an important source from which soil nitrogen compounds are obtained is the nitrogen of the air. The discovery of nitrogen fixation by the nodule organisms of leguminous plants, and by certain soil bacteria, helped to divert attention from this possible source of supply of combined nitrogen, and it is therefore interesting to note that on the basis of Professor Moore's recent observations these old ideas appear to be in course of rehabilitation.

* "The Formation of Nitrites from Nitrates in Aqueous Solution by the Action of Sunlight and the Assimilation of the Nitrates by Green Leaves in Sunlight." By Prof. B. Moore. A paper read before the Royal Society, Dec. 13, 1917.

ROYAL VISIT TO READING.—In the course of the visit of the KING and QUEEN to Reading on Tuesday last, they inspected the establishment of Messrs. SUTTON AND SONS, and were exceedingly interested in the various processes connected with this vast seed business. Their Majesties were particularly impressed by the preparations being made for executing a large order for flower seeds from the Director of Registration of the graves of soldiers in France for beautifying the military cemeteries, a work in which the Prince of WALES takes the keenest interest. Both the KING and QUEEN expressed themselves delighted with everything they saw, and especially with the efficient work being done to increase the amount of food grown in this country.

THE GROWTH OF TREES.—Measurements made by Mr. A. MALLOCK, F.R.S. and reported at a recent meeting of the Royal Society, show that trees exhibit a well marked daily periodicity of variation in girth, with a maximum at night and a minimum soon after noon.

CUNAO OR CHINESE GAMBIER. The dye known as Chinese Gambier is the product of crushing and soaking the root of a plant known by the Chinese as "Cunao," and drawing off and concentrating the liquor therefrom. According to a report by the United States Consul-General in Hong Kong, remarks the *Journal of the Society of Arts*, there are two qualities of the product reaching the Hong-Kong market from Canton and other ports, one of which is the product of Kwangsi and Yunnan Provinces, coming largely from Lungchow and Luk Po in Kwangsi, and from Mengtse and Yunnan fu in Yunnan Province. The other quality is the product of Indo-China and certain other parts of Yunnan Province. Usually the Indo-Chinese product is employed for the first dyeing of a cloth or for the coarser work in other materials, while the Chinese product is used for the second or finishing dye, because of the deep, rich brown gloss it gives cloth.

ARSENIC AS A STIMULANT OF NITROGEN FIXING BACTERIA.—Experiments carried out by J. E. GREAVES, of the Utah Agricultural Experiment Station,* show that arsenic, particularly in the form of lead arsenate, has a marked effect in stimulating ammonifying and nitrifying soil bacteria.

* *Journ. of Agric. Research*, VI., 2; see also *Agric. News*, Jan. 26, 1918.

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS.—The annual report of the Royal Society for the Protection of Birds constitutes a most interesting record of useful work. The report comments unfavourably on the ill-advised action taken by public bodies during the year in encouraging and even remunerating the wholesale slaughter of birds, many of them of the utmost value to the farmer and gardener, and especially condemns the formation of so-called "sparrow" clubs. The fact is also mentioned that owing to the scarcity of insectivorous birds consequent on their destruction, there was last summer a plague of caterpillars and other pests in many parts of the country, which destroyed great quantities of valuable food.

GLASS JARS FOR PRESERVING.—All who have not already obtained a sufficient stock of glass jars for preserving fruit and vegetables during the coming season are advised to place their orders with local retailers without delay. If the orders are deferred the jars may be difficult to obtain, and the prices which will have to be paid may be higher than they are at present. Glass jars with screw tops and rubber rings can be obtained from most makers at the following maximum prices:—5s. 9d. per dozen for 2-lb. jars in not fewer than 20 gross lots when purchased co-operatively by societies, and when the purchasing society accepts delivery at the railway station and undertakes distribution; 6s. 3d. per dozen for 2-lb. jars in not fewer than 20 gross lots when distribution is undertaken by the retailer to the members of the society or organisation placing the order. For small quantities the maximum prices per dozen are:—6s. 6d. per dozen for 1-lb. jars; 7s. 6d. per dozen for 2-lb. jars; 10s. per dozen for 3-lb. jars; 11s. 6d. per dozen for 4-lb. jars. These prices may not apply to orders placed after March 31, inasmuch as after that date makers may find themselves obliged to increase the prices. There remains another two weeks therefore in which purchasers may be certain of obtaining glass jars at the above rates. Another advantage in placing orders at once is that delivery in time for use in the early part of the season should be secured.

CO-OPERATIVE BASKET MAKING.—The Food Production Department has established a co-operative basket-making society to supplement the short supplies of agricultural baskets for market work.

BRITISH FLAX.—The President of the Board of Trade has appointed a Committee to investigate the question of increasing the supply of flax in the British Empire. The Chairman of the Committee is Lord COLWYN (formerly Sir FREDERICK HENRY SMITH, Bt.), and the Vice-Chairman Sir FRANK WARNER, K.B.E. (President of the Silk Association). The address of the Committee is Gwydyr House, Whitehall, S.W. 1.

CONTROLLED PRICES OF ONIONS.—The Ministry of Food has fixed the following prices for home-grown Onions (f.o.r. or f.o.b. to growers):—Early autumn (up to Nov. 1), £15 t.o.r., f.o.b.; late autumn (Nov. 1 to Jan. 1), £16 10s. f.o.r., f.o.b.; winter and spring (after Jan. 1), £18 f.o.r., f.o.b., provided that growers can make the necessary arrangements in time.

SUPERFLUOUS WOOD IN FRUIT TREES.—Mr. C. MARTIN, County Horticultural Instructor in the Isle of Wight, advocates* the systematic compression of the wood of unfruitful trees making too much growth in order to force them into a fertile condition. He has devised a simple form of band bolted either on one or both sides by a screw, which can be tightened at will. Mr. MARTIN recommends that the smooth band should be put in place when the

* *Superfluous Wood in Fruit and other Trees.*

sap is down, and holds that this method will do away with the labour of root-pruning. The "throttle" has the advantage that by a turn of the screws the pressure can be increased or released.

GOVERNMENT CONTROL OF POTATOES.—Important announcements were made by Major E. A. BELCHER, Director of Vegetable Supplies, Ministry of Food, at the annual meeting of the National Federation of Fruit and Potato Trades Associations on the 12th inst. The outstanding points of his address were: There are only sufficient stocks of Potatoes to see us through the present season; Compulsory use of Potatoes in bread is to be left to local option; Loss consequent upon restriction of market areas is to be made up to growers of 1917 crop. Minimum price for 1918 crop is to be £5 15s. a ton. Factories are being established to manufacture by-products from any surplus, or any Potatoes unfit for human food of the 1917 or later crops.

PRISONERS OF WAR IN AGRICULTURE.—Nearly 9,000 prisoners of war are employed on the land in England and Wales.

LAND WOMEN'S WAGES.—The minimum wage for women enrolled in the Land Army has been increased from 16s. to 20s. per week, and for those who have passed their efficiency test 22s. is now the minimum. Efficiency tests are being held weekly in Monmouth, and will be so held until all the women land workers have been officially tested. Owing to the increased number of recruits new training centres for women have been opened in Cambridgeshire and Hertfordshire.

THE HUNGARIAN FRUIT TRADE. We learn from the *Board of Trade Journal* that the Hungarian Government has established a Central Vegetable and Fruit Company to control trade in vegetables and fruit. The whole country complains of the shortage of those commodities and of the bad condition in which they arrive at the market. The Central Company recently proposed to overcome this evil by taking control of the whole trade. This plan has been opposed by dealers and producers to combine and form the National Company of Hungarian Vegetable and Fruit Producers and Dealers (Limited) ("Frugal"), with a share capital of 1,000,000 kronen, subscribed by 341 producers and dealers as well as by the Agricultural and Commercial Society, the "Agricola," which itself represents 50,000 producers. The new company will, in agreement with the Hungarian National Food Office, negotiate the export of surplus Hungarian fruit and vegetables, especially to Austria.

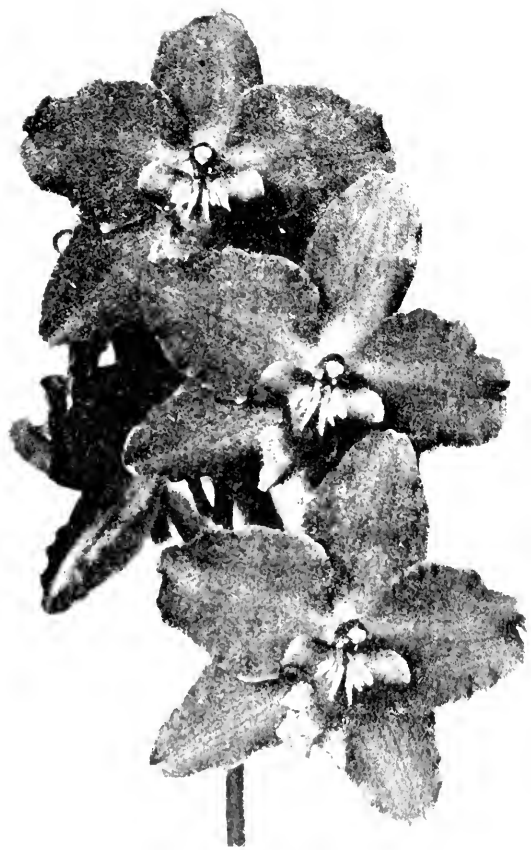
NETTLE-FIBRE.—According to the *Journal of the Royal Society of Arts*, the prospects of the Nettle-fibre industry are none too bright. First it is necessary to obtain the Nettles and plant them out singly, and both the cutting and harvesting require labour at the same time as the more valuable crops. When harvested there is a yield from wild Nettles of 4 cwt. to 6 and from cultivated Nettles of up to 50 per cent. of bast fibre. The fibre is prepared, according to a Vienna method, by first stripping and then roasting the stems, when a fibre suitable for cordage and pile spinning is recovered. Upon a Danish system the Nettles are cut and stacked for the winter, then tops and leaves are removed and retting is done either in a pond or in four days' immersion in hot water. The stalks are dried, broken, scutched and hackled by a system of cordage and carding fibre has been obtained. All textile fibres in course of use are subject from the battlefield and have been under examination in British laboratories. Nettle-fibre sandbags and cap and coat linings have been identified.

PUBLICATIONS RECEIVED.—*The Garden from January to December.* By R. S. BROWN. (London: Morton & Burt, Ltd.) Price 6d.

FRUIT TREE SPRAYING.

GROWERS of fruit trees who have not yet done their winter spraying should [illegible] matter at once, before the buds [illegible] become active. Fruit trees, as a rule, in parts of the country, remain dormant [illegible] the end of March. Apple, Pear, Plum, Cherry trees and bushes need not [illegible] by being winter sprayed, although it is clearly understood that damage may be done spraying with winter washes if the work is delayed until the buds begin to burst. Trees [illegible] are covered with moss and lichen should be [illegible] Strain through sacking, but [illegible] covering [illegible] Cover the [illegible] side of [illegible] that a thin coating [illegible] It is best to make the [illegible] ds are just beginning [illegible] ney to the outer leaves [illegible] s are permanent damage [illegible] t that this wash is to [illegible] ng the insects from hatching [illegible] also the numbers of [illegible] e earlier.

Knapsack Sprayers. Many [illegible] applying these washes, but care [illegible] all the valves and internal



[illegible] (See page 118.)

sprayed with a caustic soda wash. Dissolve [illegible] caustic soda [illegible] of water, then add [illegible] of caustic soda paste. To [illegible] per cent. of a small quantity of water and add the caustic soda solution made up to 10 gallons. Stir all the time through dissolved and the paste has dissolved [illegible] the caustic action.

Boiling water should be [illegible] and to every gallon of water [illegible] caustic soda [illegible] per cent. solution is desired. For this purpose [illegible] lime must be employed. The lime must [illegible] and slaked. For treating 10 trees [illegible] 10 to 15 lbs. of lime by adding just as much water as the lime will take up. When the lime is broken down to a fine powder add water up to 10 gallons of the mixture thoroughly after use. To [illegible] Knapsack. Machine from the clogging effects of lime-wash, a coarse garden syringe may be used, though it is more difficult to apply the wash evenly and thoroughly by this means.

The large number of eggs which are to be found on fruit trees at the present time indicate that there are [illegible] a bad attack of caterpillars similar to that which took place last year. The trees, therefore, should be carefully examined with a pocket-lens, each [illegible] and if eggs are found [illegible] needles and the attack [illegible] develop. Every care should be taken to preserve the fruit crop from [illegible] spraying is one of the best means of preventing loss from disease and insect pests.

ON INCREASED FOOD PRODUCTION.

WINTER GREENS ON NEWLY TURNED-UP PASTURE LAND.

LARGE quantities of Brassicas were grown at Aldenham during the past season on newly broken up rough pasture, with splendid results in every case. The illustration in fig. 54 shows breadths of Sprouting Broccoli and Scotch Kale; Autumn Giant Cauliflowers with Colewort Cabbages were grown between the Broccoli and Kales, the Cabbages and Cauliflowers being now cleared. *Edwin Beckett, Aldenham House Garden, Elstree, Herts.*

ONIONS.

OWING to the reduction of imports it is necessary to increase the crop of home-grown Onions, and it is important that the greatest economy should be practised in the use of seed. Experienced growers who cultivate Onions by transplanting are aware that this method has many advantages over sowing. It economises seed (1½ lbs. of seed will suffice to raise the plants for planting one acre, as against 5·7 lbs required for sowing one acre). Transplanted plants also produce a bigger crop, and are less liable to be attacked by the Onion fly. The extra labour required for transplanting is set off by the smaller amount of weeding which is required.

Seedlings raised in beds or boxes in houses or frames in a minimum temperature of 40° and maximum of 55° require to be transplanted into boxes or frames before planting them in the open. Sowings in houses or frames may be made until the middle of March; in the case of later sowings it is not necessary to shift the plants into boxes or frames.

Air should be given whenever weather conditions are suitable. The seedlings should be well hardened off towards the end of March preparatory to planting in April.

Plant at 4 inches apart in rows, which should be made 1 foot apart (or more if horse cultivation is to be practised), and in planting take care that the plants are not put too deeply in the soil, which should be pressed firmly about the roots.

CELERY ALDENHAM PINK.

GROWERS of early Celery, whether for market or home use, should give this variety a trial. From a sowing made at the end of February, good heads will be ready for use early in October. My method of cultivation is as follows:—The seed is sown very thinly in shallow boxes, and germinated in a temperature of about 45°. A hot-bed is prepared, chiefly of leaves, and 4 inches of good sandy soil placed on the top. From the seed boxes the seedlings are pricked out 4 inches apart on the hot-bed. The frame is kept closed and well protected at night. As the days lengthen and the sun has more power, a little ventilation is given, but the frames are closed early in the afternoon and covered just before dusk. From this stage the plants are freely ventilated; a little later the lights are drawn back in the day and replaced at night. Celery must not be allowed to suffer from lack of moisture at the roots. Dustings of soot should be applied when the foliage is damp, to ward off attacks of Celery fly. Many growers imagine that Celery must be grown in trenches, but much of the Celery exhibited at shows is grown on the surface, and with half the labour expended on Celery grown in trenches. Trenches are opened 4 feet apart, 18 inches deep, and 12 inches wide. These are filled with half decayed horse manure, which is trodden down, and the soil again levelled. Early in May the plants are taken up with a good ball of soil, planted 1 foot apart in the trenches filled with manure, made firm at the roots and watered. Water must be given the roots freely, also weak liquid manure. Blanching is done by means of brown paper bands 6 inches wide; the first band placed around the base when the plants are about 8 to 10 inches high, and tied with three broad bands of Raffia. Further bands are required as the plants develop, and it is advisable, when putting on extra bands, to remove the ones put on previously, to permit of examining the plants. *C. Davis, Holy Wells Park Gardens, Ipswich.*

FIG. 54. WINTER GREENS PLANTED IN OLD PASTURE LAND.

CARROTS AND EARLY POTATOS.

A LARGE batch of Carrots was lifted in these gardens on January 24. The roots were in excellent condition, thus disproving the idea held by some gardeners that it is detrimental to the well-being of Carrots to leave them for so long in the ground. This particular sowing was made in ground of a somewhat heavy texture. The crop of another smaller sowing is still in the ground on the outskirts of a vine border, where the soil is lighter and somewhat raised above the surrounding level. This lot will come in after the store Carrots are finished, and before the spring sown batch is ready. The seed was sown on July 31, and the roots vary in size from the thickness of a lead pencil to that of a man's thumb.

Some venturesome enthusiasts at Moulden, in this county, planted a few Potatos the first week in February. Another grower in the same village planted a bushel of seed Potatos at the end of the second week of that month. Admitting how wonderfully early the sandy soil of Moulden gets warm, it can scarcely be more than once in a hundred seasons that such planting can prove successful. Early February is too soon for setting Potatos out of doors, no matter what the soil and position, unless it be in a garden in the extreme south. Radishes were sown at the same time between the rows of Potatos here alluded to, as an extra crop, and the whole surface was covered with straw litter. *C. T., Ampthill Park Gardens, Bedfordshire.*

FEEDING PIGS FROM SMALL GARDENS.

OF the two adjuncts to the home supply of food, mentioned on p. 68, I would prefer pigs to poultry. The pig will eat any waste refuse, within reason, from the household and garden. In towns and populous neighbourhoods the keeping of pigs is forbidden on account of the smell arising from dirty and badly kept sties; but the piggery can, and should, be kept as clean as a fowl-house. A pig, or several, could be kept in a small wooden house, the bottom of which should be boarded to prevent the animals from grubbing up the floor; a small square run outside the house is all that is necessary. Fowls are always troublesome, unless they are allowed to run at large, or have a good-sized run. They require more dry and hard food than pigs, which means corn or seeds of some kind. One can always calculate upon feeding a pig to a given size, but fowls will not always lay unless their special requirements are attended to at different seasons. Pigs fatten best and most quickly when confined within the limits of their sty and small run. For these reasons one or two pigs would be more easy to accommodate in the neighbourhood of a gardener's house, that of the tenant of a country house, or an allotment holder's residence, in districts where pig-keeping is allowed, than it would be to keep poultry in sufficient numbers to be of appreciable benefit to the household.

From the garden the pigs could be fed with Potato chats, Turnips, Swedes, Kohl Rabi, Beets, Mangolds, and the parings of Potatos and Turnips during winter. All these vegetables should be boiled and given to the pigs warm. In addition to the above there would be a considerable variety of waste scraps from the household. All the above would be available during some part of summer, when a considerable amount of green food could be given in the raw state, including Cabbage, Turnip, and other leaves of the Brassica tribe; also Beet, Clover, Lucerne, Vetches, and fresh, green grass.

In districts where Oats and Barley are the staple products of the farm, meal seeds, Barley dust, and even Barley meal, are available. Barley dust is the waste product in the shelling of pot Barley, and where Pearl Barley is made the dust is much richer, because it includes a portion of the meal. The latter is used as human food, in the shape of Barley bread and Barley meal porridge, but it is also used for feeding or fattening pigs. If a well-bred pig gets fairly good food for five months, and is then given Barley meal almost exclusively, it will give 120 lb. of the finest pork, especially if whey, buttermilk, and sour milk are added to the food when available.

Where Wheat and Mangolds form the staple products, sharps or middlings (the rougher parts of the grain of Wheat) are available as a supplementary food to the products of the garden; also brewers' grains, Peas, Oats, and Maize.

Nothing gives finer pork than the waste products of milk in the making of butter and cheese. These and skim milk should be used most freely just after the pigs are weaned at the age of six to eight weeks. In the way of utensils a copper, or merely a large metal pot, would be necessary to boil the requisite food. The animals require frequent feeding, but no more food should be given at one time than they can consume completely. *J. F.*

BEANS AND PEAS.

In addition to re-cropping the spaces occupied by first and second early Potatos, something may be obtained from the space occupied by maincrop and late varieties. Nothing is gained by planting these closer than 2½ feet between the rows and 1 foot between the tubers, and if every sixth or eighth row is missed the spaces may be filled by Haricot or Runner Beans or Peas, leaving the Bean crop to be harvested for winter use. Last season we secured an appreciable extra crop by planting one Broad Bean every 2 or 3 feet in the rows of late Potatos.

We failed last season to grow Haricot and Butter Beans from seeds obtained at the grocers. The seed was germinated under glass, and the seedlings planted out in the third week in May. The plants did not come into flower until September; they were grown alongside ordinary Runner Beans, which yielded a good and abundant supply of pods until the plants were cut down by frost in October. *J. E.*

DEGENERATION OF POTATOS see p. 120

I HAVE it on indisputable authority that deterioration concerned various skilful growers in Devon prior to the "terrible year 1845," and that these men took what seemed to them the best means to combat the evil. Their method was chiefly selection and careful treatment of sets; frequent change of sets was, in those days, rarely, if ever, practised. When the crop showed signs of ripening these men singled out all the plants which were greener and more vigorous than their fellows, marking each with a stick. At digging time these selected plants were carefully scrutinised, and if the yield was satisfactory all the tubers, except the chats and very large ones, were saved. They were laid out to green before being stored for the winter. Only the largest of these seed Potatos were cut before being planted, for cutting was not considered desirable. As is now held in some parts of Scotland, it was believed to induce glassiness and soapiness, so that sets larger than the present regulation size were planted, but at greater distances. In this respect there was no fixed distance except between the rows; the amount of space allowed each set depended on its size—a sound, common-sense method. By this plan, although home grown sets were used, a variety retained its vigour and productiveness for a long time.

Considerably later, in 1880, in the report of the House of Commons Committee which dealt with the deterioration of the Potato, more particularly with regard to its resistance to the disease, then called Peronospora infestans, it is stated that all the witnesses concurred in the necessity for the production of new varieties, as all Potatos had deteriorated in their disease-resisting powers. The late Director of Kew (then Mr. Thistleton Dyer, Assistant Director), one of the witnesses before the Committee, wrote a little later: "I do not doubt the possibility (not necessarily practicability) of eventually getting disease-resisting kinds," and went on to say that he felt that too much stress was laid on the consequences of deterioration. The principal cause of the mischief was, as with so many other cultivated plants, that we grew in great masses species that in nature are scattered about in different habitations. "We grow the Potato in large areas. Nature does not; we put our eggs, at any rate large parcels of them, into one basket. Nature knows better." And that last sentence, I have no doubt, largely explains the great susceptibility of our Potatos to late blight disease. Sir William Thistleton-Dyer showed great prescience in questioning the practicability of raising disease-resisting varieties, for the continued and careful Irish experiments have, so far at any rate, shown that the "disease-resisters" are either poor croppers or of poor quality, so that unless we can grow our Potatos more nearly after Nature's plan—and that is not practicable except for those who grow relatively small quantities for home consumption—we must resort to timely spraying as a preventive of disease.

But so far as the deterioration of the Potato in regard to its vigour and cropping powers is concerned, this can be remedied if more care is exercised in the selection and sprouting of the sets. The stocks in the hands of the reputable traders are right. It is the character of the seed Potatos sold by many greengrocers and ironmongers that is wrong. Too often these are merely small Potatos riddled from the ware late in the winter and palmed off, relatively cheaply, on an unsuspecting and unavoidably ignorant public as suitable for planting. Fortunately, many of the local authorities, realising this, have sternly refused to grant seed Potato licences to these tradespeople unless they show that the sale of proper sets has been a recognised part of their business. This is a move in the right direction. A further step would be for the seedsman to educate the greatly increasing Potato-growing public to the undoubted fact that just as it is necessary to deal with reputable firms and to pay a fair price to be sure of reliable seeds—seeds that will grow, and that are true to name—so it is essential to make sure of reliable Potato sets. But one may scan the advertisement pages of the horticultural journal for such an announcement in vain. The golden opportunity is allowed to pass.

My experience with cheap seed Potatos may be of interest. In 1916 I obtained possession of land late in the spring when good sets were unobtainable, so perforce I bought a quantity, cheaply enough, so far as price goes, which, as I well anticipated, proved to be merely smalls riddled from ware. They were mouldy, and the sprouts had been rubbed off, but it was a case of planting these or none, and there was no time to attempt to sprout them. As was only to be expected, there were many blanks, and the crop was to quote your fruit crops reports, "under." The crop was clamped when dry, till towards the end of December, when the ware was sold, leaving the small tubers. At that time I had bought "once grown" Lincolnshire sets for the next year's planting, but in view of the shortage I decided to increase the area of Potatos. As I found that by then the price of reliable sets was almost prohibitive, I decided to use the best of the small tubers as sets, and to carefully watch results. Early in January sufficient sets were boxed and placed under glass to sprout, and by the end of March most of them had made good shoots, and all were greened. In due course they were planted, and from these home-grown sets I had almost three times the yield of the previous year, though decidedly below that from the Lincolnshire "once-grown" sets, which gave a bumper crop. This tends to show that our stocks are right, but that our cultivation is wrong when we take Potatos from the clamp and plant them without proper preparation in greening and sprouting. *C. Bartlett.*

LIME AS A SOIL DRESSING.

A DRESSING of lime will in many instances increase and add to the value of vegetable crops. It is not too late to apply a dressing of 1 to 5 cwt. of lime per acre, and any soil which is sour from an excess of manure, too much water, or other cause, will give a greater and better return for such treatment. Lime is in itself a plant food, and its presence in soils is doubly valuable on account of setting free other plant foods, and especially in liberating the potash in clay land. *J. E.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

UNDESIRABLE APPLES.—I am pleased to find that my suggestion to reduce the number of varieties of Apples meets with support. I was doubtful at first about eliminating King of the Pippins, but knowing how prone the tree is to canker and how poor the quality is in some districts, I decided to include it in my condemned list. This variety is in season with Blenheim Pippin and Cox's Orange Pippin, and, being inferior to both in quality, was another reason for discarding it. Bess Pool has no particular merit in flavour; high colour is its great asset. Mank's Codlin is too small; besides, we have Keswick Codlin, Grenadier, Lord Grosvenor, Lord Suffield, and, above all, the newer Rev. W. Wilks, which will cut out several other sorts when its wonderful cropping qualities become better known. Any one of those mentioned are superior to Mank's Codlin in every respect. I retained New Hawthornden in the place of the older variety as the latter is too prone to scab and other diseases. My experience in the North of England is that Lord Suffield is far superior to Domino. Duchess's Favourite is too small and is in season with others that are superior to it. Doubtless there are many other sorts not required. In all cases where new plantations of Apples are made, numbers of one or more well-tried sorts, such as Bramley's Seedling, Newton Wonder, Nortolk Beauty, Cox's Orange Pippin, and James Grieve, should be included in the selection. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham.*

Mr. E. Molyneux has rendered a public service in drawing attention to the large number of undesirable Apples which are so freely grown. Considering the wealth of reliable varieties, both of culinary and dessert Apples, it is surprising that valuable space should be allotted to sorts that have no special merit. Mr. Molyneux will not be surprised to find some adverse friendly criticism as to those condemned by him, for certain varieties do remarkably well in one locality, and are practically failures in others. Generally, I am in agreement with his list of undesirables, with the following exceptions: King of the Pippins is, in my opinion, one of the very best dessert Apples. The tree makes a shapely specimen, especially as a pyramid or bush. With us this variety rarely fails to produce good crops. The fruit is of medium size, of pleasing appearance, good in flavour, and is at its best in mid-winter. Red Astrachan is one of the best early Apples here. The fruits are of good appearance and have a nice flavour, but must be eaten directly after they are gathered. Scarlet Nonpareil is a valuable late variety, with a flavour of its own. The tree is a constant bearer. When properly kept the fruits are at their best condition at the beginning of March. More surprising, in my opinion, is the large number of worthless Pears which are cultivated in this country. If something could be done to reduce both the list of Apples and Pears it would be a boon to all concerned. *Edwin Beckett, Udenham House Gardens, Elstree, Hertfordshire.*

ALEYRODES (WHITE FLY) (see p. 108).—We have been troubled with White Fly for the past two seasons, and fumigating with nicotine preparations has had no effect other than causing the insects to drop off the plants, to return again as soon as air is admitted in the morning. During the past winter I have fumigated several times with cyanide. I use sodium cyanide ¼ oz., phosphoric acid ¼ oz., and 1 oz. of water for each 1,000 cubic feet. This strength will kill all fully developed insects, but it is absolutely essential to fumigate again after an interval of a week or 10 days, as by that time other insects will have hatched out, and the fumigating should be continued until all the eggs have hatched. No plants have been injured at the above strength, even young fronds of Adiantum Ferns being unharmed. It is essential that the cyanide should be broken into pieces not larger than a Pea. The water should be placed in the receptacle before the acid. *G. H. Head, Fulwell Park Gardens, Twickenham.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 12.—The exhibition on Tuesday last followed much the same lines as the preceding ones of the present year, and was of about the same size as the last show, the only difference being that there were more Daffodils. The only awards made to novelties were recommended by the Orchid Committee, namely, two First-class Certificates and three Awards of Merit.

The Floral Committee awarded medals to eight groups. The best exhibit in this section was Messrs. ALLWOOD BROS.' collection of Perpetual-flowering Carnations. Messrs. H. B. MAY AND SONS again contributed a handsome exhibit of Ferns interspersed with groups of flowering plants such as Cinerarias and the grandiflora strain of Primula obconica. A mass of the climbing Banksian Rose was shown by Mr. GEO. PRINCE. Mr. G. W. MILLER exhibited some uncommonly good coloured Primroses and Polyanthuses in a general collection of hardy spring flowers, and a magnificent truss of Clivia Baroness Schröder, a fine orange-red variety.

Mr. L. R. RUSSELL staged well-flowered Wistarias, the floriferous Prunus triloba, and a number of Azaleas, set off by an edging of Tradescantia multicolor. Messrs. R. TUCKER AND SONS again showed Saxifrages in variety. Mr. G. REUTHE had also a number of Alpines, together with choice shrubs in pots and a number of Rhododendrons, including R. quinquefolium, a deciduous species with flattish blooms of a delicate blush shade, and R. lutescens, with numerous small, sulphur-yellow flowers. Messrs. R. GILL AND SONS also showed Rhododendrons. Their exhibit was principally composed of garden hybrids of the arboreum type; there were also good trusses of R. grande and R. ciliatum, set off by massive foliage, in separate vases, of R. Falconeri. In addition to Rhododendrons they showed vases of Polyanthus Pompadour, the finest crimson variety. Messrs. PIPER AND SON'S exhibit included pot plants of Olearia ramulosa, with starry, white flowers, like those of Aster ericoides.

The Fruit and Vegetable Committee recommended a Gold Medal for an exhibit of preserved fruits and vegetables shown by Mr. VINCENT BANKS on behalf of the bottling and drying section of the Food Production Department (Board of Agriculture). This exhibit may be said to be the finest of its kind ever staged at an R.H.S. meeting.

Floral Committee.

Present: Messrs. H. B. May (chairman), John Heal, W. B. Cranfield, G. Reuthe, S. Morris, J. W. Barr, C. R. Fielder, W. J. Bean, John Green, G. Harrow, E. F. Hazelton, C. E. Shea, A. Turner, J. W. Moorman, C. Dixon, J. Dickson, C. E. Pearson, W. P. Thomson, G. Paul, J. Jennings, E. H. Jenkins, R. W. Wallace, A. G. Jackman, and H. Cowley.

GROUPS.

The following medals were awarded to collections:—

Silver Flora Medal to Messrs. ALLWOOD BROS. for Carnations.

Silver Banksian Medals to Messrs. H. B. MAY AND SONS for Ferns and flowering plants; Mr GEO. PRINCE for Roses; Messrs. R. GILL AND SONS for Rhododendrons; Mr L. R. RUSSELL for flowering shrubs; and Mr G. W. MILLER, for spring flowers.

Bronze Flora Medals to Mr G. REUTHE for hardy plants and shrubs, and Messrs R. TUCKER AND SONS for Saxifrages.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. sec. pro tem.), Gurney Wilson, W. Bolton, R. A. Rolfe, F. Boreham White, S. W. Flory, Walter Cobb, W. H. White, Pantia Ralli, T. Armstrong, Frederick J. Hanbury, R. G. Thwaites, J. Wilson Potter, W. H. Hatcher, and Fred. Sander.

AWARDS.

FIRST-CLASS CERTIFICATES

Cattleya Clotho var. General Pershing (*Enid* × *Trianae Grand Monarch*), from Messrs CHARLESWORTH AND CO.—An ideal flower, and one of the best, from a florist's point of view, ever raised. The finely proportioned flower has crimped petals, 3½ inches wide, and of pale rose colour; the equally broad and openly displayed lip is violet-crimson, with gold lines from the base.

Odontioda Windsor (see fig. 53) (*Oda. Sanderæ* × *Odm. illustrissimum*), from Messrs. FLORY AND BLACK.—A grand hybrid, equal in size and shape to a good Odontoglossum crispum, but the colour is scarlet with slight white markings on the margins and tips of the segments. The lip is mottled with light red, and there is a dark red blotch in front of the yellow crest.

AWARDS OF MERIT.

Sophro-Cattleya Mrs. J. Ansaldo (*S.-C. warnhamiensis* × *C. Empress Frederick*), from J. ANSALDO, Esq., Rosebank, Mumbles.—A pretty flower of good size, and in shape nearest to Cattleya. The sepals and petals are a delicate salmon colour with a rose shade; the lip, which has a wavy margin, is coloured purplish-rose with gold lines from the base.

Odontioda Alcantara var. rubra (*Oda. Cooksoniæ* × *Odm. eximium*), from Messrs. CHARLESWORTH AND CO.—A showy flower of a deep ruby-red colour with yellow crest to the lip.

Cattleya Cappei alba (*Schroderæ alba* × *Trianæ alba*), from Messrs. ARMSTRONG AND BROWN.—The flower is of large size and has the broad proportions of C. Schroderæ; it is clear white with a light yellow disc to the lip, and in general characters near to C. Lady Veitch.

CULTURAL COMMENDATION.

To Mr. Thurgood, gardener to H. T. PITT, Esq., Rosslyn, Stamford Hill, for a fine specimen of the rare Neo-Moorea irrorata, with two well-developed spikes.

GROUPS.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Flora Medal for a group in which were several excellent new hybrid Odontoglossums and Odontiodas flowering for the first time. Among the more notable plants were Odontioda Mars (Oda. Bradshawiæ × Odm. Mars), a large and finely-formed flower with the inner two-thirds of the segments heavily blotched with vinous red on a cream-coloured ground; Odontoglossum Nora var. Harlequin (illustrissimum × Dora), a large, white bloom, beautifully blotched with claret colour; and O. King Albert (crispum × Armstrongiæ), with violet-purple markings. The Cattleyas included C. Trianæ Edgar Knight, with rich purple lip like that of C. T. Imperator, and broad rose petals with the purple feather of C. T. Backhouseana.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for an excellent group, principally of Odontiodas and Odontoglossums. The interesting and pretty Epiphaella Rolfei, with clear, rose-coloured flowers, and the new Odontonia Irene (M. Warscewiczii × O. hastilabium), with dark purple sepals and petals and blush-white lip, were attractive features.

Mrs. F. M. OGILVIE, The Shrubbery, Oxford (gr. Mr. Balmforth), was awarded a Silver Banksian Medal for a small but select group of finely-flowered Orchids, which included a plant of Odontoglossum Ceres Fowler's variety, with a fine spike of flowers; Cattleya Trianæ Moore Jane, C. T. Mafeking, and C. T. Rajah, the last-named being by far the best.

Messrs. HASSALL & Co., Southgate, were awarded a Silver Banksian Medal for a group of Cymbidiums, among which were two clear canary-yellow forms, a welcome variation from the usual type.

Messrs. SANDERS, St Albans, were awarded a Silver Banksian Medal for a group principally of hybrid Cymbidiums. Laelio-Cattleya Elfin (*C. Luddemanniana Stanleyi* × *L.-C. Canhamiana Rex*) has white sepals and petals and a violet blotch on the lip, which has a broad white margin.

Messrs. FLORY AND BLACK, Slough, showed several new hybrids, including Odontoglossum Rosslyn (Rolfeæ × illustrissimum), with large white flowers attractively marked with dark purple; Sophro-Laelio-Cattleya Beta (S.-L. Psyche × C. Maggie Raphael alba), of a clear Buttercup-yellow colour, and the white Cattleya Oenone alba.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Rev. J. Jacob, Messrs. W. Poupart, W. B. Cranfield, Herbert Chapman, J. D. Pearson, G. Reuthe, W. F. M. Copeland, and C. H. Curtis (hon. sec.).

Messrs. R. H. BATH, LTD., exhibited two groups, in the one case a fine display of Tulips, chiefly Darwin varieties, grown in fibre, the other of Narcissi. The Tulips scarcely made so fine a display as at the previous meeting. Nevertheless it was a very useful contribution, and the bowls of Le Rêve, Andromache, Flamingo (a possible rival to Clara Butt), Cramoise Royal, Rev. Ewbank, and Princess Hélène were especially good. The group of Daffodils included fine blooms of White Slave, Silver Dawn, The Fawn, and Evangeline. (Silver-gilt Flora Medal.)

Messrs. J. R. PEARSON AND SONS contributed a good exhibit of Daffodils, in which Giant Leedsii varieties were a feature. A few of the best flowers were Louise Linton, Norah Pearson, Florence Pearson, Vega, Whitewell, Great Warley, Madame de Graaff, and King Alfred. (Silver Flora Medal.)

Fruit and Vegetable Committee.

Present: Messrs. J. Cheal (in the chair), W. Poupart, W. Bates, Edwin Beckett, A. R. Allan, G. Reynolds, Owen Thomas, W. H. Divers, E. A. Bunyard, W. Wilks, and G. P. Berry.

Messrs. J. CHEAL AND SONS showed dishes of late-keeping dessert Apples, including Cornish Aromatic, Brownlees' Russet, Sturmer Pippin, Boston Russet, and William Crump. The flavour of Brownlees' Russet was very good, but Cornish Aromatic was past its best stage. William Crump was the handsomest variety, but although the flavour was excellent the mealy flesh showed that it was no longer in first-rate condition.

A collection of autumn-sown Beets was exhibited from the Society's gardens at Wisley. The trial proved that varieties of the long-rooted type are of no value for winter cropping, but that the Egyptian, or Turnip-rooted sorts, are capable of standing the winter well, and are tender, the flesh being free from fibre, which develops in the tap-rooted kinds.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

ANNUAL MEETING.

APRIL 11.—The annual meeting of this Provident Society was held in the Royal Horticultural Hall on Monday, the 11th inst., Mr. Charles H. Curtis presiding.

The annual report of the Committee stated that the Society continues to flourish. The chairman pointed out that the Committee dealt in the most sympathetic manner possible with those members who, having served their country in the fighting line, came home injured but omitted to claim benefits immediately after landing. The turnover for the year was £4,873 on the ordinary side: £2,000 was invested, and £1,763 15s. 6d. paid out in benefits, etc. The cost of management was £50 18s. 6d.; the sum of £206 6s. 8d. was paid in sick pay to wounded soldiers and sailors. Thirty-four members have been killed in action, and the sums paid to their nominees amounted to £244 3s. Reference was made to the establishment of a juvenile branch, and to the loss sustained by the death of Mr. Leopold de Rothschild, patron of the Society, and Mr. Wm. Marshall, who, with the late Mr. Shirley Hibberd, was a founder of the Society.

After the adoption of the report and accounts thanks were accorded to the trustees, Messrs. Jas. Hudson, Riley Scott, and C. H. Curtis. For 36 years Mr. Jas. Hudson had made the chief investments of the Society, and during that time has seen the investments rise from £2,000 to £52,800. A letter from the Society's brokers referred to the splendid financial position of the Fund and the security of its investments. Mr. A. C. Hill was reappointed

secretary, Mr. Thos. Winter was re-elected treasurer, and the retiring members of Committee, Messrs. A. C. Bartlett, T. R. Butler, A. E. Cresswell and E. F. Hawes, were re-elected.

Sir Harry J. Veitch has consented to become a patron in the place of the late Mr. Leopold de Rothschild.

BRITISH GARDENERS'.

MARCH 8.—A meeting of the British Gardeners' Association was held in St. Stephen's Hall, Coventry, on Friday, the 8th inst. when Mr. Cyril Harding explained the aims and objects of the Association, which is now a recognised trade union.

He made reference to the long hours, low rates of wages, and other disadvantages under which the gardener laboured, as compared with other skilled workers. He emphasised the necessity of professional gardeners being organised to make good their demands, and wound up with a spirited appeal to all horticultural workers to become members of the Association.

Mr. Harding stated that the chief objects of his society were to secure a complete organisation of all horticultural workers; to improve the conditions of labour; to secure reasonable working hours and higher rates of wages; to settle disputes between employers and employees; to provide temporary assistance to members when out of employment; to obtain proper hothy and housing accommodation; a compulsory character note; and a weekly half holiday and payment for overtime. At the close of the meeting a Coventry branch was formed and over twenty members enrolled.

CROPS AND STOCK ON THE HOME FARM.

SAINFOIN

THE recent order that all land carrying Sainfoin over five years old must be ploughed and sown with corn will considerably reduce the acreage of this valuable hay crop and sheep feed in this country. Sainfoin is much favoured for the best type of hay for sheep and horses in districts where it succeeds well. In some cases Sainfoin leys when over five years old are worn out; other fields of this crop last longer. The condition of the land when the seed was sown is the governing factor of how long Sainfoin will continue profitable. No matter how small a quantity of Couch the land contains, that Couch spreads quickly, and in time the grass smothers the Sainfoin so effectively that its life of serviceable use is limited. The present price of seed being eight guineas per quarter, there is not much encouragement to sow more land with this crop. Still, Sainfoin is valuable feed, and there are many who are sowing. The present dry weather affords a good opportunity of getting in the seed on autumn-sown Wheat or along with Oats or Barley. In all cases the recent frost has pulverised the soil sufficiently to provide a perfect filth for a seed bed. If sown with Wheat it should be done crosswise to the Wheat drills, so that the harrowing of the Wheat in front of the drill and afterwards will not drag up too many of the Wheat plants. With the ordinary corn drill sow 4 bushels per acre of Sainfoin, following the harrows after the drill and rolling behind to make the seed and Wheat plant firm. When sown with Oats or Barley the seed should be drilled, it matters not in which direction. The harrowing necessary for the corn serves for the Sainfoin too.

TREFOIL AND ITALIAN RYE GRASS

For sheep that are kept mainly on arable land throughout the year a mixture of Trefoil at the rate of 6 lbs. per acre and 1 bushel of Italian Rye grass provides much useful green food for ewes and lambs in June of the following year. If not required then, owing to other foods being plentiful, an extra crop of hay is assured. The seed is sown with Oats or Barley, the harrowing necessary for these cereals benefiting also the grass seeds when sown by the aid of a separate hand seed harrow.

PREPARING THE LAND FOR MANGOLD, CABBAGE AND POTATOES.

THE present fine weather should be utilised for getting fallow land into a workable condition for these crops to be sown and planted in April. Cross-ploughing stiff soil disintegrates the clods and disturbs Couch and other weeds which may be troublesome later if not interfered with before sowing time arrives.

TRIFOLIUM INCARNATUM.

CRIMSON Clover, intended to provide green food for horses, cows, and pigs during May and June, is generally looking promising. Where the plant shows a tinge of chlorophyll or green colouring matter in the leaves and general weakness it should be assisted by the application of sulphate of ammonia sown evenly at the rate of 1 cwt. per acre on a dry day when dew is on the leaves. *E. Molyneux.*

COUCH AS FOOD FOR STOCK.

EXPERIMENTS are being made to determine the value of dried Couch grass as fodder, and the Board of Agriculture and Fisheries suggest that farmers whose land is foul should collect the Couch grass and instead of burning it should store it when dry. Should the Couch grass be found as the result of the experiments to be unsuitable for feeding alone, it would be of use in view of the shortage of feeding stuffs, to mix with other fodder, and, in any case, if shortage of labour and other circumstances preclude its utilisation in this way, it can afterwards be burnt as is now done, or better still, rotted down for manure.

THE LATE MR. HERBERT J. CUTBUSH.

CONDITION OF THE CROPS.

THE crop reporters of the Board of Agriculture, in reporting on agricultural conditions in England and Wales during February, state that the autumn-sown Wheat is everywhere looking well and promising, especially in the West, where in a few places it is regarded as being almost too forward. Winter Oats are generally also a good and promising crop. Beans are rather more variable, the plant being thin in a few districts, but otherwise healthy and satisfactory. The weather during February was very favourable to field work, having been universally mild and open, though with rather too much rain in some of the northern districts. Ploughing and cultivation accordingly made rapid progress, and much spring Wheat was got in under favourable conditions. Wheat sowing is not yet completed, and another 10 per cent. of the total Wheat area probably still remains to be sown, but this work is more nearly finished in the east than in the west. In most districts some Oats and Barley have also been got in, but the seeding of these cereals is generally only just beginning. Spring work is well forward for the time of year.

Seeds are, except in the north-eastern side of the country, where they are often thin owing to the dry summer last year, a good plant, growing well, and giving satisfactory promise. A considerable has in most parts of the country been ploughed up for corn, so that it may be safely said that the total area under Clovers and rotation grasses will be somewhat reduced.

Obituary.

HERBERT J. CUTBUSH.—We announce with deep regret the death of Mr. Herbert J. Cutbush, head of the firm of Messrs. Wm. Cutbush and Son, nurserymen, Highgate and Barnet. He died on Thursday, the 14th inst., after a long illness, aged fifty-three years. When a young man Mr. Cutbush was called upon to take charge of the nursery business in succession to his father, whose early decease will be remembered by many of our readers. Mr. Herbert Cutbush showed great energy, and in conjunction with his brother, Mr. William Cutbush, built up a large business, especially in landscape gardening, hardy plants, fruit trees, Roses and Carnations. The firm's exhibits at all the leading London and provincial shows made the name of Cutbush more famous than it had ever been; the good humour and pleasing personality of Mr. Herbert Cutbush did as much as the exhibits to place his firm in the forefront. Some years ago Mr. Cutbush was taken ill, and though there was partial recovery for a time he was eventually confined to his home, leaving the conduct of the business in the hands of his brother and his son, Mr. Leonard Cutbush. Although death came as a happy release from long suffering, a large circle of friends and acquaintances will mourn the loss of a genial and business like man who had the habit of always looking at the bright side of things. He died at his residence, Normanhurst, Broadlands Road, Highgate, and his remains were interred at Highgate Cemetery on Monday, the 11th inst. The funeral service was held at St. Michael's Church, Highgate.

WILLIAM CLARK.—We regret to announce the death of Mr. William Clark, nurseryman, Carlisle, who has recently died at the age of seventy-four. He was born near Tayport, in Fifeshire, and began his professional career in a Dundee seed business, after one or two changes becoming manager to Messrs. Little and Ballantyne, of Carlisle. Forty-five years ago he started a business in the same city in conjunction with his brother, a business which has flourished and finally became one of the largest in the district. Mr. Clark was one of the first English nurserymen to export Gooseberry bushes to America, and for some years did a large trade with the United States. He was also an authority on forest trees, and in 1886 gained the first prize and silver medal of the Royal Arboricultural Society for an essay on diseases of the Larch and Pine. Five years ago the firm was converted into a private limited company, when Mr. Clark retired from active participation in the business. He is survived by his widow and one son.

THOMAS TYRER.—We regret to learn of the death of Mr. Thomas Tyrer, head of the well-known firm of insecticide and other chemical manufacturers, at Stratford. He died suddenly on February 20, aged seventy-five. Deceased was educated at the Royal College of Science, and was for many years consulting chemist in the firm of May and Baker, of which he was eventually managing director, but for nearly twenty years before his death he conducted his own business with conspicuous success. He was a member of the council of the Association of British Chemical Manufacturers, and on the executive of the National Physical Laboratory. He had a wide and intelligent outlook, and did much to serve the interests of chemical science in this country.

MARKETS.

COVENT GARDEN, March 13.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—Eds.

Plants In Pots, &c.: Average Wholesale Prices.

	s. d.	s. d.		s. d.	s. d.
Adiantum	4 0– 5 0		Cyclamens	21 0–24 0	
Araucaria excelsa	7 0– 8 0		Cineraria	10 0–12 0	
Asparagus plumosus	10 0–12 0		Erica persoluta	36 0–42 0	
— Sprengeri	9 0–10 0		— Wilmoreana	30 0–36 0	
Aspidistra, green	36 0–42 0		Genistas	18 0–24 0	
Ferns, in variety	18 0–24 0		Marguerites, white	9 0–10 0	
			Mignonette	12 0–15 0	

REMARKS.—More business is being done in pot plants this week. Ferns are of much better quality, and flowering plants are receiving more attention. Pink and white Hydrangeas are being offered.

Ferns and Palms Average Wholesale Prices.

Cut Foliage, &c.: Average Wholesale Prices.

	s. d.	s. d.		s. d.	s. d.
Adiantum (Maidenhair Fern) best, per doz. bun.	8 0–10 0		Berberis, per doz. bun.	6 0– 8 0	
Asparagus plumosus, long trails, per half-dozen	2 6– 3 0		Carnation foliage, doz. bunches	4 0– 5 0	
— — medium, doz. bunches	1 8–2 1 0		Cycas leaves, per doz.	3 0– 6 0	
— Sprengeri	10 0–15 0		Fern leaves, per doz. bunches	2 0– 2 6	
			Moss, gross bun.	7 0– 8 0	
			Smilax, per bun of 6 trails	2 0– 2 6	

REMARKS.—White flowers are again increasing in value. Lilium longiflorum and Richardias (Arums) have advanced considerably in price this week. Lily-of-the-Valley is reduced in quantity, which has caused a further increase in price. Coloured flowers show little change from last week. Carnations are sufficient for the demand. Roses, although more plentiful, are not much cheaper at present. Violets from the Channel Islands have been irregular during the last week, and consignments are smaller. The non-arrival of French flowers caused disappointment to many buyers on two or three days of last week. Paper-white Narcissus appear to be nearly over, and there are very few white flowers to take their place. However, White Stock and Star of Bethlehem (Allium) should be more plentiful in a few days.

Vegetables: Average Wholesale Prices.

Fruit: Average Wholesale Prices.

	s. d.	s. d.		s. d.	s. d.
Almonds, per cwt	170 0 —		Grapes, con.— — Gros Colman, per lb	4 0– 9 0	
Apples:— — English, per bus.	25 0–30 0		Lemons, per case	38 0– 46 0	
— Russets, French, in case of about 60 to 70 lbs.	50 0 55 0		Nuts, Barcelona, per bag	150 0 —	
Dates, per box	1 7– 1 8		— Cob, per lb	1 9–1 10	
Grapes, Black Alicante, per lb.	4 0– 6 0		Oranges, per case	42 0–130 0	
— Almeria, per barrel (½ doz. lbs.)	50 0–70 0		Strawberries, forced, per lb.	15 0–20 0	
			Walnuts, kiln dried, per cwt.	100 0–110 0	

REMARKS.—Apples are now much scarcer. Forced Strawberries are available in limited quantities. English Grapes are limited in supply, and Spanish kinds are more in demand. Forced Marrows are now on offer. Other forced Vegetables obtainable are Dwarf Beans, Asparagus, Endive, Mushrooms, Cucumbers, Seakale, Mint, New Potatoes, and Peas. The market is fairly well supplied with outdoor vegetables and roots. *E. H. R., Covent Garden Market, March 18, 1918.*

THE WEATHER.

THE WEATHER IN SCOTLAND.

For the greater part of February the weather was mild, dull, and showery, but the temperature fell sharply on the last day, when a severe blizzard heralded the advent of spring. The total rainfall was 2·15 inches, but showers were so frequent that there were only five days on which no rain was collected, the greatest fall on one day being 0·53 inch on the 17th. Sunshine was very meagre, a total of 61·2 hours for the whole month, being an average of 2·2 hours per day, and a percentage of — The highest barometric pressure of 30·57 inches was recorded on the 25th, and the lowest of 29·75 inches on the 9th, while the mean for the month was 29·95 inches. The mean temperature was 41·5°, with a mean range of 10·4°, and an absolute range of 27°. On the 22nd the highest maximum reading of 57° was obtained, and on the 1st the lowest minimum of 30°, while the lowest maximum and highest minimum of 36° and 45° respectively were registered on the 28th and 23rd. On the grass the mean minimum temperature was 32°, with a lowest of 24° on the 1st. There were eleven nights of ground frost. At 1 foot deep the mean soil temperature was 38·8°, rising during the course of the month from 38° to 41°. The ground was clear of snow till the 23rd, when heavy drifting accompanied a fall which lasted from 9 a.m. to 11 p.m. The prevailing winds were southerly, more so in the afternoons, and westerly. *James Mallach, Director of Studies, St. Andrews Training College Gardens, Kirkton of Maines, near Dundee.*

GARDENING APPOINTMENT.

MR. GEO. MILLER, recently discharged from the London Scottish Regiment, previously Gardener to Mrs. GOODMAN, Alyth Bank, Clapham Park, and formerly of Tring Park, Compton Place, Eastbourne, Cumberland, as Gardener to the Earl of LICHFIELD, Shugborough Hall, Stafford.

ANSWERS TO CORRESPONDENTS.

BLETIA HYACINTHINA: *Ignorant.* As the plant is happily established, why not leave well alone? If it is necessary to enlarge the plantation, the best way to increase the stock is by division just before growth commences. Take up the plant, pull it apart, and place the pieces in small pots filled with a mixture of loam and leaf-mould, with plenty of material for drainage. Grow the plants in a close, cool frame until the roots are re-established, and then gradually admit more air and harden them off for planting outside.

BLUE HYDRANGEAS: *F. J. H.* In order to obtain Blue Hydrangeas it is first essential to make sure that the soil in which the plants are growing is free from lime, chalk, or any other calcareous substance. Water the plants with rain-water and add to it about a quarter of an ounce of sulphate of iron or sulphate of ammonia to the gallon.

CALORIC VALUES: *G. H. H. W.* 1 lb. of Potatos (edible part only) = 385 calories; 1 lb. Haricot Beans = 1,580 calories; 1 lb. beef (best parts) = 1,100 calories (down to about 750 for skin, etc.). In making calculations of this kind the amount produced from a certain area of ground in a certain time should, of course, also be taken into consideration.

EARLY-FLOWERING PLANTS DAMAGED BY INSECTS: *Dorset Gardener.* The damage may be caused by small black slugs or woodlice. Woodlice can be trapped in pots filled with hay placed near the plants. Slugs may be kept away by sawdust, as recommended on p. 108.

NAMES OF FRUITS: *J. E. W.* Apple Herefordshire Pearmain; Pear Vicar of Winkfield. Most stewing Pears decay in the same manner as your fruits.—*Editha Jamieson-Grist* Calville Rouge.—*H. E.* Old Nonpareil.

PLUMS IN POTS: *I. S.-E.* The varieties of Plums you name—Jefferson, Denniston's Superb, Quillin's Golden Gage, Coe's Golden Drop, and Victoria—are all good bearers, and you should have no difficulty in the fruits setting freely. Constant attention must be given to the ventilation of the houses whilst the trees are in blossom. Do not allow the house to be absolutely closed for any length of time, and then only in frosty or windy weather. Plums, on the whole, do better in a slightly lower temperature than is necessary for Peaches. If the Plum trees are growing in a span-roofed Peach house, arrange them on the northern or eastern side, away from the direct rays of the sun. If they are large specimens, give them a sharp tap every day when the atmosphere is quite dry to distribute the pollen. The flowers can be brushed with a rabbit's tail to pollinate them, but the best means of ensuring the fruits setting is to place a hive of bees in the house. Keep the atmosphere dry, and I do not allow the night temperature to exceed 45° to 50°, the lower degree being preferable.

POTATOS IN SUCCESSIVE YEARS: *Delta.* If you thoroughly dig the ground, remove all old tubers, burn the weeds and haulm left over from last year, and apply plenty of manure, there is no reason why you should not have a good crop of Potatos again this season. We know of instances where Potatos have been successfully grown on the same plot for thirty years without a break.

WASTE FROM A TANNERY: *H. E.* The sample of tannery waste is of some fertilising value, but its mechanical condition is very rough, and it would want drying and breaking up before it could be used. The material sent contains a fair amount of lime, which is distinctly useful on the land, and also a quantity of hair, which is of less fertilising value. It is not possible to say how much the material is worth from the sample sent, as it is impossible to tell from this how much water is present in the bulk. Generally speaking, these residues are worth haulage, but not a great deal more.

THE HISTORY OF CULTIVATED FRUITS.

AS TOLD IN THE LIVES OF GREAT POMOLOGISTS.

ROBERT THOMPSON.

IT has been said that the world knows little of its great men, and in few cases is the assertion truer than in that of Robert Thompson. His work as a Pomologist, especially in the rectification of nomenclature, places him in the front rank; in my opinion he is our greatest British Pomologist. A man of singular modesty, he preferred to work behind the scenes, and so long as he could bring order into chaos he seemed to care little who obtained the credit for such work. Lindley, London, and Dr. Hogg, to mention a few names only, owed much to his painstaking study of fruits, and used it in their own publications, not always with the acknowledgment that was his due. Of Thompson's history not much is known: short obituary notices in the *Gardeners' Chronicle* and in the *Journal of Horticulture* published shortly after his death comprise all the printed information I have been able to discover; but through the rule that held at Chiswick, under which all entering the Garden of the Royal Horticultural Society recorded in a book an account of their lives to date, I was enabled to find authentic information as to his early career. The entry runs as follows:—

"Robert Thompson, admitted October 21, 1821, upon the recommendation of Sir R. Fergusson. I was born in the year 1799, in the parish of Echt, in the county of Aberdeen, where my father had a small farm. From five years of age, and when fourteen I was with my uncle, who was gardener to Mr. Skene of Skene. I was part of the time, from 1813 to 1819, at school, and occasionally employed in the garden and plantations belonging to the gentleman above mentioned. I then worked at the gardens at Haddo House, the seat of the Earl of Aberdeen, until November, 1820, when I went to Lord Kennedy's gardens at Dunnottar, where there one year, and in November, 1821, I went to the gardens of Robert Fergusson, Esq., of Raith, where I worked for nearly three years, and on leaving that place I came to the Garden of the Society, being twenty-five years of age and unmarried. *Robert Thompson.*"

Chiswick at that date devoted very considerable attention to fruits, and the large collection of trees was just coming into bearing, so Thompson, being put in that department, had an admirable opportunity for study. The careful work on revising hardy fruits, *The Catalogue of Fruits cultivated in the Garden of the Horticultural Society at London*. The first edition of this work was published in 1826 and was not much more than a list of

ROBERT THOMPSON.

names. In the second edition of 1831 the synonyms had largely been worked out and brief descriptions were added. When it is realised that some 1,400 Apples, 219 Cherries, and 677 Pears are dealt with, to mention no other fruits, it will be seen that Thompson's first seven years at the Gardens were well occupied. The Society, in their preface, generously acknowledged that whatever merit the catalogue possessed was due to Thompson, who at that time (1831) was in charge of the Fruit Department. The third edition of the catalogue appeared in 1842 and was reduced by the omission of many worthless sorts, and the synonyms being given in italics in their alphabetical order greatly facilitated reference. The great amount of work this publication entailed can only be appreciated by those who have attempted a similar task, and the evidence still happily exists in the MS. drawings of fruits in the possession of the Society, in which the process of revision can be traced.

In 1827 the publication of the *Pomological Magazine* was commenced, and in this Thompson had some part, though how much it is difficult to discover. In the [illegible] of the Apple Court Pendu Plat he [illegible] as "a young man of first-rate [illegible] in his profession, to whose good [illegible] practical knowledge we are [illegible] take this opportunity of expressing [illegible] gratification for assistance in the production of [illegible] work." This work was [illegible] 1841 as the *Pomologia Britannica*, but the text was unchanged, so Thompson appears again as a "young man." In 1842 London published a new edition of his great *Encyclopædia of Gardening*, and to this Thompson prepared revised and enlarged descriptions and classifications of the fruit sections, which work was duly acknowledged by London in the preface. A great deal of Thompson's work for the Royal Horticultural Society is to be found in the *Transactions*, and in Series 2, Vol. I., are his excellent monographs on the Apricot, Gooseberry and Cherry, models of careful and painstaking work. From this and other work it would seem that Thompson had some knowledge of French and German, or was at least assisted in this direction, as references to French and German literature are frequent and reliable.

The work, however, with which his name will always be associated is the *Gardener's Assistant*, the "Gardener's Bible," as it has been termed. This was published in 1859. This work was almost entirely his own production, and it is difficult even to-day to find in one cover so much sound information conveyed in a clear and ordered manner. With all respect for recent editions, I must confess a preference for the work as it came from the master's hand, and in matters of culture it can yet be profitably consulted. The descriptions of fruits are excellent within their limitations; in many cases tree characters are described, and in all we find the salient characters selected with judgment. A glance through the 774 pages reveals the author as more than a fruit specialist. Every subject is treated with authority; we find a trace of Lindley's pontifical manner in the early chapters on physiology of plant life, but nearly all has the true ring of the man who has worked before he wrote.

Of Thompson's work in the periodicals of the day it is not so easy to speak. He contributed to the *Suburban Horticulturist*, *Penny Cyclopædia*, *Cyclopædia of Agriculture*, Moore's *Treasury of Botany*, the Edinburgh *Philosophical Magazine*, etc. His articles in the *Gardeners' Chronicle* were not signed, but may be recognised by the double dash (——) which was all his modesty allowed. From this mark we gather he was the chief authority referred to by the paper for many years in matters of fruit nomenclature. He retired from the employment of the Horticultural Society in April, 1868, on full pay, and so towards the end of his life presented with a purse of £100 raised by public subscription. His death occurred in 1869. By the kindness of Mr. Barron Wyatt I am able to conclude this article [illegible] very in-

* Previous articles appeared in our issues for June 14, July 26, and August 30, 1913, May 2, November 5 and 26, 1914, June 12, and September 4, 1915.

teresting note, which very happily preserves for us a picture of Thompson as he appeared in his latter days; and I am also obliged to him for the loan of the portrait, this being, I believe, the first time that it has been reproduced. *E. A. Bunyard.*

"I left Shrewsbury on the morning of March 26, 1836, changed trains at Reading, from the Great Western to the London and South-Western Railway, and landed at Chiswick station somewhere about 10 p.m., long after the gardens were closed. I was in need of food and shelter for the night, and the station master at Chiswick kindly took care of my few belongings and gave me a note of introduction to an innkeeper in the village, about a mile away, who equally kindly welcomed a stranger within his gates. He enquired where I was bound for on the morrow, and on learning my destination, said, 'Oh, that's all right. Go into that room and you will find Mr. Thompson there; make yourself known to him, while I get you some supper.' I found an old gentleman sitting by the fire smoking the favourite 'church-warden' of those days. He was very silent and reserved at first, but presently thawed, and then I found myself in the presence of the great man, the author of *The Gardener's Assistant*, in his usual somewhat shy but most amicable mood. He locked me up in the garden the next day, and the friendship ripened. For some forty or more years Mr. Thompson had compiled a series of daily meteorological records at the gardens, and it became my pleasure later, when he became too enfeebled to come to the garden night and morning regularly, to take the records for him. His little office was next door to the bothy allotted to me when Mr. Barron promoted me to be foreman of the fruit department, and all old Chiswick men will remember the bothy at the back of the early vinery. My change of quarters led the old gentleman often to come and spend an hour or two and smoke his pipe with me, before taking his records at 9 p.m. His knowledge of gardening was encyclopædic, and when questioned on any subject his answers were concise and to the point; but they were always given guardedly, and seldom without the preliminary proviso 'I think.' Mr. Barron used to claim for him that he was the greatest living authority on fruits, but when acting as pomological referee to *The Gardeners' Chronicle*, as he did for many years, he never was dogmatic in his identifications, but although quite certain in his mind, almost invariably prefaced the name with 'I think this is,' or 'we think this is' so-and-so. From Mr. Thompson I learnt a great deal concerning the early history of the Royal Horticultural Society and of the origin of Dr. Hogg's *Fruit Manual*, which was based on Mr. Thompson's records and descriptions, then kept in the old fruit room at Chiswick. But that is another story; certain it is that owing to his shyness, extreme reserve generally, and Scottish caution, justice has never been done to him for the splendid work he did for British pomology at Chiswick." *Brian Wynne*

Fig. 55.—CYNORCHIS PURPURASCENS.—FLOWERS ROSY PURPLE.

ORCHID NOTES AND GLEANINGS.

CYNORCHIS PURPURASCENS.

CYNORCHIS PURPURASCENS (see fig. 55), a terrestrial Orchid with a solitary leaf 2 feet long and 3 inches wide, and a stout peduncle one foot long bearing a large, globose head of showy rosy-purple flowers, is as remarkable among its kind as the great monophyllous Streptocarpus Dunnii is among Gesnerads. Both plants made their début at Kew, the latter in 1836, when its leaves, 3 feet by 16 inches, sprawled over a gravel bed in the Succulent House, causing quite a botanical sensation; the former in 1902, when Sir Joseph Hooker described the plant as the largest-leaved Orchid known. The species was introduced from Madagascar by Mr. G. Warpur, together with many other interesting plants, including the lovely red-lipped Cymbidium rhodochilum, which flowered once at Kew and nowhere else. This is a plant worth sending specially to Madagascar for, in view of what is being done by breeders with the genus Cymbidium. Cynorchis purpurascens has a tuberous rootstock, and the leaves are annual. The flowers, which are produced in winter and last a month or more, are about 1½ inches across, the large, four-lobed, crenulated lip being the most striking feature, the conspicuous white disc set in the middle of the spreading rose-purple lobes and backed by paler-coloured sepals being decidedly pleasing. The plant thrives in an intermediate house, and the fact that it has now flourished at Kew for 16 years shows that it is not difficult to cultivate. It flowered there as usual this winter. C. Kewensis, a hybrid between C. purpurascens and C. Lowiana, raised at Kew some years ago, has also flowered at Kew lately. W. W.

ORCHIDS FROM WESTONBIRT.

Mr. H. G. Alexander sends from Westonbirt Gardens, Tetbury, some finely developed blooms of specially choice Orchids.

Laelio-Cattleya Orange Blossom, a new hybrid between L.-C. Elinor (C. Schroderae × L. Coronet) and L.-C. Trimyra (C. Trianae × L.-C. Myra), is the most vivid self-coloured dark orange hybrid we have seen. Although C. Trianae enters twice into its composition and gives the hybrid large size and good shape, the yellow and reddish-orange in L. flava, L. cinnabarina, and L. harpophylla in its lineage excludes all cyanic tints.

Laelio-Cattleya Aurede (C. Iris × L.-C. luminosa), taken from a spike of nine flowers, is a bright copper-red variety with a ruby-coloured front to the lip, which has a pink base with gold veining.

L.-C. Ilma, between L.-C. Myra (C. Trianae × L. flava) and L.-C. Tigris (L.-C. Dominiana × L. Cowanii), all the parents of which were raised at Westonbirt, is bright buttercup-yellow, with a dark maroon lip much undulated at the edge and having a yellow base.

Cattleya Enid alba is represented by a large and perfectly formed pure white flower, the ample lip of which is veined and tinged with violet colour and the disc pale yellow.

Cattleya Snowflake, raised between C. Düsseldorfei Undine (intermedia alba × Mossiae Wageneri) and C. labiata alba, is a grand flower, and the largest of the Düsseldorfei hybrids, the petals expanding to nearly seven and a half inches. The whole flower is of fine substance, pure white, with a slight sulphur-yellow shade in the centre of the lip.

Odontoglossum eximium Copper Queen is a very large flower of model shape, with a new tint of colour. The sepals and petals, which are nearly equal in width, bear one large and several smaller blotches of a bright copper-red colour, which show through to the backs of the segments, the margins and tips being white tinged with purple from the colour on the reverse side.

HYBRIDS FROM SLOUGH.

Messrs. Flory and Black, Slough, send the first flowers of the following three new hybrids:—

Sophro-Laelio-Cattleya Margrand (Marathon × S. grandiflora), a pretty and neatly formed flower with strong features of S. grandiflora, which has been twice used in its production. The sepals and petals are copper-yellow, with darker veining; the lip is bright yellow striped and tinged with red.

Sophro-Laelio-Cattleya Phryne (L.-C. Phryne × S.-L. Gratrixiae) has clear yellow flowers with rose-coloured markings on the front of the lip, a peculiarity being the Cowslip odour derived from Laelia xanthina in the old Veitchian hybrid L.-C. Phryne.

Brasso-Laelia Jasper (B.-L. Jessopii × Laelia harpophylla) scarcely attains the merit expected in a Brassavola hybrid in point of size, its form, and elongated, recurved lip, being dominated by L. harpophylla. The lanceolate sepals and petals are bright chrome-yellow.

PLANT NOTES.

SALVIA DICHROA

SALVIA DICHROA (fig. 56) is one of the most beautiful of outdoor Salvias, but it is somewhat tender, and must be grown in a sheltered position. In the Cambridge Botanic Garden it has been very beautiful on a border facing east, against the low wall of one of the plant houses. The species is not common in cultivation, but is not new, having been introduced by Mr. George Maw, of Crocus fame, in May, 1871. The plant flowered in his garden at Broseley, in Shropshire, in August of the following year, and was figured in the *Botanical Magazine*, tab. 5964. The species is allied to S. bicolor, which is bright blue in colour, while S. dichroa, also largely blue, has a white central lobe to the lower lip. In *Index Kewensis* S. dichroa is referred to as S. bicolor, but there are considerable points of difference. The radical and lower leaves of S. bicolor are deeply cordate, sinuate-toothed, and much cut, with spreading teeth and lobes, while those of S. dichroa are oblong-acute at the base, irregularly cut into large obtuse lobules that point to the apex of the leaf. In S. bicolor the hairs of the stem are spreading, whilst those of S. dichroa are reverted.

The plant grows from 2 to 3 feet high, and the leaves are usually from 6 to 8 inches long. The corolla is 1½ inch long, bright blue in colour, the lower lip of the same "tint" as the upper, and three-lobed; the lateral lobes are rather oblong in shape and rounded, the central white lobe being orbicular, concave, and pendulous.

The plant was collected by Mr. Maw at the base of the Greater Atlas, south of the city of Morocco, at about 2,000 feet below Tasmeroot. The cultivation of this plant is not difficult, and it may be increased by division in the same way as most herbaceous Salvias, also from seed.—*E. Irwin Lynch.*

THE ROSARY.

USEFUL ROSES

THE points of a good Rose so ably laid down by *White Rose* on p. 64 deserve more than a passing notice. His first and last points deserve most attention from raisers of new Roses, but all the eight qualities he refers to are to be desired in Roses of the future.

There are varieties that I consider conform to the standard of form and colour to be looked for in the ideal Rose. These are Catherine Mermet, Maréchal Niel, Hugh Dickson, and Frau Karl Druschki, in their order of merit. I am well aware that only in very warm, sheltered gardens are the two first named a success. Papa Gontier is the very best Rose for dwelling-room decoration. The blooms may be cut with long stems, whilst the colour and length of petal are not equalled in any other Rose. I have had the best success with this variety on limestone, and the plants grow vigorously for years if not pruned too hard. Papa Gontier, The Bride, from plants under glass, and Hugh Dickson grown in the open, with American Pillar grown on poles, are four of the most effective Roses for indoor room decoration.

Kaiserin Augusta Victoria is fine for the dinner table. The beautiful medium-sized blooms and erect stems are qualities in its favour. A pink and red variety of the same habit but more robust would be an acquisition.

Lady Roberts makes a fine buttonhole Rose when it develops that lovely bronze tint seen in some of the blooms, but the colour varies with soil and season. Many Roses of the H.T. section are useful as cut flowers, and most of them as garden Roses for summer and autumn.

Mr. Mawley was a wise man (p. 92) not to name 12 Roses for any garden outside his district. Here is my list:—1, Caroline Testout; 2, Frau Karl Druschki; 3, Hugh Dickson; 4, Mme. Abel Chatenay; 5, Pharisaer; 6, Captain Hayward; 7, Mrs. John Laing; 8, Antoine Rivoire; 9, Mrs. Foley Hobbs; 10, Juliet; 11, Duchess of Wellington; 12, General McArthur. 13, Anna Olivier; 14, Lady Roberts.

Certain varieties are best worked on a free-growing odd variety of the Seven Sisters type of Rambler. For example, Gloire de Dijon, on the Seven Sisters type of stock, is deeper in colour and the blooms have more substance.

Some of the newer Roses have fewer petals than those of 30 years ago, which is a distinct gain. Captain Christy and Climbing La France are charming flowers, but having too many petals the blooms do not open in the absence of plenty of sunshine and warmth.

Some Roses are best grown on what may be termed the extension system, that is, tying them to stakes from 3 to 5 feet high. Many Roses are ruined by being cut back too severely. The first year I train the shoots to one stake; then, as the plants get larger I use two or three stakes, and by this means obtain more flowers for cutting and the bushes live longer. I consider this method better than standards, "Bouquets on broomsticks," as Jean Sisley used to call them. Marie van Houtte, Mrs. J. Laing, Hugh Dickson, Mme. Lambard, Anna Olivier, and many others are suitable for this treatment.—*Rosa Rubra.*

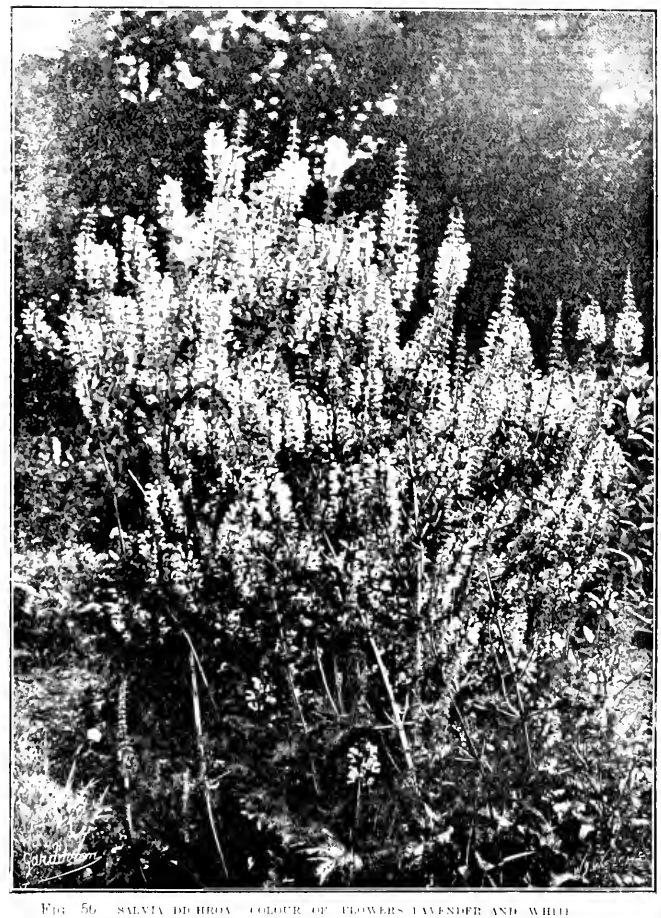

FIG. 56.—SALVIA DICHROA: COLOUR OF FLOWERS LAVENDER AND WHITE.

FRENCH NOTES.

COLUMNEA HYBRIDS

IN supplement to Mr. Lynch's interesting notes (February 16, 1918, p. 64), mention may be made of two hybrid Columneas raised in France, both with *C. magnifica* as one parent.

The first, *C. Lemoinei*, was raised at Nancy from a cross with *C. glabra*, and was put into commerce by Lemoine in 1914. The other, *C. Vedrariensis*, was obtained in 1915 at Verrières by M. A. Gentil, Andrieux and Co., and resulted from a cross between *C. Schiedeana* (♂) and *C. magnifica* (♀). As an ornamental plant the hybrid is superior to either parent. It has the habit of Schiedeana and also the floral striation and form. From the other parent it derives bright colour and size of flowers, and also its villous habit. In vigour, the dimensions of its branches and foliage, time of flowering, the colouration of the undersides of the leaves and that of the veins, the hybrid is intermediate between the two parents. The reciprocal cross with *magnifica* as the female parent resulted in similar but less vigorous plants, a fact which is not infrequent, and indicating that a hybrid takes after the female plant in respect to vigour.

Columnea Oerstediana, discovered in Panama by Warscewicz in or about 1850, was not introduced into cultivation by Lemoine until 1906, the species having been rediscovered in that

year at Costa Rica by C. Werckle. It is described in Messrs. Lemoine and Sons' current catalogue as a fine subject for growing in baskets, with long, pendent shoots bearing scarlet flowers.

A dozen species of Columnea have been described in *Bot. Mag.*, the prettiest being undoubtedly C. gloriosa Sprague (*Bot. Mag.*, t. 8,378). This species was introduced to Kew in 1909 from Costa Rica.

Columnea erythrophoea Decaisne, which was figured in *Revue Horticole*, 1867, p. 172, resembles, according to the plate, and except that its flowers are not striped, the hybrid C. Vedrariensis. *A. M.*

A WAY WITH BADLY GERMINATING SEEDS.

IN a paper dealing primarily with certain phenomena of mutation in Oenothera biennis, de Vries has recorded some interesting observations on the germination of seeds in this genus.*

The small seeds of the Evening Primroses are notorious for a high proportion of failures to germinate. In some of the forms, such as Oenothera Lamarckiana, this sterility has been shown to be due in part to the fact that about one-half of the embryos are so constituted hereditarily that further growth is not possible. Their make up at fertilisation is such that they are doomed to perish early. This, however, accounts for only 50 per cent. of germination failures, where as the actual failures frequently reach 80 per cent. or even higher. Again, among those that are successful germination is often very irregular. Some of the seedlings appear within a few days of sowing, others will take weeks or even months, while some of the seed may remain dormant for years. At first it seemed possible that this might be due to the hardness of the seed-coat, and de Vries had some tests made with one of the filing machines used at Svalöf for small, hard-coated seeds. The results were negative, owing apparently to the fact that the hard layer of the seed-coat in the Evening Primrose is not the external tissue, but that of the inner integument. The softer outer coat prevented the filing of the harder portion inside. Another possibility then presented itself to de Vries. Might it not be that the exceedingly small slits in the seed coat through which moisture is normally imbibed from the soil became full of air and penetrable only with great difficulty by water? To test this supposition de Vries thoroughly soaked his seeds, placing them in small tubes of water and keeping them over night at a temperature of 30° C. The tubes were then placed in an apparatus in which they could be subjected to a pressure of 6·8 atmospheres at room temperature for 1·3 days, the object being to force the moisture through the minute slits of the seed-coat. The result was eminently satisfactory, as may be judged from the following experiment with Oenothera Lamarckiana, in which over 3,000 seeds were used. It was found that 15 per cent. of these germinated by ordinary methods in the first two days, and a further 3 per cent. in the two following days. The refractory seeds were then placed for three days in water under a pressure of 8 atmospheres. After this treatment a further 23 per cent. of seeds germinated. The remainder were then carefully examined and their seed-coats broken with a needle. Only 5 per cent. of them contained embryos, and of these many were in a decaying condition. The result of the treatment was that over double the number of seeds were induced to germinate, the sum total being not far short of the 50 per cent. which recent work has indicated as the limit of germinable seeds in this type of Oenothera. Though it is hardly likely that the process will be applied on a commercial scale to the seed of the Evening Primrose, it clearly suggests research on interesting, and perhaps profitable lines, with seeds of greater economic value.

* *The Botanical Gazette*, Vol. LIX., No. 3, March, 1915.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

FRAME CUCUMBERS.—Make a sowing of Cucumber seed to obtain plants for growing in pits or box frames. Prepare the manure and fallen leaves for making up the hot-beds, by turning and mixing the materials several times. Make the hot-bed 15 inches or 2 feet wider than the frame to permit of placing fresh fermenting material around the frame later when the warmth of the bed is declining. Place the frame on the bed, but do not put the soil in the former for a few days or until the temperature of the hot-bed is on the decline. Place a compost of turfy loam and leaf-mould in equal parts in mounds or ridges in the centre of each light, and add fresh soil to the roots as it becomes necessary. Set the plants out when they have made two rough leaves, choosing a warm day for the work. Syringe the plants lightly and shade them for a few days until the roots are established.

VEGETABLE MARROW.—Make another sowing of Marrow seed in 4-inch pots to obtain plants for setting in heated pits or frames. Abundance of air must be given on all favourable occasions, and the frames covered at night when there is frost. With careful attention the plants will furnish Marrows several weeks in advance of those in the open. The lights should be removed when the weather is warmer, and the plants will continue to bear throughout the summer.

SPRING CROPS. Use the hoe freely whenever the ground is dry enough for stirring. Dust the surface with soot or lime where slugs are troublesome. Cabbage and Winter Spinach especially will grow more freely when the soil is kept clean and stirred frequently.

LETTUCE. Spring sown Lettuce plants of early Cabbage varieties are making rapid progress in heated pits and frames. Ventilate the frames freely on mild days, and dust soot and lime between the plants to keep slugs away. Transplant seedlings raised from a successional sowing to maintain a regular supply of heads, and sow more seed of Cos and Cabbage varieties in boxes to obtain plants for growing on warm borders later.

PARSLEY.—Where the leaves of Parsley growing in frames have been picked rather closely stir the surface soil with a small hoe and remove all dead and decaying leaves to favour the development of fresh foliage. Sow seeds of Parsley in boxes to obtain plants in readiness for planting out later. Such plants will be valuable where Parsley out of doors has been injured by the winter or where the supply is likely to be short from any other cause.

PARSNIPS. Parsnips still in the ground are beginning to grow, and should be lifted, placed in a heap under a north wall and covered with fine soil. Manure the ground freely and dig it in readiness for future crops.

COLD FRAMES. Remove the lights daily on all favourable occasions from cold frames in which such seedlings as Cauliflowers and Winter Lettuces are growing. In this way the plants will get hardened and be ready for planting at the beginning of next month. The plants may be protected on cold nights by covering them with mats; the lights can then be used for forwarding more tender crops.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

NEWLY PLANTED TREES. All planting of fruit trees should by this date be completed, even in late districts. Late-planted trees should be pruned fairly hard. It will be advisable to mulch the trees at once, and the roots should be well watered. Afterwards, if the weather be dry, the trees should be syringed on a few occasions, but when they commence to grow freely less attention in watering and syringing will be needed. See that the soil is made firm before a mulch is applied. Trees that were planted last autumn and this spring should receive attention; not much pruning will be needed, but in some instances it is essential to regulate the growth. Training to a proper shape is an important detail in the management of fruit trees at all times, but it is most necessary in the case of young trees. A wall of carefully trained trees does not fail to create an impression upon an observant mind as to the foresight and patience that have been bestowed upon the plants.

TRAINING OF YOUNG PYRAMID TREES.—Time should, if possible, be found to give some attention to the training of young pyramid trees. This type of tree should have a well-developed stem with lateral branches radiating from it of an equal vigour. Sometimes a branch becomes too large and spoils the balance of the tree. To obviate this depress all the growths from the outset, as by so doing excess of vigour will be prevented. A simply way to do this is to take old garden broom-handles, cut each one in two, and drive them as stakes firmly in the ground. The shoots may be secured to the stakes in a pendent manner. Five or six such stakes should suffice for each tree, and to this number the shoots may be tied down. In five or six years the lower branches will become quite set, and to these afterwards those of younger growth may be secured without any further need of the stakes. For tying use medium sized tarred string.

SPRAYING.—It is almost past the time for applying winter washes to fruit trees, for their use is not advisable when the flower-buds of Apples, Pears and Plums are swelling. If the Plum trees have been attacked with Plum aphis the pest should be destroyed directly it is detected, but specifics must not be used during the flowering period. It will be advisable to be prepared for an attack of caterpillars later. In many gardens last season caterpillars wrought much damage before it was possible to check them. It will be well to take the advice just issued by the Food Production Department and be prepared in time to combat this most harmful garden pest. Some prefer to use arsenate of lead, others nicotine and soft soap. Personally I am disposed to favour the latter specific. Lime-sulphur spray is now coming more into general use. It is a most efficacious remedy for many fungous diseases and insect pests. It is recommended for the destruction of big-bud in Black Currants, but I have not used it for this purpose.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

FORCED SHRUBS. When shrubs that have been forced have finished flowering they should be pruned, repotted, or receive any other attention necessary. The seed-pods on Rhododendron indicum (Indian Azaleas) should be picked off, and should there be evidence of red spider on the foliage lay the plants on their sides and give them a vigorous syringing with an insecticide. Afterwards place them in a moist, warm atmosphere to make fresh growth, a vinery or Peach-house which has just been started being suitable. In summer the pots may be plunged in ashes in a sunny situation out-of-doors. Ghent Azaleas may be repotted if necessary and grown on for a few weeks in a house having a warm, moist atmosphere. At a later stage they should be plunged in ashes out-of-doors until they are again required for forcing. It is sometimes necessary to thin the growths of Azaleas, or the shoots may grow too weak to flower. Prune plants of Prunus triloba hard and place them indoors for a week or two, to start them into growth. Only sufficient shoots should be retained to form a good head. The roots may either be repotted or top-dressed as their requirements demand. They must be placed out-of-doors for the summer to ripen the flowering wood. Pyrus floribunda may be repotted or planted out in the open. Lilacs should be pruned severely and planted out in well-prepared ground. Deutzia gracilis, after being forced hard, needs a year in the open ground

to make suitable growth for forcing a second time; this will necessitate having two sets of plants in order to have good specimens for forcing every year.

FERNS.—The repotting of Ferns should be done now, but it may be remarked that Ferns will grow in the same receptacle for two or three years without disturbing the roots, provided the drainage in the pots is efficient. Worms are usually the cause of trouble in this respect, but they are easily got rid of by watering occasionally with lime-water. Cut off all old leaves and place the plants in a warm moist house to make new fronds.

HELIOTROPS.—Cuttings of Heliotrope may be inserted now to obtain plants for flowering in autumn. Insert the shoots in pans filled with sandy soil and root them in a propagating case. Standard Heliotropes are very effective for grouping, and will last for a number of years. For this purpose select some of the strongest of the young plants and grow them on in a moderately warm house. Keep all side growths removed till the plants have attained the desired height. Attention must then be given to forming the head.

PLUMBAGO ROSEA.—Old plants of this Plumbago may be repotted now. Shake out the roots and repot them in a compost of fibrous loam, peat, leaf soil, wood ash, and sand. A few cuttings may be rooted annually to replace plants that are worn out. This Leadwort needs plenty of warmth and moisture during its season of active growth, and it will grow well in a light position in the plant stove. Stop the young plants once or twice during the growing season to obtain bushy specimens.

BROWALLIA SPECIOSA MAJOR.—Seeds of this useful plant may be sown now in pans and germinated in moderate warmth. When large enough for transferring, shift the seedlings singly into 3-inch pots and again later into 5-inch pots. Pinch the growths of the plants to obtain bushy specimens. Another sowing may be made in a few weeks to obtain plants for successional flowering. The flowers are useful all through the summer and autumn.

FRUITS UNDER GLASS.

By W. J. GRAY, Gardener to Mrs. DEWHURST, Keele Hall, Newcastle, Staffordshire.

VINERIES.—Gros Colman, Lady Downe's, Black Alicante, Mrs. Pince and similar varieties of Grapes in late houses are swelling their buds much earlier than usual this season. The late vinery should therefore be closed early in the day to trap plenty of sun heat, and the atmosphere should be kept moist now that the house is warmer. Very little fire heat will be necessary until the buds are breaking into growth; still, it is advisable to warm the pipes on dull days and cold nights by opening the valves a little. If the borders appear to be dry, water them freely with tepid water, as at this date there is less danger of giving them too much than too little moisture. The house should be syringed twice daily and a moist atmosphere maintained until the vines are in flower. Black Alicante, Gros Colman and Lady Downe's require plenty of time to finish their berries; it is therefore necessary that these varieties should be started in plenty of time to give them the full benefit of the season, otherwise the berries will not ripen by the middle of September, which means extra firing to finish them, apart from destroying their keeping qualities through the winter. The same treatment as advised for late vineries will be suitable for houses containing such varieties as Foster's Seedling, Buckland Sweetwater, and Madresfield Court, which can be grown in a mixed house with excellent results. The temperature of the vinery should range from 60° at night, with a little air admitted through the top ventilators to 65° on warm, sunny days. The changeable weather at this period will make it necessary to reduce the ventilation, as the sun loses power in order to raise the temperature a few degrees in the afternoon. If syringing of the vines has been discontinued, all bare spaces should be damped twice a day. Syringing the bare spaces with weak soot-water twice or thrice weekly has a beneficial effect on the foliage. The young laterals into position gradually; pinch out strongest shoots, and allow the weaker ones to grow unchecked for a little longer where space remains unfurnished. If insect pests are not be troublesome at the present stage, steps must be taken to exterminate them directly they are detected.

LATE STRAWBERRIES.—The exceptionally mild weather has caused the latest batch of Strawberries to grow freely, and the plants should be fully exposed to the air. If the pots are plunged in ashes the roots will not require water every day, but they must not be allowed to become dry, for even late plants are becoming active in growth, and drought would cause a serious check. Mildew spreads rapidly on pot Strawberries, and, as prevention is better than cure, it is advisable to immerse the plants in a mixture of soft soap, sulphur, and water, before they are removed to the houses. Dry sulphur may be dusted between the plants in frames.

THE ORCHID HOUSES

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CALANTHES.—The deciduous Calanthes are largely used for cutting during the autumn. The plants may be grown with good success in cool greenhouses. I have frequently seen good specimens in Mr. Cowley's and Mr. Ingram's collections, which were grown in cool greenhouses. The plants require a moderately warm temperature to start into growth, but they will succeed in the majority of greenhouses. Repotting should be done [illegible] Pots are to be regarded as [illegible] not divided roots and [illegible] the previous year's [illegible] and more [illegible] must be made. The compost should consist of fibrous loam, leaf-mould, and [illegible] and be well drained, each one will accommodate three or six pseudo-bulbs of average size. If preferred, the pseudo-bulbs may be potted singly in small pots. Keep the base of the pseudo-bulbs at least half an inch below the rim of the pot, with the young shoot resting on the surface of the soil, but in no way covered. Press the compost moderately firmly around the base of the pseudo-bulbs. Recently potted plants should be grown in a temperature of 65° to 70°. Very little water will be needed for the first six weeks; an excess of moisture would cause the tips of the young growths to turn black and thereby impair the health of the plant for the rest of the season. When the new roots have grown freely in the compost and the leaves begin to unfold, the amount of water may be increased, and from thence onwards the soil must never become dry. Plenty of light is necessary short of scorching the foliage, and the plants and surroundings should be kept moist. Healthy, back pseudo-bulbs that were removed may be used for purposes of propagation. Arrange them on a layer of Sphagnum moss in a shallow receptacle, and place them in a warm, moist house, where they will quickly produce new growth.

MILTONIA.—Plants of Miltonia vexillaria or the elegant flower-spikes from the partly developed pseudo-bulbs. Guard against attack of thrips, which, if not kept in check, will attack the tender flower-buds, causing them to become deformed. The foliage should be syringed on bright days, which will not only keep down thrips, but also be beneficial to the growth of the plants. The syringing should be done sufficiently early in the day for the foliage to become dry before night arrives. The house should be carefully fumigated on frequent occasions with a vaporising compound. The above remarks apply also to such hybrids as M. Bleuana and M. Charlesworthii. M. Roezlii should be [illegible] in the shadiest part of [illegible] house, while M. vexillaria and its hybrids, as also M. Phalaenopsis, may be grown in the intermediate [illegible] and [illegible] at all times from bright sunshine.

THE FLOWER GARDEN.

By E. BURRELL, Gardener to the Earl of [illegible], Tyninghame, East Lothian.

GOLDEN YEW.—Prune Golden Yews now, in order that plenty of young, yellow shoots may be produced during the summer and autumn months. This pruning, with a pair of hedge shears is [illegible] carried out, but where either hedges or single specimens have become overgrown, this should be done more than hand work. The same [illegible] should be followed with other hardy evergreens of coloured foliage.

DAHLIAS.—Dahlias are easily propagated from cuttings, which are produced in plenty from strong shoots pushing from the crown. The old stools should be placed in a warm house, the tubers being merely covered with leaf-mould or other light material.

LAWNS.—Grass lawns should be well swept, rolled with a heavy roller if needed, and then mown, if required, twice, the first time with the knives slightly elevated, the second time set at their usual height. Portions of grass land which are cut by hand mowers, if at all rough, may be mown with the scythe once and then run over with the machine. Our hand mowers are operated by women working at short intervals, and it is imperative that the work be never allowed to become heavy for female labour. It takes [illegible] on the whole, to mow frequently, and, in consequence, is better for the appearance of the lawn, while the condition of the machines themselves is at present a matter of great consequence, repairs and new parts being increasingly difficult, and light running being one way of obviating breakdowns. Worms in grass are a nuisance, necessitating much extra labour in cleaning up their casts. They may be destroyed by lime water, which may be prepared as follows: To 1 lb. of unslaked lime add 7 lbs. of water, and when the lime is thoroughly slaked, or reduced to powder, add 5 gallons of water, and so on in proportion. Apply the lime water to the lawn by means of a rose watering pot: the worms will duly appear on the surface, to be finally swept up. If the soil is moderately moist less lime water will be required than if dry.

FORCED DAFFODILS.—Bulbs of Daffodils that have been forced are useful for planting on grass, and may be grassed at any convenient time. Strike the bulbs free from soil and arrange them in any haphazard method on the surface of the lawn, then, with a spade, make a slit wide enough to allow of the roots and bulbs to be properly buried; withdraw the spade and press the edges of the slit together, and the operation is completed. Much trouble and labour will be saved if the bulbs are planted as the flowers are cut, and I have never found that the Daffodils suffered, at least to any appreciable extent.

THE ROCKERY.—Whatever is needed in the way of replanting may now be done, such as of cuttings which have recently been rooted or plants raised from seeds sown last year. Use a little fresh compost in the sites to be planted; a stone or a few stones embedded around them will be an effective substitute for a mulch. This will be an effective time to prune Alpine Roses, varieties of Buddleia variabilis (to be cut down), Hydrangeas, Clematis of the Montana section needing restriction, Vincas (Periwinkles), and others getting out of bounds. If Muehlenbeckia complexa has been frosted it should not be hastily removed, as I have seen a very badly frozen clump make new growths after a time. The Alexandria Laurel and Parkinson's variegated Sage may also be damaged by frost, but these plants will probably break into growth again.

THE BOG GARDEN.—Stones in the bog garden occasionally need to be raised to assure a proper footing. Weeds that may have escaped detection last autumn should be eradicated. Phyllostachys or other hardy Bamboos are almost certain to have been frosted, but though the leaves may drop the canes are not always killed, and accordingly they should not be cut over until it is certain that they are killed.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENT FOR THE ENSUING WEEK.

SUNDAY, MARCH 24—
Summer Time commences.—Clocks to be put forward one hour at 2 a.m.

TUESDAY, MARCH 26—
Roy. Hort. Soc.'s Coms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 43.0.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, March 21, 10 a.m.: Bar. 30.4, temp. 48.6°. Weather—Fine.

Fruits for Acclimatisation

There are no publications more interesting to the breeder and acclimatiser of plants than the periodical descriptive lists which are issued by the U.S. Bureau of Plant Industry. That branch of the Department of Agriculture lays the whole world under contribution, and provides for the horticultural experimenter a rich supply of promising material.

In scanning the present list,* the thought comes insistently to the mind that what the United States is doing for the American horticulturist might and should be done—when the strain of war is past—by the British Empire for the horticulturists of the Empire.

Consider for a moment one group of plants only—the fruit trees and shrubs—the list under notice contains descriptions of seven Almonds from Spain, the Caucasus, and Turkestan; twelve Peaches and Nectarines from China, Turkestan, Spain, N.W. Frontier India, and Korea. (One of the Peaches enumerated, the Sutter Creek Peach, of good quality and large size, is of special interest in that it is remarkably resistant to Peach curl); 12 Apples (Malus sylvestris) from the Caucasus and Turkestan; 8 Apricots (Prunus armeniaca) from China, Manchuria, and Russian Turkestan; and also Plums and Plum hybrids and many Pears, including a large number of varieties of the Chinese Pear, Pyrus chinensis.

Of the many varieties of these several fruits not a few might be valuable in this country and in other parts of the Empire, and it should not prove either very difficult or very costly to establish a headquarters station with outlying stations in relation with it where systematic testing of new and promising varieties could be undertaken.

At the recent conference of fruit growers other and more pressing subjects naturally engaged the attention of the experts, but nevertheless this is a subject which undoubtedly should be kept in mind by all who desire to secure yet further improvement in our fruits. If steps were taken to establish a central station for the study of problems relating to the improvement of fruits, and if the existing institutions already engaged in this subject were in one way or another affiliated with the central station, the larger scheme which we have in mind, that of a Federation of similar institutions throughout the Empire, might grow out of it. Naturally, however, the essential business of the conference held at the Guildhall on February 22 last was to consider the subject of fruit-growing in this country, and to devise means whereby the fruit-growing industry may be strengthened and extended at home.

* *New Plant Introductions.* Seventh annual list, 1917-18. Bureau of Plant Industry, U.S. Dept. of Agriculture.

DESTRUCTION OF A VETERAN PALM.—The *Revue Horticole* for March contains an interesting account of the tree of Phoenix canariensis on the isle of Teneriffe, commonly called the "Palm of the Conquest" on account of its being said to have existed there prior to the conquest of the island by the Spaniards. As this event took place in 1496, the tree appears to be over five hundred years old. The tree was destroyed by a gale on January 3 last, which broke the trunk in two. The Canary Islands were formerly thickly wooded, principally with Palms and Conifers.

DRIED POTATOS IN GERMANY.—The drying of Potatos for use during the winter and early spring has, according to the *Journal de la Société Nationale d'Horticulture de France*, long been practised in Germany, as being a more economical way of keeping the tubers than in their natural state. Drying prevents loss, such as arises from "blackening," sprouting, and sweating, as well as rendering the stock less bulky, and therefore easier to dispose of in a small space. Moreover, dried Potatos are more digestible than fresh ones, the water they normally contain being a hindrance to assimilation; all farm animals prefer them dried. The practice had become so common in Germany in the last few years before the war that already in 1914 there were 433 factories engaged in the process.

WOMEN GARDENERS.—It is stated that between October and December the Swanley Horticultural College received 540 applications for women gardeners and farmers.

ALLOTMENTS.—In the week ending March 9 56 local authorities, acting on the advice of the Food Production Department, agreed to provide 9,009 new allotments, with a total acreage of 618¼. At the head of the list was Walthamstow, with 2,190 allotments and 146 acres, whilst Keighley, with 1,500 allotments and 100 acres, came next.

SODA CRYSTALS FOR POTATO SPRAYING.—The Food Production Department of the *Board of Agriculture* has arranged with the principal manufacturers of soda crystals to supply this product during the ensuing season at £4 7s. 6d. per ton net in 2 cwt. bags, delivered to any station in England, Scotland and Wales, in 5-ton lots. In large cities and other approved centres, lots of one ton and upwards will be supplied at the same price. For lots of less than one ton, orders should be placed with local dealers. The retail price of soda crystals sold from shop or store ought not to exceed the following:—56 lbs., 3s. 6d.; 14 lbs., 1s.; 7 lbs., 6d.; 1 lb., 1d. The demand for soda crystals can only be met by the manufacturers if orders are placed immediately and delivery accepted as and when facilities offer. Horticultural associations, farmers, allotment-holders and others should therefore make arrangements to combine their requirements, and to place orders at once with manufacturers or dealers for lots of one ton and upwards, and with dealers or retailers for smaller quantities. If any difficulty occurs in obtaining supplies, a communication should be sent to the Food Production Department, 72, Victoria Street, London, S.W.

THE SUPPLY OF SOFT SOAP.—The Food Production Department has arranged that a sufficient supply of soft soap shall be available this season for fruit spraying, and the principal makers have been requested to give priority to demands which are stated to be for this purpose. Agricultural merchants who are in the habit of supplying fruit and Hop growers with soft soap for spraying, are recommended to place their orders with makers at once, in order that the soap may be delivered in time. Ample allowance should be made for delays in railway transport. Merchants and growers who experience any difficulty in procuring supplies of soft soap should communicate with the Food Production Department of the Board of Agriculture, giving particulars of the makers from whom their supplies are ordered, and the quantities required.

PRIZES OFFERED FOR A NEW NAME FOR THE JERUSALEM ARTICHOKE.—A frequent observer of the confusion of the work in the garden and kitchen caused by the misuse of the words "Jerusalem Artichoke" offers prizes for the best English name sent in by May 1 for this useful esculent. The prizes will consist of the following works:—*Trees and Shrubs Hardy in the British Isles*, *The English Flower Garden and Home Grounds* (last edition), *The Vegetable Garden*, by MM. Vilmorin Andrieux (English translation). The name must be one English word descriptive in some way of the plant, absolutely distinct from the present words "Jerusalem Artichoke." The name Jerusalem Artichoke it considered a corruption of the Italian Girasole Artiocco or Sunflower Artichoke, under which name it is said to have been originally distributed from the Farnese Gardens at Rome soon after its introduction in 1617. The plant is Helianthus tuberosus, a native of Canada and the Eastern States of North America. The judges are to be Sir FRANK CRISP, Miss WILLMOTT, and the donor of the prize. Names should be sent to Mr. W. P. THOMSON, 25, Bollo Lane, Chiswick.

HIPPEASTRUM RETICULATUM.—Hippeastrum reticulatum (see fig. 57), was introduced to this country from Brazil in 1777. The plant has leaves 2 inches broad, and peduncles a foot long, producing flowers in umbels of from three to five. The blooms are dull red, distinctly reticulated with lines of a darker shade, a whitish band down the middle of each segment, forming a sort of white star. A variety called striatifolium, introduced about the same time, differs in having scarcely any reticulating lines in the flower, and it has a line of white along the mid-rib of the leaf. The variety is more common in cultivation than the type, the leaves being more attractive, whilst the flowers are quite as showy. Dean HERBERT mentions imported varieties of H. reticulatum other than striatifolium, so that the species is evidently variable in a wild state. The same authority records a number of crosses which he raised from H. reticulatum, and it is possible that some of the plants are still in cultivation. Mr. ELWES has plants of reticulatum hybrids. Although not to be compared with the large hybrids raised by Lieut.-Col. Sir GEORGE HOLFORD and Messrs. JAMES VEITCH AND SONS, they possess a beauty that appeals to some tastes. Crosses between H. reticulatum and other species have been made at Kew, but the results

were poor. At Westonbirt, hybrids have been raised between Hippeastrum and Clivia, and the late Dr E. BONAVIA crossed Hippeastrum with Sprekelia. One wonders if the plants from these crosses ever flowered! A cross that would be valuable is Hippeastrum × Amaryllis Belladonna. HERBERT stated that whilst he found the species of Hippeastrum easy to cross, having raised at Spofforth no fewer than thirty-five different hybrids from them, every attempt to obtain a mule by the pollen of any other genus had failed. Yet where one may not succeed another may; attempts made at Kew to cross Begonia socotrana with the South American tuberous species failed, but a year or two later Mr JOHN HEAL was successful in obtaining hybrids from these parents.

is not far to seek, and your correspondent refers to it in the cutting away of the basal roots of the plants. Denuding the bulb of their roots is part of the system in vogue of preparing the bulbs for shipment, whether wittingly or unwittingly performed matters not—and while directly responsible for the losses of bulbs referred to, constitutes a piece of vandalism which cannot too roundly be condemned. Basal roots to a Lily bulb are a vital necessity if the plant is to become permanent, and cutting them away for any cause whatever is fatal to success. It is prosecuted in part, I believe, so that the bulbs may be the more conveniently moulded in moist clay prior to packing, the chief object of which is to keep them plump and fresh-looking till they reach

BULB GARDEN.

HOME-GROWN BULBS OF LILIUM.

W. T. does well to direct attention to this subject (see p. 73), and the fact that so large a percentage of imported bulbs, more particularly the huge consignments that in normal times reach this country from Japan, refuse to become established in our gardens, should provoke food for thought for all Lily cultivators. Had but a tithe of those hundreds of thousands of Lily bulbs which, during the past thirty or forty years, have reached these shores become permanently established, our gardens to-day would be redolent of the fragrance of their flowers and endowed with a grace and charm still all too rare. The reason for failure

our shores. So far as it concerns the bulb, this might at least be avoided the not inconsiderable other part becoming a total loss in transit, decomposing, the rest, that is true. But better a thoroughly dried-up and somewhat shrivelled bulb, with its complement of basal roots intact, than one fresh-looking and plump at the moment of purchasing destined only to disappoint in the end, it may be to flower as the result of the production of much stem-root, or to collapse entirely as the flowering season approaches. For the shrivelled-up bulb with roots there is hope; for the other there is none. Slowly desiccating, the dried-up bulb may fail to flower in the year of planting, but supported by its roots is capable of "carrying on," of becoming permanently established. Bulbs without basal roots may flower if much stem-root is

for the Lily specialist at home to raise from seeds or scales, or both, stocks of the choicer Lilies, if not of all. Apart from these methods, bulbils—those at ground-level and below, as in L. auratum, L. speciosum, L. Henryi, and that much larger array, as in L. tigrinum and L. sulphureum, where they are produced high on the stem, being more distinctly aerial—are prolific sources of increase if they are watched. The first of those, those that come at ground-level and below, are, I believe, very much a question of circumstance, and to some extent may be increased at will. I say this advisedly, having in mind a large consignment received late from Japan years ago that had made considerable growth, 12 inches during transit. Useless for potting, the only method of planting them that occurred to me was that of excavating a bed, or throwing

out the soil to the right and left a few inches deep, and laying the growths flat upon the soil and covering them. To my surprise many flowered quite well though the greater surprise came at lifting time, when it was seen that axillary bulblets had been produced throughout the length of the buried portion of the stems, which terminated at ground level as usual. An interesting object lesson *per se*, it gave rise to the view that here, as the outcome of circumstance, was revealed a possible method of increase which, in the case of choice kinds, might be of value. In any case it is well worth the experiment. Garden Lilies of the calibre and permanent character of regale, Henryi, Hansoni, and excelsum, are, with others equally good, ever in request, and if in the above method a new string has been added to the Lily propagator's bow, there need be little fear for years to come of the supply of such good Lilies being in excess of the demand. *E. H. Jenkins.*

LILIUM BROWNII

MR. GROVE states (p. 110) that L. Brownii of gardens is quite distinct from any form sent from Japan within recent years. With this I entirely agree, and I received Lily bulbs collected in that country long before Mr. Wilson went east. The bulb of the old L. Brownii is quite distinct from any of the Chinese forms, and, in fact, from any other Lily, but in that respect this species is nearer to L. japonicum colchesterense. The early history of L. Brownii seems to be obscure, but it is generally recognised as having been named after Brown, nurseryman, of Slough, who sent it out somewhere in the thirties of the last century. In a catalogue of a prominent nursery firm for the year 1874, now in my possession, this Lily is priced at half a guinea each. Forty years ago I was engaged in an establishment where Lilies were a speciality. The bulbs of L. Brownii were obtained from Holland, and most of them were fine, plump specimens. Later, a large number of bulbs sent from Japan and sold in the auction rooms as L. Brownii proved in many cases to be colchesterense. Up to the early years of the present century the Dutch bulbs of L. Brownii left nothing to be desired, and after that my experience of them ceased. The nomenclature of the Lily known as L. japonicum colchesterense, or colchesteri of the *Kew Hand List*, is a puzzle to me. Lilium japonicum is now regarded as the correct name of the Lily so long known as L. Krameri, and is certainly widely distinct in flower, bulb, and habit from colchesterense. To emphasise this point still more, it may be pointed out that L. rubellum, which a superficial observer might well pass over as japonicum, syn. Krameri, seems to be assigned specific rank without question. During the fifty years or thereabouts that I have known L. Brownii it has never varied in the least, so that the fact of it having altered under cultivation is difficult to imagine. It is strange that so little should be known of the origin and early history of two of our most beautiful Lilies, namely, L. Brownii and L. testaceum. *W. T.*

ON INCREASED FOOD PRODUCTION.

WINTERING SEEDLING CAULIFLOWERS

THOUGH the raising of Cauliflowers in autumn and wintering the plants in cold frames or glass houses is a very old practice, it is to be recommended in preference to the raising of seed in

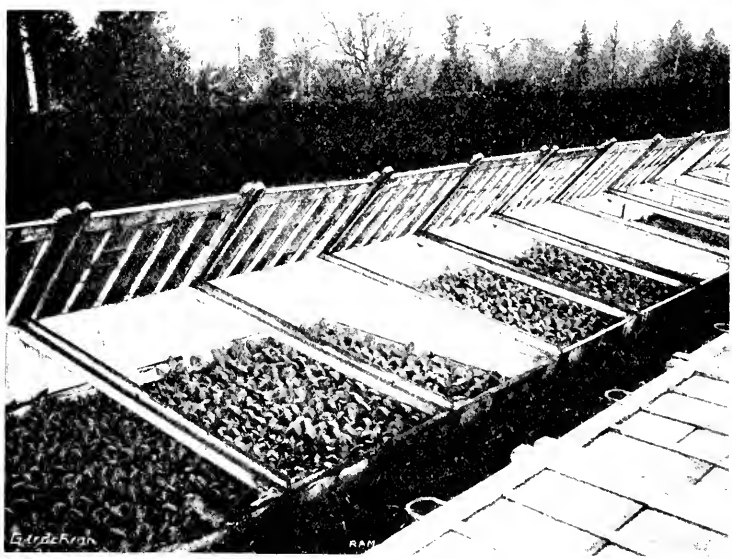

FIG. 58.—CAULIFLOWERS WINTERED IN COLD FRAMES.

early spring, as is now frequently done with some of the quick maturing varieties. The advantages are that the plants give much less trouble, produce far better heads, and, by selecting some of the strongest specimens, if suitable varieties are cultivated, they may be lifted in mid-winter and either potted in 8-inch pots singly, planted in suitable boxes, three or four in each, or in pot-like frames on mild hot beds, to produce succulent curds during April and May. Magnum Bonum and Early Forcing are amongst the best varieties for this purpose. About the end of March and during April the remainder of the plants may be planted out in various aspects in the garden for prolonging the supply. The illustration in fig. 58 shows the plants in these gardens in cold frames, the lights of which are removed on all favourable occasions. The varieties I most favour are the two above mentioned, and Walcheren and Snowdon.

The illustration in fig. 59 depicts a batch of Cauliflowers Magnum Bonum and Early Forcing potted in mid-winter, established in a cool vinery prior to introducing them to a mild heat for producing early heads. The plants are top-dressed with a rich compost and kept well supplied with manure-water. *Edwin Beckett, Aldenham House Gardens, Elstree, Hertfordshire.*

THE MARKETING OF SURPLUS PRODUCE.

I AM pleased to see that attention is drawn on p. 102 to the importance of marketing surplus produce from allotments and to the better use of vegetables than has hitherto been the case. The Food Production Department recently held a conference in London on the subject, at which I attended as a delegate from this county.

The establishment of markets in town centres has come of late under the consideration of the County Council of this county. The Agricultural Committee has recently formed a special sub-committee to formulate a scheme of markets to be supplied by the aid of motor transport from areas within twenty miles of such markets.

As a member of this committee I have taken part in deliberations on these lines, and we hope in the near future to bring the consumer and the producer closer together without the aid of the middleman, knowing so well as I do through living in the country that huge quantities of vegetables are wasted yearly solely through lack of transport and sale. By the scheme in hand we hope with our own auctioneer to sell all goods direct to the consumer, if they so wish, for their full value. Even if consumers do not purchase direct, so long as the producer is able to realise full seasonable value we feel we shall have done some good to the community. Such a scheme in full working condition will encourage growers, whether they be amateur or professional, to cultivate more extensively than in the past, and if at times prices are low owing to the laws of supply and demand, we shall be pleased if dwellers in towns obtain an advantage.

The goods are not intended to stop at vegetables and fruit. Such produce as tame rabbits, poultry and eggs will be included.

I agree, too, with your remarks on the cooking of vegetables and the employment of a greater variety of vegetables. How often are such crops as Leeks, Celeriac, Spinach, Jerusalem Artichokes, Beet, Seakale, or Tomatos found in cottage gardens, in addition to the ordinary crops? *E. Molyneux, Swanmore Park Farm, Bishop's Waltham, Hampshire.*

HOME-GROWN FOOD FOR POULTRY.

A good poultry food, which may be grown in many odd corners, will be obtained by sowing Buckwheat; the price of this seed last season was prohibitive. Linseed, which is now very expensive, may be grown in small quantities for home use, and it will form a valuable food for all kinds of stock. It is a profitable crop on newly broken land. In 1911, from plants raised from seed sown in a newly-planted orchard between rows of standard Apple trees, we obtained a good crop of seed, on soil which had been dug two spits deep, without adding manure. Sugar Beet, sown in the same orchard, and given two light dressings of agricultural salt, without any nitrate of soda or sulphate of ammonia, showed, on analysis, a sugar content of from 16-18 per cent. *J. E.*

FRUIT REGISTER.

APPLE KING OF TOMPKIN'S COUNTY.

THE valuable late dessert Apple King of Tompkin's County is of American origin. The tree is strong and free in growth, and makes a good specimen as a bush. The foliage is vigorous and leathery in texture, and is in consequence less susceptible than many sorts to attacks of fungous diseases. Spurs form evenly, but not too thickly, along the branches, and the tree seldom fails to carry a good crop. In these gardens it is one of the most consistent croppers amongst dessert Apples. The fruit is very bright, of good shape, and brilliantly coloured on the side facing the

sun, the shaded side being deep yellow. The flavour is excellent. On young trees the fruits are apt to be somewhat large for dessert purposes, but as the trees become older and of less exuberant growth they bear heavier crops of medium-sized Apples. At the present time the larger fruits are very valuable for culinary purposes. They have a pleasant flavour when cooked, and require little if any sugar to sweeten them. *T. E. Tomalin, Bessborough Gardens, Piltown, Co. Kilkenny*

NOTES ON MANURES IN MARCH.*

Ash Pit and other Residues

In view of the shortage of nitrogenous fertilisers inquiries are being made by a number of correspondents as to the possibility of utilising ash pit residues and similar waste products as fertilisers. From samples and analyses that have been submitted it appears that these residues can without great difficulty be worked up to contain about ½ per cent. of nitrogen and of potash and about 1 per cent. of phosphate. It must be admitted that the material is not of great value in spite of the noxious smell some samples possess; no fertiliser, however, ought to be judged by its smell. Ash pit residue is cheap, and can be obtained in large quantities. On heavy land it has advantages over and above its fertiliser content, for it tends to lighten the soil and make it workable. It is to be purchased for about 5s. per ton [illegible] getting. Allotment holders [illegible] find it useful.

Slaughter House Residues

In large cities some provision, though in many ways very much is made for the collection and utilisation as manure of slaughter house residues, but in smaller places the provision is very slight, and in many cases non-existent. An ordinary small township of 10,000 inhabitants, where say 600 bullocks and 1,200 sheep are slaughtered each year, should produce something like 20 tons of blood per annum and about 10 tons of other wastes of manurial value, which, if dried down and well ground, would work up into 2 tons of high grade dried blood, 1 ton of high grade meat meal and 5 tons of lower grade. These quantities are not great in themselves, but in the aggregate they are considerable. In any case, farmers or allotment holders able to secure such wastes should do so, and add them to the manure heap. A number of other wastes are obtainable from slaughter houses, and might be utilised as manure.

Sewage Sludge

Although sewage sludges are usually of no great fertilising value, they often are of some use, and when they can be obtained for nothing or at a nominal rate they may be distinctly worth collecting by allotment holders and farmers. It is a great mistake to attach any exaggerated value to them, but it is an equal mistake to ignore them altogether. Some sludges contain a good deal of lime; others a fair proportion of organic matter, although there is nearly always a large amount of water. The weakness of most of them is that the nitrogen is not easily available. Before making much use of them it is well to have analyses made.

Bonfire Ashes

Now that hedging and threshing are going on a certain amount of waste vegetable material is being burnt, and it is well to remember that the ash of this material is fairly rich in potash, of which it contains as a rule about as much as kainit. The quantity of ash available is not great, but it is valuable on light soils. In such cases a little potash goes a long way.

Catch Cropping and Green Manuring

The solution of the manure shortage is to go in for as much green manuring and catch cropping as possible. Catch cropping provides extra food for animals, and this means extra manure. Clover, Sainfoin, Vetches and Lucerne not only increase the bulk of the manure of animals to which they are fed, but they also enrich it, and their residues when ploughed into the soil add greatly to the stores of soil fertility. In districts where the second cut of Clover is apt to be poor, and where for any reason Clover seed is not readily produced, it is well to consider the advisability of ploughing up the ley directly after the first cut, and giving a bastard fallow in preparation for the succeeding corn crop. This method is practised with considerable success in certain farms in Hertfordshire.

Manuring for Potatos

In a trial made at Home, East Suffolk, a plot dressed with farmyard manure only gave a yield of 11 tons per acre, while one receiving dung and artificials, 2 cwt. sulphate of ammonia and 3 cwt. bone superphosphate per acre, gave the extraordinary crop of 26 tons per acre—one of the heaviest recorded in field trials. A third plot received in addition 4 cwt. of salt. But in this case the yield was depressed, being 14 tons 11 cwt. in place of 16 tons 6 cwt.; further, the tops showed that the salt had caused injury. The Cockle Park experiments have indicated that in the North of England a suitable dressing for Potatos is 12 tons of dung, 3 to 4 cwt. high grade basic slag, and 1½ cwt. sulphate of ammonia per acre; the dung is spread in the split drill, before planting, and the slag and sulphate of ammonia carefully distributed on the top of the dung before closing the drills.

* *Journal of the Board of Agriculture*, Vol. XXIV, No 11, February, 1918.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

THE ORGANISATION OF ALLOTMENT HOLDERS. Allotment holders are being urged on all sides to form themselves into societies, or associations, for the joint purchase of their requirements, the sale of their surplus produce, and the co-operative renting of land and owning of implements. The Agricultural Organisation Society has formed an Allotments and Small Holdings Department under the direction of a committee of which I am chairman. The one [illegible] of this Department is to [illegible] present [illegible] to organise themselves [illegible] any body of holders of allotments or small holdings which needs advice or [illegible] starting a society, or information as to [illegible] manage one for the benefit of its [illegible] can readily obtain such advice and [illegible] by writing to the head office of the Agricultural Organisation Society, Queen Anne's [illegible] Bell Street, London, S.W. 1, or [illegible] county branches. A useful booklet [illegible] issued by the Agricultural Organisation [illegible] containing how to form and work [illegible] and containing specimen [illegible] form of account book, model by-laws [illegible] useful hints in the management [illegible]. A set of leaflets dealing with the advantages [illegible] co-operative land renting and legislation [illegible] description of the work of Societies, can be obtained on application. Model rules for societies [illegible] to those desiring to register under the Industrial and Provident Societies Act and to the model rules to be [illegible] are also to be obtained on application. The Allotments Department of the Society has prepared a leaflet giving full particulars as to how a co-operative piggeries scheme can be worked successfully. The Agricultural Organisation Society, being the officially recognised body for the furtherance of co-operative methods in food production, is in close touch with all the Government Departments concerned, and its services are at the disposal of allotment holders free of charge. At the present moment some 400 allotment societies, with a membership of over 60,000, are in affiliation with the Society. It is difficult to over-estimate the value of this co-operation in food production; it is at once a real help to the individual members and a source of strength to the country as a whole. *F. D. Acland (formerly Parliamentary Secretary to the Board of Agriculture).*

UNDESIRABLE APPLES.—Mr E. Molyneux is doubtless right in asserting that lists of Apples could be profitably curtailed, but one would like to know where to begin. There are large numbers of Apples in cultivation, I suppose something like 3,000 varieties, and it must be admitted that considerable confusion exists as to the nomenclature of many old varieties. Certain varieties are peculiar to certain districts, at least that is my experience in Scotland, and one would require to think twice before discarding free fruiting sorts of good quality in favour

of varieties which thrive elsewhere and are recommended as a consequence. Take the Tweedside fruit-growing district as an example. There an Apple known as Melrose White is largely grown, and is greatly esteemed. And yet the name seldom appears in a modern catalogue. Knowing the qualities of this variety I should hesitate to recommend any modern Apple to take its place and it has been in cultivation in the Border Districts for at least a century. Advice upon discarding Apples can only really be of local value, and this fact applies more strongly to Apples and Pears than it does to almost any other kind of fruit. Mr. Molyneux, for instance, would discard Domino. A big fruit-planting scheme is now in process of completion in East Lothian, in connection with work for disabled soldiers, and the adviser of the Scottish Board of Agriculture recommended Domino as one of the Apples that should be planted. I have no experience of the variety, however, and can say nothing about it. So far as my own experience goes I would not discard Red Astrachan. It is consistently one of our best hardy Apples, and bears in abundance every season with me in East Lothian. My only difficulty is that it is regularly attacked by those excellent connoisseurs of quality in fruit—the wasps and birds. Nor yet would I discard Gravenstein. Here it is one of the finest of all Apples, and is a great bearer. It has rich, highly sugared, sparkling juice, whilst the aroma of the fruit is superb. The true King of the Pippins I would discard, for it is not equal to Golden Winter Pearmain, a variety usually regarded as synonymous with it, yet it is by far the finer fruit of the two. There are thus two stocks in commerce of King of the Pippins, and those fortunate enough to get the true Golden Winter Pearmain have no reason for complaint. The Apple is pre-eminently a British fruit, and it is most necessary that a list of varieties and synonyms should be compiled as soon as possible. That is where the value of Wisley will come in, but only in trials so far as nomenclature is concerned. It would be absurd, for instance, to say that because Melrose White or Red Astrachan are failures at Wisley that they must necessarily be failures on Tweedside or in East Lothian. *George M Taylor.*

PRUNUS PISSARTII (see p. 112).—At Hinton Admiral, Hampshire, trees of Prunus Pissartii are a magnificent sight—there are about 50 standards, some of them from 20 to 30 feet high, planted in one large clump, with Pampas grass growing underneath. The purple leaves are just opening, and the effect is beautiful; never before have the trees been covered with such a wealth of blossom. *J. C.*

STRAWBERRIES (see p. 113).—With reference to the remarks by Mr. Hudson on British Queen Strawberries, I have not tried the method he described with a main crop variety. For the past twenty-two years I have always planted Strawberries 2 feet apart and even more in the case of the stronger-growing sorts. Plenty of space between the plants facilitates the gathering of the berries, and also permits of working the soil to keep it loose on the surface and free from weeds. I do not advocate feeding plants growing in heavy, retentive soils until the fruits are well set, as I have known an excess of stimulants to cause some varieties to produce all foliage and scarcely any fruit; in light soils feeding would be an advantage in the early stages of growth. As regards making new plantations, it has always been my practice to secure all the early runners, both for forcing and planting out, by the middle of July, and to make the new plantations about the middle of August. By this system the plants form good crowns by the end of October. I have had individual fruits weighing 2 oz. from such plants the following year. It does not make any difference whether the garden is in the north or south; August is the best month to make new plantations and the ideal month to pot the plants for forcing. I have a batch at the present moment throwing strong spikes of flower. As regards Alpine Strawberries, including Black Prince and Givon's Late Prolific, the best method is to allow the plants to run wild and make new beds every two or three years. *Wm. Fulford, Delcor House Gardens, Aldenham.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 12.—*Present:* Mr. E. A. Bowles (in the chair), Sir Everard im Thurn, Sir David Prain, Messrs. E. J. Allard, W. Bales, W. C. Worsdell and F. J. Chittenden (hon. sec.).

Curious Fruit from Palestine.—Mr. Worsdell said he had ascertained at Kew that the fruit which Mr. Bowles showed at a previous meeting was that of a species of Astralagus, near to A. macrocarpus. It was peculiar in the rattling noise made by the ripe capsules.

Mahonia with partially bipinnate leaf.—Mr. Bowles showed a leaf of Mahonia Aquifolium from his garden in which one of the leaflets had developed in a pinnately compound form with three leaflets.

An early-flowering Wood Anemone.—He also showed an early-flowering form of Anemone nemorosa, possibly the variety quinquefolia, which always opens its flowers in February.

Potato tubers diseased.—Potato tubers showing black discolorations in the flesh, from which a somewhat viscous black fluid was exuding, came from Cambridge and Sunderland. This black decay is probably the result of an attack by a bacterium belonging to the Bacillus melanogenes group, and possibly produces the disease called "black leg," which was somewhat prevalent last year.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 7.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. C. Cowan, J. Cypher, A. G. Ellwood, J. Evans, P. Foster, A. Hanmer, J. Howes, A. J. Keeling, D. McLeod, J. McNab, W. Shackleton, H. Thorp, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cattleya Hercules (*Empress Frederick* × *armainvilliersensis*); *C. Monarch Colossus* (*Trianae Grand Monarch* × *Empress Frederick*), and *Sophro-Cattleya Thwaitesiae Flammea* (*S. grandiflora* × *C. Mendelii*), from P. SMITH, Esq.

Cattleya Freda Sander (*Mossiae Wagneri* × *Mrs. Myra Peeters*), and *Dendrobium Cybele album*, from S. GRATRIX, Esq.

Odontoglossum Gladys Conyngham (*cirrhosum* × *crispo Harryanum*), from Dr. CRAVEN MOORE.

Odontioda Hypatia Bedhott (*Odm. ardentissimum* × *Odo. Diana*), from Capt. HORRIDGE.

AWARDS OF MERIT.

Odontioda Mirum General Brussiloff and *O. J. B. Lakin*, from J. J. BOLTON, Esq.

Brasso-Cattleya Enid roseum (*C. Enid* × *L.-C. Leemanii*), and *Cypripedium Valentine* (*Archimedes* × *Thompsonii magnificum*), from ENGRS. of the late J. LEEMAN, Esq.

Odontoglossum crispum Nirvana, from Dr. CRAVEN MOORE.

Cattleya Lady Rowena Goldcrest (*C. Suzanne Hye de Crom* × *Warneri alba*), from S. GRATRIX, Esq.

Odontoglossum Ardentillus, from WM. PICKUP, Esq.

Cymbidium Alexanderi aurantiacum, from Mr. J. EVANS.

CULTURAL CERTIFICATE.

To Mr. J. LAW, for a plant of Dendrobium nobile nobilius, bearing 160 flowers.

SCOTTISH HORTICULTURAL.

MARCH 5.—The monthly meeting of this Association was held at 5, St. Andrew Square, Edinburgh, on this date. Mr. David Storrie, Carse of Gowrie Nurseries, Glencarse, read a paper entitled "Domestic Hardy Fruit Culture: Yesterday, To-day, and To-morrow." He spoke for Scotland only. He pointed out that over 100 years ago a lively interest was taken in fruit-growing by leading Scottish gardeners, and that many of their methods of treatment are served up to-day by writers on the subject. But, after all the lectures, writings and text-books ably dealing with both theory and practice, the position of domestic fruit gardens to-day was wretched. Bad soil was the exception, four out of every five seasons were fairly favourable, and it was only want of intelligent management which was the cause of this. Choice of varieties to suit the different localities was of the utmost importance, although in lists of selections by pomologists superior varieties were often omitted altogether. It took the grand Scottish dessert Apple James Grieve thirty years to find popularity, whilst the old culinary variety New Northern Greening, one of the hardiest and most reliable sorts, was as yet comparatively unknown. Dealing with "free" stocks, he said that so long as these were raised from seed there would be, even on the same soil, variations in the same kind of Apple, and that there should be selection of these from the seedlings and perpetuation of them afterwards by cuttings or layers, thus giving the free stock the same reliability as the broad-leaved Paradise had. For Plums five or six different stocks were used, and as to which was best for any particular variety about as little was known to nurserymen as to gardeners. Pears should always be worked on the Quince stock. He dealt with the questions of pruning, manuring, lifting and replanting, and surface cultivation of the soil, and he put in a strong plea for the institution of experimental gardens, as training centres for young gardeners and others, in every county in Scotland. He also thought that Apples and small fruits could be as easily grown on allotments as Peas, Potatos and Onions.

Mr. Storrie was awarded a silver medal for fruit trees, and cultural certificates for seedling Cyclamen and Primula malacoides compacta. Mr. D. Macdonald, Trinity Cottage Gardens, Edinburgh, received a cultural certificate for an exhibit of Camellias.

ROYAL SCOTTISH ARBORICULTURAL.

FEBRUARY 20.—The annual business meeting of this Society was held at 5, St. Andrew Square, Edinburgh, on the 20th ult. The Duke of Buccleuch was elected president, and it was stated that the membership was 1,373, an increase of 35.

A discussion took place on the recommendations contained in the Report by the Forestry Sub-Committee of the Reconstruction Committee, and the following resolution was passed unanimously, viz.: "That this meeting of the Royal Scottish Arboricultural Society welcomes the publication of the Report of the Forestry Sub-Committee of the Reconstruction Committee, and urges the Government to adopt the scheme of afforestation recommended in the Report, and to bring it into operation without delay." Sir Hugh Shaw Stewart proposed as a motion that they express the opinion that the only way in which these recommendations could be efficiently carried out was by the formation of a central forestry authority for Great Britain and Ireland, but it was pointed out that, no notice having been given, this motion could only be dealt with at a special meeting. A special meeting was therefore called for March 15, and on that date, the President being in the chair, the following motion was passed by an overwhelming majority: "That this meeting of the Royal Scottish Arboricultural Society, specially convened, hereby approves of the recommendations of the Forestry Sub-Committee of the Reconstruction Committee, and particularly of the recommendation that a Central Forestry Authority, equipped with funds and powers, be created for Great Britain and Ireland, and urges the Government to carry these recommendations into effect without delay."

Obituary.

WILLIAM B. BOYD.—The death occurred on March 6, at his residence, Faldonside, Melrose, in his 88th year, of Mr. William Black Boyd, a prominent Scottish amateur horticulturist. Mr. Boyd was particularly interested in alpine and bulbous plants, which he cultivated with great success, and especially Primulas and Saxi-

frages. It was with his assistance that the fine Saxifrages, including Boydii, Boydii alba, Cherry Trees, and Faldonside, were raised by his brother, Mr. James Boyd. He also took a keen interest in Snowdrops, Chionodoxas, Scillas and Narcissi. Mr. Boyd was an expert in Pteridology, and possessed a wide knowledge of British Ferns.

CROPS AND STOCK ON THE HOME FARM.

Rearing of Poultry.

This is not the time to encourage the hatching of chickens in large numbers, but sufficient birds should be reared to retain choice breeds and the best laying strains of the type that succeeds best in the particular district. Hens should not be kept beyond their second year, as after that period they do not lay a sufficient number of eggs to render them profitable.

At one time I kept as many as seventeen distinct kinds of fowls, and found them all useful, some for egg production, others for table chickens, whilst some provided broody hens, an important item in the poultry industry, and very necessary here, where hundreds of turkeys were formerly reared in addition to 2,000 chickens. Guinea fowls, ducks and pheasants. Those of the Wyandotte breed are the best sitters, and especially the golden type, the hens being light and gentle in manner.

The main point to observe now is strict economy of food and the production of as many chickens as will provide the necessary eggs and table fowls. Some of the most desirable breeds for eggs are White Leghorns, White Wyandottes, Rhode Island Red, Black Minorca, Buff and White Orpington, and Light Sussex, with an Indian Game cross on Buff Orpington. Light Sussex and Silver or Dark Dorking hens are useful for table chickens.

Cockerels from any of these breeds give table birds of good quality, colour, size, and straight in the breast. Those hatched at the end of March or early in April sell readily in November for stock purposes. Pullets raised at the same period for egg production are even more profitable.

A good type of incubator is, as a rule, the best method of hatching chickens, but now that oil has increased in cost the economy is not so great over that of setting the eggs under hens. If an incubator is used a room free from floor vibration is an absolute necessity; the incubator must stand level on a firm base. The thermometer in the egg drawer should register 101° for two or three days before putting in the eggs, which should be of good size, normal in shape, and perfectly fresh. It is not necessary that they should be of one sort, but all should be less than a week old. As the eggs are placed in the drawer the date should be written in pencil on one side, and on the opposite side a cross. This method of marking the eggs facilitates their being turned twice daily, to prevent the contents sticking to the shell and to cool the eggs, for, say, ten minutes. A quick way of turning the eggs is to wet the tip of the index finger and roll over the eggs until the mark underneath is uppermost. The eggs should not be turned after the eighteenth day, as this involves a risk of drowning the chicks by the liquid in the shell, but they should be cooled as recommended. The thermometer in the drawer should regularly register 103° or 104° but not more.

When hens are used for hatching it is wise to put down two birds or more at the same time, as one hen may have a poor hatch and must of necessity afterwards occupy a coop even if she has but four chickens, whereas if two or more are set at the same time a full coop of chickens is assured for each hen, which means economy of space, time spent in feeding, and general attention. When a brood of chickens has to be made up from more nests than one do not give a hen strange chickens after she has had her own several days, as she quickly resents strangers, so much so that she often kills them for "intruding," as she supposes. The hens should be taken off the nest for a quarter of an hour daily at the same time—say, 8 o'clock; if the removal is irregular the hens become fidgety and often leave the eggs by standing up in the nest, thus cooling the clutch.

Take the hen off the eggs regularly, therefore, give her food and water, and return her carefully to the eggs, closing the nest-shutter securely and keeping all quiet until the following day. Some hens do not take readily to their nest, although they are quite broody: in such a case keep the hen in the dark for a day or two by covering the nest with a bag until she settles down quietly.

Charlock.

Charlock (Brassica sinapis) is a great pest in many counties on light soils, and especially in the south. It infests such spring-sown crops as Oats, Barley and roots. The seed of Charlock can remain dormant in the ground for many years, and directly it is brought to the surface by deeper ploughing commences to germinate. Autumn-sown Wheat and Oats are not affected by the weed, as Charlock cannot withstand frost. This is one reason why winter Oats are more generally grown in some localities than in others, as the labour involved in checking the growth of the Charlock is much less than in the case of spring-sown Corn, but it is doubtful if the crop of Corn is equivalent.

The spraying of Charlock among Turnips, Vetches or Mangold, or any plant with rough leaves, is not practicable, as the solution adheres to the leaves, as in the case of Charlock, and injures the plant. Among cereal crops, however, this danger is not present. Another point in favour of spraying the cereal crops is that the root crops previously mentioned generally follow cereal crops, therefore it is reasonable to suppose that if the Charlock among the cereals is killed there will be less seed of the weed to grow when the same land is cropped with roots.

Many persons also condemn the practice of spraying their Corn crops to destroy Charlock have, I fear, done the spraying inefficiently; generally they have deferred the operation until the weed was too sturdy and hard in the stem to be killed. The spraying should be done directly the first rough leaf has formed. No harm accrues to the Corn crops by spraying, though it may turn the leaves a little brown at the tips. This discoloration quickly passes off, and I believe that the Corn is stimulated in its growth by the spray solution. For Corn land a 3 or 4 per cent. solution (30 or 40 lbs. of copper sulphate to 100 gallons of water) is a safe quantity to use, with a sprayer which distributes the solution in the form of a fine mist. Fifty gallons per acre is sufficient.

Peas for Pigs.

As the ordinary forms of cereal food cannot be obtained in quantity Peas can be used as a substitute for cereals for small pigs after the weaning period and until Kilting time arrives. It is too late to sow the ordinary field Peas, but I propose to grow garden varieties such as Senator, Yorkshire Hero, Eclipse, or any other free-bearing variety that does not grow more than 4 feet high. Such varieties as these, and especially the first named, yield large crops, if given liberal cultivation and supported with ordinary Pea sticks in good time. In deeply-ploughed, well-manured land I purpose growing several rows 200 yards long, and shall sow the seed thinly, certainly not nearer than 3 inches apart. By August such rows should yield much food for pigs in autumn which is a time when they require substantial food, having been receiving during the summer much softer green victuals. If the seed is sown in rows running north and south, and the plants carefully mulched in dry weather, a good return can be reasonably expected.

Nursery Wheat.

I have just completed the sowing of nursery Wheat on two fields of recently ploughed grass land, thinking that Wheat is of more importance to the nation than Oats or Barley. If nursery Wheat does not give so heavy a yield as some other varieties it is generally "strong" in the berry, and that is what the miller requires. The soil in one field is light in texture, overlying a chalk subsoil. The ground, in addition to having sheep fed on it, was dressed with farmyard manure at the rate of 10 tons per acre, and, if required, it will be given soluble plants of ammonia at the rate of 1 cwt. per acre. The second field is stiff soil with a thick grass turf which had been a poultry run for several years, so I am expecting good results from this land without adding manure. The Wheat will be followed by Oats or Potatos next season, when the turf should be thoroughly decayed.

Preparing for Potato Planting.

No time should be lost in getting the soil into a friable condition by cross-ploughing and by the use of the cultivator, disintegrating the hard portions, often the result of ploughing the ground when in a wet condition. Land for Potatos cannot be worked too much, especially if it was previously grass land. The more the soil is exposed to the surface the greater will be the opportunity for birds to clear off grubs, such as wireworms. The tubers, if not already set up to sprout in boxes, should be sorted in readiness for planting, rejecting very small tubers, although "seed" purchased now, having passed the Government 1½ mesh sieve, includes more small tubers than formerly. Any tubers that show the slightest sign of dry rot or other disease should be rejected; all such details as these, if carried out now, will facilitate the work of planting later.

Carrots.

Grown in light loam free from stones I know of no crop that will produce a greater yield per acre than Carrots, which are useful as food for man and cattle. Horses especially enjoy a feed of Carrots in the spring, and the roots act as medicine, making the animals' coats shine after a moderate grooming. The Belgian White variety is the most suitable sort for cattle, giving a large yield. The plants should be given more space than the Red Intermediate, which is one of the best varieties for human consumption. Other good garden Carrots are Red Surrey and Altringham.

Kohl Rabi.

In districts where a difficulty is experienced in obtaining satisfactory crops of Turnips for early feed for fattening lambs, Kohl Rabi is a good substitute, giving a great bulk of nutritious food. The Champion Short Top variety should be sown first, to be followed by Hardy Green. The cultivation is much the same as that for Turnips following a straw crop. Ten tons of farmyard manure per acre applied in the autumn before ploughing, and 3 cwt. of superphosphate when drilling in the seed early in April at the rate of 2 lbs. per acre, will give a considerable increase of crop. Kohl Rabi transplants easily, and blank spaces in the drills may be made good in this way—in fact, the plants may be set out entirely by planting from a seed bed, although this system entails more labour. Gaps in the early Turnip crop may be made good with plants of Kohl Rabi. If the roots are required for human consumption they should be pulled and stored in sand before they become too old, for the flesh is liable to become tough and tasteless as compared to the young, succulent roots.

Grass for Hay.

The time has arrived to "lay up" pastures from which Hay is to be cut this season. Before doing this any long, rough grass that would inconvenience the grass cutters later may be cropped by lean cattle from the straw yard—the animals would eat the rough herbage down bare and greatly facilitate the work of cutting the Hay. A dressing of 4 cwt. of superphosphate or 2 cwt. of sulphate of ammonia would give a fillip to the growth of the grass, previous to harrowing, which is beneficial in scattering droppings and removing moss. Afterwards firmly roll the surface, for this attention will prove of much value in facilitating cutting the grass, in addition to favouring growth, as the roots will be consolidated by pressing the loose soil on the surface. Where obtainable a compost of decayed manure, vegetable refuse, wood-ash and quick lime would make a vast improvement to the growth of the turf, producing close, sweet herbage. The lime and other materials are easily worked into the surface by harrowing and rolling during dry weather. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham.*

MARKETS.

COVENT GARDEN, *March 21st.*

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—EDS.

REMARKS.—Supplies show little change from last week. White flowers appear to be more in demand, and prices are firmer for best quality blooms, inferior lots being of somewhat irregular value. Roses are increasing in numbers, and are cheaper. Lady Hillingdon and Niphetos are on sale, the latter variety being the most in demand. The supplies of Carnations are ample and for the demand, and blooms are improving in quality. Lily-of-the-Valley and Camellias are cleaner. Large quantities of Stock, Sort of Bethlehem (Allium), White Roses, and Richardias (Arums) have been despatched to Wales this week for Palm Sunday, and larger quantities of these flowers will be required for the Easter festivities next week. A general rise in prices is therefore expected during the next few days.

— Cob, per lb.	1 9 – 1 10
Oranges, per case	100 0 – 140 0
Strawberries, forced, per lb.	8 0 – 20 0
Walnuts, kiln dried, per cwt.	100 0 – 110 0

REMARKS.—Stocks of Apples are now very much depleted. The following varieties are on offer:—Bramley's Seedling, Newton Wonder, Dumelow's Seedling, and French Russets (French). Forced Strawberries are more plentiful. Both Grapes are nearly over, several growers are finishing this week. Almeria Grapes (Spanish) continue available. Supplies of Asparagus are reaching the market from Devonshire Millisex, and the Continent. Forced Vegetable Marrows are on offer, and Cucumbers are fairly plentiful. Supplies of Mushrooms show an increase on last week. A few English Tomatos are on offer this week. Natural and forced Rhubarb is plentiful, but Seakale is somewhat scarcer than usual. Cauliflowers are fairly plentiful, and very good supplies of Dwarf Beans are on offer. *E. H. R., Covent Garden.*

GARDENING APPOINTMENTS.

Mr. Alfred J. Nightingale, to the past 11 years and 7 months Gardener to F. ALLEFEY, Esq., Bury Down, Newport, Pagnell, Buckinghamshire, and formerly at Rewlands, Northampton, and Bignor Park, Sussex, as Gardener to A. ALLISONE, Esq., The Grange, Ealls Burton, Northampton.

Mr. John Lemon, for 13½ yrs. Gardener to H. J. W. MARTIN, Esq., West Grove, Mill Hill, Middlesex, as Gardener to Lieutenant-Colonel BARROW, Farmington Lodge, Northleach, Gloucestershire.

SCHEDULES RECEIVED.

Croydon Horticultural Society's Show of Vegetables and Home Produce.—Wednesday, July 17, 1918. Secretary, Mr. L. R. Whitehead, 11, Addiscombe Court Road, Croydon.

Brighton, Hove, and Sussex Horticultural and Food Production Society. Autumn Exhibition of Vegetables, at Dyke Road Aquarium, Brighton, on October 15 & 16, 1918. Secretary, Mr. A. J. Gaston, 140, Springfield Road, Brighton.

CATALOGUES RECEIVED.

KELLY & WALKE, Ltd., 55, Strand, Strand, London.—Special Seed Catalogue.

W. E. JENNINGS, Bath Common, Walsall.—Empire Garden Cult. Notes.

H. CANNELL & SONS, Eynsford, Kent.—Fruit trees and Roses.

ANSWERS TO CORRESPONDENTS.

ALLOTMENT: *D. K. P.* Seeing that the ground has been well cultivated, enriched with a fair amount of manure, and dressed with basic slag and ground agricultural lime early in November, it should be in good condition to carry crops this season. The best method of applying the sulphate of ammonia is to dust it on the ground at the rate of 2 oz. to the square yard just before sowing or planting a crop. This fertiliser should not be buried deeply: the subsequent planting will disturb the soil just enough to cover it. The sulphate of potash should be applied at the same rate and the same time. With regard to the road-sweepings, they must not be used if they contain petrol or motor oil, or even tar. The very best material for your purpose would be wood-ash. Seeing that your ground contains so large a percentage of clay, it will inevitably be somewhat heavy for the first year or so, and it would be unwise to trench it too deeply. Gritty soil, leaf mould, wood-ash, peat, old mortar rubble, lime, and burnt clay, well forked in, would permanently improve the ground, but the best way of bringing the soil into a friable, well-pulverised condition is by throwing it up in rough clods in the autumn, and leaving it thus all the winter exposed to rains and frosts. Never fork it over when it is very wet; nor should the lumps thrown up in the winter be allowed to become baked by the sun in the spring before they are broken up. For such crops as you name stable manure is necessary, but for the Cabbages and Carrots fresh dung is not desirable, nor should leaf-mould be used for Carrots. Seeing that your soil is rather wet, the Celery may be grown on the flat ground instead of in trenches, but be careful that the roots do not suffer for want of moisture. Dusting the foliage with soot when it is damp will help to ward off attacks of the Celery Fly. The blanching can be done with brown-paper bands as recommended on p. 116. Autumn-sown Onions will do better than those raised from seed sown now, and will be less liable to be injured by the Onion Fly. Soot is an excellent manure for all vegetable crops, especially at the seedling stage. Good King Henry is Chenopodium Bonus-Henricus, a British plant; it is sometimes known as Mercury. It should be grown in a warm position in well-drained soil. Sow the seeds now and thin the seedlings to about 2 feet apart each way.

LICENCE FOR SALE OF POISONS: *W. B.* Apply to your local Urban District Council for the necessary form to fill in.

NAMES OF FRUITS: *J. L., Ireland.* 19, Blenheim Pippin; 21, Sturmer Pippin; 26, Dutch Mignonne (syn. Reinette de Caux); 31, Harvey's Wiltshire Defiance; 32, Golden Reinette; 33, Claygate Pearmain; 34, King of the Pippins.

NAMES OF PLANTS: *J. B.* 1, Arbutus Unedo; 2, Prunus Pissardii.—*E. N., Keston.* Acacia dealbata ("Silver Wattle").

SILVER LEAF IN PEACH TREE: *E. W.* Since it would appear that the tree of Prince of Wales Peach is certain to die, being so badly infested with Silver-leaf disease, your best plan will be to root it out completely and burn it, or it will infect the other trees in the house which are apparently still healthy. Be careful to remove the whole of the roots, and also the soil for a few feet around them; this soil should not be placed near any kind of stone-fruit trees, but wheeled to the vegetable quarters. Replace the soil by fresh compost, and be careful that the tree planted in place of the Prince of Wales is quite healthy. Watch the other trees in the house for symptoms of Silver-leaf, and the moment you observe the disease cut out the affected branch well below the seat of injury.

SOYA BEAN: *E. M.B.* The article on the Soya Bean by Mr. Irwin Lynch, of the Botanic Gardens, Cambridge, was published in the issue for January 26, 1918, p. 38.

PROTECTION OF GORTERIA AND NEURADA SEEDLINGS.

WHILST contrivances for the effective distribution of seeds are many and varied, there seem to be comparatively few which are adapted for this purpose and at the same time serve as a protection for the young seedling. A remarkable example, however, occurs in Gorteria, a genus of Compositae, represented by four species, natives of South Africa. All four plants are very closely related and difficult to distinguish from one another. In each flower head there are several flowers surrounded by an involucre of rigid spiny bracts, the latter being connate at the base into a more or less woody cup (see fig. 60). The heads are solitary at the end of each branchlet. They eventually break off at the apex of the peduncle, and fall bodily to the ground with the persistent flowers and ripe achenes inside. After rolling about in the wind—for they are extremely light—they probably become wholly or partially covered by sandy soil. At length one achene germinates, to the exclusion of the remainder, whilst still enclosed in the involucre of bracts, and pushes its radicle through the hole at the bottom of the head, where it was attached to the peduncle. The plumule emerges from the space between the bracts at the top of the involucre, which is held a prisoner around the hypocotyl, and it remains there during the entire life of the plant. This persistent involucre is present on every specimen preserved in the Kew Herbarium, and would appear to be an important generic character not previously noted.

No doubt this feature of Gorteria is familiar to many South African botanists, for at least one species is common on the Cape Peninsula, a favourite and convenient collecting ground for those in the neighbourhood of Cape Town. But no reference to the peculiarity has been found in any papers on such subjects. Marloth did not mention it in his presidential address to the South African Philosophical Society for 1894, which gave an interesting account of the means of distribution of seeds in the South African flora. For in all probability the light, woody, prickly involucre would at first act as a carrying agent in the dispersal of the achenes, either by being blown about by the wind or by attaching itself to animals. Marloth (l.c., p. 79) states that there are few instances in the South African flora in which the whole plant or its inflorescence is blown about by the wind. He records as examples the umbels of Brunsvigia (Amaryllidaceae) and a species of Stachys (Labiatae). To these, then, may be added Gorteria.

This remarkable method of distribution and protective germination is very probably quite unique in the family Compositae, with its upwards of 12,000 species. There are analogous features in the families Rosaceae and Leguminosae. In Neurada procumbens (Rosaceae), a native of the desert regions of North Africa and the Near East, the floral envelopes, the calyx and petals, persist and surround the hypocotyl of the seedling in exactly the same way as in Gorteria. But here, as will be readily understood, there is only one flower concerned, and not an inflorescence, as in the Compositae. It is somewhat curious that this genus has lately been found to be represented in South-West Africa, a second species having been discovered a few years ago by a German collector named Dinter, at Orumbo, in Hereroland. It was described by Dr Hans Schinz, of Zurich, as Neurada austroafricana. It is very closely allied to N. procumbens, and shows the same peculiarity in germination.

In the Leguminosae, the spirally twisted pod of several species of Medicago

FIG. 60. YOUNG PLANT OF GORTERIA PERSONATA.
Showing persistent involucre of bracts enclosing the hypocotyl (nat. size) and longitudinal section of same (enlarged).

encircles the seedling during growth in a similar way to Neurada, but it is not so strikingly persistent as in that genus and in Gorteria. In the Leguminosæ, then, we have a third type, the fruit, giving protection to the growing seedling. I have noticed this characteristic in several species from the Mediterranean region, namely, in Medicago santellata, Ait., M. elegans, Jacq., M. sphærocarpa, Moris., M. turbinata, Willd., M. globosa, Presl., M. Gerardi, W. and K., M. agrestis, Ten., M. Tenoreana, DC., M. charis, Willd., M. Echinus, DC., and M. disciformis, and perhaps in a few other species. A similar condition occurs in one or two Oriental species of Hedysarum.

As some confusion has existed in herbaria regarding the limitation and distribution of the species of Gorteria, I have added the following key, and all the available records of collectors.

KEY TO SPECIES OF GORTERIA.

Stems mostly diffuse, hispid; flower head solitary at the end of each branchlet:

- Ray-flowers very broad, broadly obovate rounded and entire at the apex, rather shorter than the involucre ... 1. G. calendulacea
- Ray flowers usually very narrow, oblong or linear, clearly notched or toothed at the apex, usually equalling or longer than the involucre, rarely shorter.
  - Inner involucral bracts at flowering time with long bristle-like points glabrous in the upper part ... 2. G. personata
  - Inner involucral bracts at flowering time with short glabrescent apices, ciliate and flat nearly to the apex ... 3. G. diffusa
- Stems usually erect, glabrous or sparingly setose; flower heads crowded, corymbose; involucral bracts slender, densely villous with long silky white hairs ... 4. G. corymbosa

1. Gorteria calendulacea, DC. Prodr. vi. 501; Drège, Zwei Pflanzengeogr. Docum. 102, 104; Harv. in Harv. and Sond. Fl. Cap. iii. 470; Bolus and Wolley-Dod, Fl. Cape Penins. 283.

Distrib.—South Africa: Cape Division; Lion Mountain, dry stony places below 1,000 ft. Oct., *Drège*.

Drège (l.c. 102) states that he also gathered a plant of this species between the Paarl Mts. and the Paarde Berg, in the Paarl Division. I have not seen this specimen. The species may now be extinct, for it has not again been collected since its discovery by Drège in 1840. It is a small diffuse plant characterised by its broad ray flowers, which are about as long as the involucral bracts.

2. Gorteria personata, Linn. Sp. Pl. 1283; Thunb. Fl. Cap. ed. Schult. 696; Less. Syn. 51; DC. Prodr. vi. 501; Harv. in Harv. and Sond. Fl. Cap. iii. 470; Bolus and Wolley-Dod, Fl. Cape Penins. 283.

ORCHID NOTES AND GLEANINGS.

NEOMOOREA IRRORATA.

At the meeting of the Royal Horticultural Society on the 12th inst., Mr. Thurgood, gardener to H. T. Pitt, Esq., Rosslyn, Stamford Hill, received a Cultural Commendation for a noble plant of the rare Neomoorea irrorata (see figs. 61, 62). Mr. Pitt's specimen was additionally interesting, inasmuch as it was a part of the original plant acquired at the dispersal of the Burford collection. The plant bore large, green pseudo-bulbs, each with a pair of broad, pleate leaves, and having two upright spikes of many pretty flowers, which are more than 2 inches across, the sepals and petals being of a peculiar red-brown with yellowish white bases. The lip, which in structure somewhat resembles Houlletia, is straw yellow spotted and barred with dark purple-brown. The species was described from the type plant at Glasnevin in *Gard. Chron.*, July 4, 1890, p. 7, as Mooreа irrorata Rolfe N. gen. and sp.

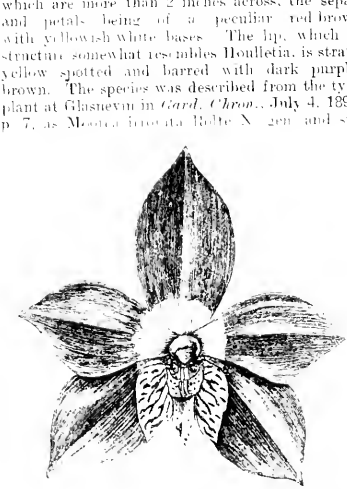

FIG. 61.—FLOWER OF NEOMOOREA IRRORATA: COLOUR BROWNISH RED. NAT. SIZE.

the fact that Mooreа had been applied many years ago to the Pampas Grass having escaped at Trenton, and this necessitated the change of name to Neomoorea. It was first shown from Glasnevin at the Royal Horticultural Society's meeting of March 22, 1892, when it was awarded a First-class Certificate. For some years the native habitat of this Orchid was unknown, but it has since been recorded from the region of the Alberto River, Province of Santander, S. America. The plant bears much resemblance to Lycaste gigantea, and grows in the same region, but botanically it is widely separated.

CYMBIDIUM RHODOCHILUM.

The statement by W. H. on p. 122 that this beautiful Madagascan species "flowered once at Kew and nowhere else" is incorrect. The plant flowered first at Kew, and subsequently in several gardens. Dr. Hodgkinson showed it at the Manchester and North of England Orchid Society's meeting, May 15, 1904, and secured a First-class Certificate for it, a similar award being given when Mr. Bradshaw, of Southgate, showed it at the Royal Horticultural Society's meeting on May 9, 1905. At the Temple Show, May, 1906, Messrs. Wm. Bull and Sons included a fine specimen in their group, the plant forming the subject of the supplementary illustration in *Gard. Chron.*, June 17, 1905. The handsome, pale greenish-yellow flowers have petals spotted with purple, whilst the lip front and sides are bright red. The species would probably be of value to raisers, and if hybrids of it could be obtained they would tend to break the monotony of the now rather overworked hybrid Cypripediums of to-day. But the plant gives another instance of lost opportunity to perpetuate rare species by home-raised seedlings, and thus ensure for gardens the continuance of what was known to be a rather difficult subject. The plants have doubtless all vanished, but if seedlings had been raised they would have been much more amenable to culture than imported specimens. I have often urged the necessity for obtaining true seedlings of rare imported species, and it is to be hoped that growers will give the matter their attention. Mr. Warpur, the collector, stated that Cymbidium rhodochilum always grows on masses of Platycerium, and some of his plants were on that Fern when distributed. The specimen in Lord Rothschild's gardens at Tring Park was growing on a mass of Fern, and, suspended in a warm house, it did well for some time. Others which were potted in the same manner as Cymbidiums quickly collapsed. *J. O'B.*

MORE SPRING FLOWERS.

The time when the scent of the Crown Imperials is wafted about the garden is always interesting, for it is a time when most plants that disappear under ground in winter are reappearing. Some might be inclined to call the scent of the Crown Imperial a smell and to dislike it, but to me it is never displeasing. Where the scent comes from and how it is dispersed in puffs or whiffs many yards across the garden is always a mystery, and surely there are not many plants which give off so distinct a scent at such an early stage in their annual development. For those who do dislike the scent there is a form or species, Fritillaria modora, but it is apparently a rare plant, and I only remember to have seen it once doing really well, and that was in a sheltered corner of the late Sir Michael Foster's garden on the hillside at Shelford. It is rare probably because it flowers early in April, and therefore often suffers badly from rough weather by reason of its early development.

This year the beautiful dark Anemone, with its drooping heads, that I take to be montana, has come into flower several days in advance of Pulsatilla. This is not always the case, and yet the two groups of plants are growing within a few feet of one another and have been undisturbed. It seems as though the night frosts, which have been frequent of late, have checked Pulsatilla, but have had little effect on montana.

Tulipa Kaufmanniana is now at its best, and its best is very good indeed. It is curious how each individual flower seems to grow from day to day. At first the buds seem very small, but after a few days they develop into normal or even very large flowers. The form in which the flowers are wholly yellow, seems to open a few days after the white and yellow type, and also after the rare scarlet form. Possibly the last is really a different but closely allied species. It breeds true from seed when self-fertilised, or at any rate the first of my seedlings that have flowered are wholly scarlet, and it is also capable of producing two flowers on the stem, though I have never known this to happen in the case of the type. Moreover, the flowers never seem to open out flat in the sun, as do the white and yellow forms, which seem to come indiscriminately from seed of either.

A very fine early Tulip has resulted from a cross between Tulipa Greigii aurea and T. Kaufmanniana. I owe my original bulb of this plant to the generosity of M. Denis, of Balaruc-les-Bains, but, if my memory is correct, the cross was made either at Haarlem or at Oberlahnstein. It in-

creases slowly by offsets, and flowers with Kaufmanniana, and therefore well in advance of Greigii. The colour is a clear, soft yellow, with a broad band of scarlet down the centre of the back of the outer petals, and the shape is rather that of Greigii, the most shapely of all Tulips.

Two early Tulips are also in flower under the names of Polychroma and Pulchella, though it is not certain that they have much right to these names. Each Tulip species seems to have been described on a totally distinct plan by someone who was blissfully ignorant of the allied species with which it might be compared and confused. What I have as Polychroma has flowers of a pale pink of a curious globular form, while Pulchella is a deep red with a blue base.

As usual, Iris orchioides alba was the first of the tall Turkestan Juno Irises to come into flower, closely followed by a pale lemon coloured seedling of I. bucharica. I. orchioides alba increases very fast here in the shelter of a cold frame, which always remains open. It is distinctly smaller than the type, but a valuable addition to the group. *W. R. Dykes, Charterhouse, Godalming.*

MANURING EXPERIMENTS ON FRUIT.

THE Sixteenth Report of the Woburn Experimental Fruit Farm, by the Duke of Bedford and Mr. Spencer U. Pickering (Amalgamated Press, London), summarises the results of manuring experiments on Apple trees from 1895 to 1915, previously dealt with for the first eight years in the Fourth Report. The lack of fruit in 1916, it is explained, rendered that year a blank in relation to the experiments. So far as the original trials on the Ridgmont Farm are concerned, the almost entirely negative results at least in the manuring of Apple trees, shown in the Fourth Report, are stated to have been confirmed in the years that have elapsed since the date of that report. Wood formation, sizes and weights of trees, sizes of leaves, and weights of fruit are declared to have been entirely or almost entirely unaffected by the annual application of artificial manures or dung. It is a pity, however, that, with the exception of one account of wood growth, this is not demonstrated in the tabulated results for Apples at Ridgmont. The comparisons of results are between those of less than normal applications of manure, normal, and more than normal. The "less than normal," in some cases, if not in all, include the results of no applications of manure, but as the results of small dressings are incorporated with those of none, there is no comparison between the products of manured and unmanured plots. Mr. Pickering may have abundance of evidence to prove that Apple trees and their crops at Ridgmont have not generally been benefited at all by manures, but all that his tabulated results, with one exception, show is that no peculiar advantage has been gained by increasing the dressings of manure described as "less than normal." The obvious comment is that even a small dressing annually may have been made for the trees, so that any extra quantity was mere surplusage, which, on the whole, did no good.

The results of manurial experiments on Apples at Ridgmont recall to memory those given in a Bulletin issued from the New York Agricultural Experiment Station in 1911, entitled "Is it Necessary to Fertilise an Apple Orchard?" In this case the results of various dressings of manure, including dung, for fifteen years, were compared with those of undressed land, with almost as general a lack of benefit from the manures as is indicated in the report for Ridgmont. Incidentally, however, it was stated that a cover crop was grown every year and ploughed in. Therefore, there was no comparison between no manure and manure, as liberal green manuring was carried out annually, and this, apparently, was all that the trees required.

The results of manurial experiments on Apples at Millbrook, where the soil is lighter and less rich in available potash than it is at Ridgmont, are strikingly different from those of the latter station. At Millbrook the general average results of manuring with artificials and dung for six years are given as follows:—

	Less than Normal.	Normal.	More than Normal
Leaf size	98.5	100	100.7
Weight of Prunings	85	100	129
Weight of fruit	75	100	135
Size of fruit	81	100	196

The weight of prunings indicates growth of new wood. For Millbrook we have the results of no manure tabulated in the detailed statistics. Taking the results of no manure as 100, a single dressing of artificial manures, including nitro-

FIG. 62.—INFLORESCENCE OF SELAGINELLA IRRORATA. (¼ NAT. SIZE.)

(See p. 134.)

gen, phosphoric acid, and potash, gave 111; a double dressing 120; and a treble dressing 163 in weight of prunings; while the corresponding figures for weight of fruit are 111, 142, and 163; and those for size of fruits are 132, 132, and 165. For dung the results are still more remarkable. Still taking 100 represent no manure, the figures relating to weight of prunings are 154 for a single dressing, 215 for a double, and 227 for a treble dressing; while the corresponding figures for weight of fruit are 156, 186, and 242; and those for size of fruits are 191, 272, and 251. The increases are all the more remarkable considering the fact that the Millbrook plots have been allowed to run to grass. A single dressing of dung is 12 tons per acre, and it might have been supposed that this applied annually would have been ample. The figures show, however, that in weight of fruit, as well as in growth of new wood, the double dressing gave extra advantage, while the treble dressing of 36 tons per acre annually increased the growth and fruit still more. The increase in weight of fruit is more astonishing than the augmented growth of new wood, because liberal manuring is expected to force wood growth, whereas such forced growth is usually against the production of fruit. It can hardly be supposed that the application of so great a quantity of dung annually would prove remunerative, or that it could be obtained by all growers in extensive fruit districts, even if they desired to apply it.

The results of omitting in turn from the complete dressing of artificial manures each of the constituents are interesting, but puzzling. When potash was omitted there was a great decrease in wood growth and weight of fruit; but the omission of phosphate showed increases in both cases over the results of the complete manure, while the omission of nitrogen made no considerable difference. Mr. Pickering explains that the soil at Millbrook contains sufficient phosphate and a fair supply of nitrogen; but, in reference to the latter, he states that as the soil is a coarse sand, nitrate of soda is quickly washed out of it. It might be supposed, however, that a soil which loses nitrogen easily would need specially to have it supplied frequently.

Experiments on Gooseberries, Red Currants, Raspberries, and Strawberries were carried out at Ridgmont. Those on Gooseberries gave the most remarkable results of any mentioned in the report. Although neither artificial manures nor dung had any considerable effect upon Apples on this farm, so far as the tabulated results show, both, and particularly dung, had a great effect on Gooseberries. Taking 100 as representing the produce of unmanured land, artificials equivalent to 12 tons per acre of dung gave 116 as the average of 15 years, and when the quantity was equivalent to 30 tons of dung, there was a further increase to 207. When dung itself was applied the increases were vastly greater, rising to 656 for 12 tons per acre, and 1,210 for 30 tons. Moreover, the effects of the dung were cumulative, the crops of the last two years of the period being represented by the figures 1,850 and 1,220, against 100 for unmanured land. A great proportion of the bushes on the unmanured land died before the end of period, only 23 remaining out of 180 in the last year. The deaths were much less, but still considerable, on the artificially manured plots, but comparatively small on the dunged plots. Red Currants and Raspberries responded moderately to dressings of artificial manures, but much more to dung, though not nearly to the same extent as Gooseberries. The results of manuring Strawberries were too irregular and disappointing to allow of any lesson being derived from them.

PLANT NOTES.

PRIMULA VEITCHII.

Of the Primulas which have come to us from the Far East within the last few years P. Veitchii ranks as one of the "easy" growers. It has found its way into a good many gardens, and is a plant which is exceedingly obliging in its ways, flourishing in almost any soil, but showing a preference for good new loam and old leaf soil. A little well-rotted cow manure renders it still more vigorous. It has prettily formed leaves, soft-looking in their texture and of a good green colour. The flowers are a kind of magenta-purple; purists in colour-tones assert that they are rather aggressively magenta. But a good deal must be forgiven to a plant which grows so satisfactorily as Primula Veitchii.

It will grow in the border in the rock garden, and even in a moraine if it has access to some good soil beneath the upper layer of gravel or chips. It likes partial shade, but can be grown in full sunshine if not too dry a place. Propagation is effected by division or seeds. *S. Arnott.*

ON INCREASED FOOD PRODUCTION.

DWARF BEANS IN FRAMES.

Good crops are obtained from Dwarf Beans grown in frames on hot beds. Four-lighted frames are the best to use, as the whole structure can then be easily raised as the plants grow. Seed should be sown singly about the middle of March in 3 inch pots, and placed in a warm house to germinate. About 8 inches of soil should be placed on the hot-bed, using similar soil to that in the pots. Care must be taken not to let the plants grow too large before planting. The main shoots should be pinched out a day or so before planting. Allow 14 inches each way between the plants, and support the side growths with small sticks obtained from half-worn Birch brooms. The lights must be kept closed until new growth is visible, but afterwards ventilate when the weather is favourable. Syringe the plants twice a day, but not enough to saturate the soil. Lightly dust the surface soil with soot to ward off slugs and act as a stimulant to the growth. *C. Davis, Holy Wells Park Gardens, Ipswich.*

LETTUCE

To raise Lettuces successfully under glass, every care is necessary to prevent the plants from getting crowded and growing weakly. If the seeds are sown in gentle warmth the boxes should be removed to cool houses directly germination commences. Place the boxes in a cool, light, airy house, where the plants will grow sturdily, and later prick the Lettuces off 2 inches apart into other boxes. When they have made sturdy little plants about one inch high transfer them to cold frames, and admit air freely. The lights should be removed when the weather is favourable, and air admitted to the frames at night, when there is no danger of frost. Take the boxes out of the frames for a week or ten days before the Lettuces are planted out in order to harden the plants.

Seeds may be sown direct in the soil in a frame, and the plants thinned when large enough. A sowing may now be made in the open, and successional sowings at intervals of three weeks until the middle of June. Any rough, low frames are suitable for raising Lettuces. All that is really needed are a few boards nailed to stakes driven into the ground. If these are covered with lights they answer as well as frames of the best quality.

The ground for Lettuces needs to be deeply dug in autumn, but where this cannot be done, let it be dug as early in the year as it can be cleared of other crops. On that dug early manure should be wheeled during frosty weather, and left in heaps ready for spreading some time previous to planting. I prefer to do this and fork the manure in at the same time, breaking up the soil well as the work proceeds. All the land that was turned up roughly last year became thoroughly pulverised, and was in excellent condition for planting after it had been forked over and left for two or three days. Lettuces grow freely in well-worked soil, and if the surface has become fine from exposure the seedlings are easier to plant and grow more quickly than when the soil is rough and lumpy at planting time.

Lettuces dislike fresh manure, but the roots take to rotten manure freely

Give the plants in the boxes a good watering a few hours previous to planting them; the roots will then lift with plenty of earth attached, and may be transplanted without check if the work is done carefully with a trowel. Shallow drills one foot apart should be made as planting proceeds, and the plants placed one foot apart in the row. After they commence growing the hoe should be run through the ground to loosen the surface. The more the hoe is used the quicker the plants will grow, and they will be ready for cutting fully a fortnight earlier than those that are only hoed to keep down weeds. Applications of soot strewn over the bed in their early stages during showery weather assists growth.

During hot, dry weather Lettuces do better on borders that are not fully exposed to the sun. North borders can be selected, and if 3 inches of the sifted material of a spent Mushroom bed be laid over the soil it will keep the roots cool and moist, save much watering, and benefit the plants considerably; but those who grow large breadths for the market cannot well practise these methods. They are not essential if the ground has been well worked, liberally manured, and the hoe is kept constantly at work. *James A. Paice.*

LIME.

Lime possesses alkaline properties which neutralise or counteract soil acidity. Sour soils encourage disease in Potatos, and wherever diseased tubers were dug last season lime should be applied to the soil this season before planting commences. Wherever pig or farmyard manure, sulphate of ammonia, or nitrate of soda is used lime should be present in the soil, as without lime the manures cannot perform their proper function. Lime is especially valuable on dry land, as it helps to liberate the potash present.

Lime on a clay soil not only liberates plant food, but it assists drainage. It is well known as a fungicide and a remedy for the prevention of club root; therefore land intended for the cultivation of Brassicas, and especially the soil for the seed-bed in which the plants are raised, should receive a light dressing of lime previous to planting or sowing. Club-root often originates in the seed bed, and if not checked, may be carried to other parts of the garden when transplanting the seedling Brassicas.

Lime may be applied to the soil in several forms, the most common being that of slaked lime. For this method fresh burnt lime (quick lime) may be placed on the land in small heaps, covered with soil, and allowed to slake naturally. When it has become a dry powder mix it with the soil that covered it, and spread it evenly over the land so as just to whiten the surface soil. When small quantities are only occasionally required air slaked lime can be used, or the quick lime can be kept in a dry building until it slakes naturally, when it may be used as occasions require. *G. H. H. W.*

LEEKS

Mr. Thatcher (p. 104) states that the Leek is one of the hardiest of plants, and one of the most useful vegetables. With him, so far, I agree, but the method he advocates in cultivation is not reasonable now that labour is so scarce.

The saving of unnecessary labour is of the first importance in the cultivation of all crops, and I beg to point out to your correspondent that most serviceable Leeks may be grown without the aid of fire-heat in glasshouses or cold frames (unless early produce is required); in fact, very few cultural details described by Mr. Thatcher are required in the production of Leeks for ordinary use. Certainly the Leek requires good cultivation, but there is no need for coddling the plant. The Leek is one of the most useful vegetables for growing as a catch crop, as the plants may remain in the seed-bed without much injury until land becomes vacant.

Good serviceable Leeks may be obtained by sowing in the open during March, and when sufficiently large transplanted on well manured land into holes 7 inches to 8 inches deep made with a setting peg, in rows 12 inches apart, setting the plants out to about 9 inches apart in the rows. The plants should be well watered as they are planted. The subsequent treatment consists in keeping down weeds and stirring the surface soil on frequent occasions during dry weather. *G. H. H. W.*

The Week's Work.

THE KITCHEN GARDEN.

By F. Jordan, Gardener to Lieut.-Col. Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Potatos. In gardens in warm districts the general planting of this important crop may be proceeded with when the soil is in a workable condition. No hard-and-fast rule can be laid down, as the weather during spring changes quickly, and the nature of the ground must always be taken into consideration. Seed Potatos are cheap and plentiful, and those who recognise the advantage of a change of seed and the selection of suitable varieties will be assured of an increased crop. Early varieties with moderate tops may be planted one foot apart and 2 feet between the rows; late varieties with stronger haulm need a distance of 2 feet 6 inches between the rows. The young shoots are very tender, and a little fine soil should be drawn over them on the least sign of frost.

Peas.—Successional sowings of Peas should be made at short intervals, according to the demand, in deeply cultivated and well prepared ground. A few isolated rows, liberally treated at the roots, will produce more Peas of better quality than double the number of plants crowded together and starved. If suitable stakes are available choose tall growing varieties, as these produce the finest pods, and are the most profitable. Those who prefer dwarf varieties have choice of such sorts as Daisy, Peerless, Rentpayer, Stratagem, and those recommended in previous calendars. Early Giant, Senator, Centenary, Hercules, Glory of Devon, Stourbridge Marrow and Duke of Albany may all be relied upon, with Gladstone, Ne Plus Ultra, and Autocrat for latest supplies.

Broad Beans.—Make further sowings of Broad Beans. Seville Long Pod and Bunyard's Exhibition are large podded sorts, and amongst the most useful varieties.

Turnips.—Make further small sowings of Early Milan and Snowball Turnips on a warm border, covering the seeds with light soil or wood ash. Thin the seedlings early and make further sowings if the earlier seedlings have been checked by frost or other causes.

General Remarks Many other seeds than those already recommended need to be sown this month and in April, such as Broccoli, Kale, Brussels Sprouts, Cabbage, Cauliflower, Celery, Lettuce, Parsley, Savoy, and Spinach. A word of caution is necessary, as when plants of various kinds of vegetables are raised long before they can be finally put out, a bad start is made, and many failures may be traced to early sowing. Plants sown in April will, with ordinarily good culture, grow to a good size by the end of May, or by the time it is safe to plant them out. By all means raise early supplies where attention and protection can be afforded the crops, but the seedlings must not be neglected in any way. Small sowings at short intervals are best at this early season.

THE ORCHID HOUSES.

By J. Collier, Gardener to Sir Jeremiah Colman, Bart., Gatton Park, Reigate.

Mexican Laelias.—The majority of plants of Laelia anceps will have passed out of bloom, and any necessary repotting or top-dressing should be done as soon as new roots are observed to be emerging from the base of the last developed pseudo-bulbs. Rather deep pans without side holes filled with Osmunda or A 1 fibre cut up rather roughly will suit their requirements. Specimens growing in receptacles sufficiently large for the next season's growth should not be disturbed, but the old compost that has become loose and decayed should be removed from between the roots with a pointed stick, the small particles washed from the drainage, and new materials substituted. Plants that have outgrown their space and become open in the centre should be taken out of the pans and useless

pseudo bulbs and all decayed roots cut away, leaving only three or four behind each lead. If large specimens are desired place several growths in the same receptacles; or to increase the stock of any particular variety the portions may be potted up separately. The pans should be filled to one half their depth with clean crocks for drainage, the rhizomes resting on the surface of the compost, which should be level with the rim of the pan. Press the materials rather firmly around the rhizomes, and insert some pieces of crock at intervals to ensure a free passage of water. After repotting, water should be poured around the outer edges of the soil to induce root action. If too much moisture is applied at this stage the roots will decay, but as the season advances the amount of water should be increased, and atmospheric moisture maintained by frequent overhead sprayings.

COELOGYNE CRISTATA.—After passing out of flower plants of Coelogyne cristata will soon commence to push forth new roots from the base of the young growths, and should be repotted if necessary. Specimens that have overgrown their receptacles and are in an unhealthy condition may be broken up and the portions made into smaller plants. Healthy plants that have sufficient rooting space should not be disturbed in any way. Those that require repotting should be afforded ample drainage, and a compost consisting of equal parts good fibrous loam, Osmunda fibre or A 1 fibre, and sphagnum-moss. After repotting the plants should be shaded from bright sunshine, watered sparingly at the roots, and frequently sprayed overhead until root action commences. When well rooted they will require copious supplies of water each time the soil becomes fairly dry. This useful species is easily cultivated and has a vigorous constitution; it will thrive in almost any house with a intermediate temperature.

FRUITS UNDER GLASS.

By W. J. GRISE, Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

EARLY VINERIES. Important work needs to be done now in early vineries. Assist in thinning the bunches, stopping the shoots and gradually tying the shoots to the wires. Young vines should not be cropped excessively, for although the Grapes may be satisfactory for the one year, and the berries finish well, the vines in the following season will exhibit weakness. Regulate the cropping according to the strength of the vine, remembering always that colour and finish of berry are the two essentials in Grape culture, and these cannot be achieved if the resources of the vine are taxed to their utmost. The thinning of the berries should be done at the earliest opportunity, for delay in this respect throws an unnecessary strain upon the vines. After thinning the bunches, mulch the inside borders with short stable manure, and well water them, especially portions under the hot water pipes. Damp the bare spaces twice daily with tepid water and twice or thrice weekly with diluted liquid manure. Soot water may be placed in the evaporating troughs, or syringed about the house, without wetting the bunches; soot water used in this way has an invigorating effect on the foliage.

EARLY FIG HOUSE.—The fruits on early Fig trees show signs of swelling, and the day temperature may be increased a little. On mild nights admit a little air through the back ventilators, and let the night temperature range about 65°. As the season advances, and the sun gains power, large trees growing in restricted borders will require liberal supplies of water and stimulants if the crop be a large one. Care must be exercised in feeding the roots, for an excess of stimulants would cause gross, unfruitful wood to develop. Top dressings of turf, mortar rubble, and a little wood-ash encourage the growth of surface roots that are so necessary to fruiting. If the crop is a large one, the fruits should be thinned, and it is not advisable to delay the thinning, or the fruits will fall in considerable numbers. Overcropping and spasmodic temperatures are the chief causes of fruit dropping, and I am convinced that if the thinning be done in the early stages, by removing all misshapen, badly placed fruits, and the night temperatures kept fairly steady, there will be no trouble in this respect, provided, of course, that the trees are not suffering from drought at the roots. Syringe the trees twice daily except in dull weather, and expose them fully to the light. Pinching, disbudding and removing superfluous shoots will keep the trees free of useless growth and expose the fruiting shoots to the sun and air.

LATE FIGS.—All necessary work in the late Fig house should be completed at once, and the trees made ready for starting. If the borders have been top-dressed and watered the buds will soon commence to swell. Where these late houses are heated, the amount of ventilation may be reduced at night, and, in cold weather, the hot water valves opened a little, otherwise the ventilators must be opened to their fullest extent by day and a moderate amount of air allowed to enter at night, except in frosty weather, until the season is further advanced. These late trees will only finish one crop of fruit well.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

THE WATERING OF FRUIT TREES.—On light soils, and where the drainage is free, many fruit trees suffer early in the season for want of water. We have had a remarkably dry spring, and the ground is hardly moist. Apricots are flowering well this year. These, and some other trees that are somewhat high and dry, on which there is an abundant show for blossom, will shortly be watered. The ground under the fruit trees should be kept well hoed, so that all available rain will penetrate, instead of passing off. Let all newly planted fruit trees be watered, if occasion arises. Do not crop vegetables too close to these trees. Where the young growth is not coming away as it ought to syringe the trees on all bright days. In the case of choice trees, or others larger trees than the average trade size have been planted, it will be advisable to mulch them at any rate for the first season. If the trees be of extra size the stems should be encircled with hay bands to keep the main stems moist. Do not be tempted to take any fruit from newly planted trees the first season, but rather try to build them up for another year's crop.

ESPALIER TRAINED TREES. See that all shoots or branches are nailed or tied in before too much sap is caused by weather trees. See also that the supporting trees are sound and not to over-specimens.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

ANNUALS FOR BEDDING. Sow hardy annuals in flower beds, either broadcast or in lines. For fine seeds, such as Godetia Schammi fl. pl. (Double Rose), Silene Armeria, and Malcomia maritima, the first named method is preferable. The seeds are distributed most evenly and with least waste when mixed with fine, dry sand, and scattered over the bed or border. For larger seeds, such as Saponaria calabrica, Marigolds, Xeranthemum annuum, Nemesia, and Chrysanthemums, shallow drills should be opened and the seeds be very thinly arranged therein.

HALF-HARDY ANNUALS.—Sow half hardy annuals in shallow beds of light soil in cold frames, either in drills or broadcast. If the latter, give more space to the seedlings, and place a thin layer of light soil over the seeds. It will save watering if some shading material is spread over the sashes until the seedlings appear. French and African Marigolds, Tagetes signata, Salpiglossis, Schizanthus, Nicotiana affinis, and Zinnias succeed better when sown thinly in boxes in moderate heat. If sown thinly and transferred to a frame shortly after the seedlings appear, they need not be transplanted until they are ready to be transferred from the seed-boxes to the positions they are finally to occupy.

PRIMROSES AND POLYANTHUSES should also be sown shortly. Beds should be prepared for them on a border in the kitchen garden, the seeds being scattered rather thickly all over the surface of the beds, then patted down with the back of a spade and a very slight sprinkling of fine soil over all, which also should be patted down. I have frequently raised Carnations in a similar way, only they are sown in shallow drills, and in firm soil.

GALTONIA.—When set very early, Galtonias flower as a rule too soon to be useful in autumn. The bulbs should be buried 4-5 inches in depth, and the plants can be used effectively in a variety of ways; arranged in large groups, used as dot plants, or mixed with Gladiolus brenchleyensis. Seeds may be sown at once in the open, and left in the seed-bed until the bulbs have attained a flowering size. The little bulblets or offsets produced in many kinds of Gladiolus may be treated similarly. These are of much value for increasing stocks, and they yield finer spikes if not allowed to bloom too soon than do corms produced from flowering bulbs.

SWEET PEAS. Sweet Peas in pots should have all the fresh air possible, but with means at hand to protect them from frost or cold winds, which are injurious to them. Slight manurial applications will benefit well rooted plants. In the more northerly parts seeds may be sown in the open, allowing for the ravages of mice when arranging the seeds.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

STOVE PLANTS. Any necessary repotting of stove plants should be done before the weather becomes warm. Prepare enough soil to pot the whole of the plants which need it, and place it on the stage at one end of the stove to get thoroughly warmed through before potting commences. A compost suitable for potting most stove subjects consists of fibrous loam, peat, decayed leaf soil, crushed charcoal and sharp sand in suitable proportions. The potting of stove plants must always be done firmly. See that the pots are thoroughly cleaned, and well drained with clean potsherds. For a few weeks after potting the plants need very careful handling; a check of any kind will cause the loss of some of the lower leaves. Lightly spray them two or three times a day with lukewarm rain-water, and frequently damp all bare surfaces in the house, to keep the atmosphere moist. Recently potted plants must not be exposed to bright sunshine until the roots are again active. Much care is necessary in watering the roots until they have become established in the new soil.

BEGONIA GLOIRE DE LORRAINE.—No time must be lost in getting the main batch of cuttings rooted. Cuttings of most plants will root more freely now than later when the weather is warmer. Cuttings of this Begonia are not so liable to damp off if they are inserted in finely sifted sand; the sand must be made quite firm, or it will dry too quickly. A batch may be grown in baskets for hanging from the roof of the conservatory, where they are very effective. A late batch of cuttings should also be propagated for flowering in small pots for table decoration.

CARNATIONS.—Young plants must be potted on before the roots become pot bound. Plants which are now growing in 3-inch pots may be transferred to 5-inch. A compost of good fibrous loam, with enough crushed brick rubble and wood ash to keep it porous, will suit them. Pot firmly, but take care not to damage the roots. Place the plants when potted on a shelf near the roof glass, and keep them shaded from bright sunshine until the roots are again active.

CYCLAMEN.—The flowering season of Cyclamen is now almost over. Before discarding the old plants, some of the best varieties should be selected for potting on. These old plants often make finer specimens than those which were raised the previous autumn from seed. After flowering, place them closely together in a cold frame and keep them rather dry for a few weeks, they may then be partly shaken out and repotted into 6-inch or 7-inch pots, according to the size of the corms. When potted, plunge the pots in ashes in a shallow frame quite near the glass, and afford water sparingly until roots are plentiful. The young plants which were raised last year must be kept growing in a genial atmosphere. Pot them on when necessary in a light compost. As the weather becomes warmer, gradually reduce the fire heat, eventually plunging them in ashes in a cold frame.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41 Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith*

APPOINTMENTS FOR APRIL.

TUESDAY, APRIL 2
Scot. Hort. Assoc. meet
THURSDAY, APRIL 4—
Manchester and N. of England Orchid Soc. meet.
TUESDAY, APRIL 9—
Roy. Hort. Soc. Comm. meet.
THURSDAY, APRIL 18—
Manchester and N. of England Orchid Soc. meet
TUESDAY, APRIL 23—
Roy. Hort. Soc. Comm. meet. National Auricula and Prim. Soc. Annual Exhibition, London.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 45.6.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Wednesday*, March 27, 10 a.m.: Bar. 30, temp. 46.5°. Weather—Dull

Theophrastus.

The present time is destroying many illusions which have obscured correct perceptions in many departments of human interest. For something like half a century the alleged superiority of the German in science as well as in some other walks of life has been continuously trumpeted forth by the writers of the Fatherland till their statements have almost come to be accepted at their face value by nations whose self assertiveness happens to be inferior to that of the Teutons. In things botanical this has been greatly helped by the so called history of botany written many years ago by Julius Sachs. Everyone reading this work (of which there is an English translation) would naturally be impressed with the view that outside "German botany" there was little or nothing worthy of his serious attention. The older writers in particular are dismissed as being little more than grandiloquent muddlers. Aristotle and Theophrastus were pernicious triflers, obscuring all that was scientific by nebulous philosophy. Even Caesalpino, one of the ablest writers of the sixteenth century, while grudgingly admitted to be within measurable distance of genius, is held to have been miserably seduced from the path of science by the influence of the old Greek writers. It is with special interest, then, that we welcome the admirable translation by Sir Arthur Hort of the "Enquiry into Plants,"* which was written by Theophrastus about 2,200 years ago. A perusal of this book, now so well rendered into English, enables us to gain a vivid impression of the wealth of observation, ordered and synthesised by a very acute mind. In spite of much that is mythical and obscure, it fills us with admiration, for it is a veritable treasure-house of information and of thought which has lain practically hidden from modern botanical and horticultural students. One comes, indeed, to realise the gulf that separated the gifted and intellectual Greek from the clumsy hodmen so characteristically proclaimed by Sachs as the "German Fathers of Botany."

It must, however, be borne in mind, when attempting to appraise the importance and value of such a work as that of Theophrastus, that the methods which have resulted in the development of modern science were almost entirely undeveloped at that remote era. Facts, of course, had their value, but there was no wealth of painfully acquired experience to draw upon which should direct what we now call scientific inquiry into fruitful channels. There were no sign-posts in those days to distinguish the paths that broaden out into the wider avennes of knowledge from the many tracks that lose themselves in the morass of error.

The book is full of interesting observations and reflections, and these are enough to show how far men had even then advanced in the useful knowledge of the vegetable kingdom. Parts of it, indeed, recall chapters to be found in botanical and horticultural works written within the recollection of many of us. The main structures of plants, the stems, leaves, roots, &c., of plants are recognised, and their more important peculiarities and properties are discussed in a way in which modernity is oddly mingled with the flavour of antiquity. Although it is evident that the processes leading to the formation of the fruit were not clearly understood, it is plain that the need for pollination was at least partially grasped, and that its significance, so far as essentials are concerned, was more clearly recognised in ancient times than by the "German Fathers of Botany" some 1,900 years later.

In not a few of his chapters Theophrastus offers interesting and even instructive reading to-day. Thus in the pages devoted to timber, its qualities, and the conditions that affect its value, the discussion would hardly compare unfavourably with that to be found in more than one modern treatise. But quite apart from utilitarian considerations, the light thus cast on ancient methods of cultivation cannot fail to excite pleasure in the minds of those whose interest in botany or horticulture extends beyond current theory and practice. Theophrastus divided the vegetable kingdom into Trees, Shrubs, and Herbs, a basis of classification which persisted even in the works of our own distinguished fellow-countryman, Ray, who flourished in the seventeenth century. And, indeed, from the point of view with which the older writers were mainly concerned, it was probably as good as, if not actually better than, any other system which could have been devised.

It is naturally impossible in this place to attempt to give an adequate account of the botanical work as a whole of Theophrastus, but perhaps enough has been written to indicate the general character of the treatise that now lies ready to the hand of anyone who wants to know something of botany and horticulture as it was understood in those ancient days.

It is fortunate that the task of translation should have fallen to a scholar who is also a successful horticulturist, for no small difficulty in a work of this sort consists in the identification of the plants known to and described by the old writers. Sir Arthur Hort has attacked the problem with a considerable measure of success, and he has also made plain some of the structural features, *e.g.*, the glumes and palea of Wheat, which are somewhat ambiguously referred to in the original text.

There are a few slight errors in nomenclature, *e.g.*, in the use of the word Sycamore for Sycomore (Fig), which can easily be amended in a future issue; and most people would recognise Muscari comosum more readily as the feathered Grape Hyacinth than as "purse-tassels." But, after all, these are not very serious faults, and do not greatly detract from the excellence of the translation as a whole.

The inclusion of the book in the Loeb Classical Library is in itself a guarantee of good technical work on the part of the publisher, and the presentation of the Greek and English text on opposite pages will appeal to those who desire to compare the two. A good index of the Greek plant names, together with the key indices in English and Latin, add in no small measure to the value of a book of exceptional interest and merit.

* *Theophrastus.* Enquiry into plants, and minor works on odours and weather signs. With an English translation by Sir Arthur Hort, Bart., M.A., formerly Fellow of Trinity College, Cambridge. In two volumes. (London: William Heinemann; New York: G. P. Putnam's Sons.) MCMXVI. Price 10s.

TUESDAY'S MEETING AT THE SCOTTISH DRILL HALL.—The fortnightly meeting of the Royal Horticultural Society was held as usual on Tuesday last. The show was a small one, and there was only a moderate attendance. Orchids again constituted the principal feature of the exhibition. The most interesting plants contributed by the Orchidists were Dendrobium Alpha var. Eleanor and Brasso-Cattleya Doris Langley variety. A report of the meeting will be published in our next issue.

SUPPLIES OF SUPERPHOSPHATE.—Owing to an unexpected increase in the output of superphosphates, there is a possibility that farmers and allotment-holders may be able to secure additional supplies. They should place their orders at once with their usual merchants or co-operative societies, even if they require delivery so late as May. If merchants say that no further supplies are available, inquiry should be addressed promptly to the Food Production Department, 72, Victoria Street, S.W. 1. Superphosphates are especially valuable in increasing the Potato crop. An Order is about to be issued

nxing the prices for the sales of small quantities from merchants' stores.

Government Prices for Potatoes.—The letter of Mr. J. R. Clynes, Parliamentary Secretary to the Ministry of Food, in the *Times* of March 20, refers to the method of payment for Potatoes of the 1918 crop to be taken over by the Government. It has been suggested in some quarters that the prices to be paid would be inequitable owing to the fact that farmers in the southern counties do not expect a crop much more than half as large as that gathered from the Fens and warp lands of Lincolnshire. As Mr. Clynes points out, Lord Rhondda's scheme provides that the purchase price of this year's Potatoes will be assessed ultimately with due regard to the size of the crop and the quality of the produce. "The intention," says Mr. Clynes, "is that a Joint Commission of the Board of Agriculture and the Ministry of Food shall visit each area in which Potatoes are grown and assess the price locally after hearing evidence from representative growers as to the yields obtained, the quality of the Potatoes and the cost of production. The prices actually quoted in the scheme are only minimum prices, and are intended to meet the case of what are ordinarily the cheapest Potatoes, for those grown on the black lands of Cambridgeshire." Mr. Clynes further points out that the "increased acreage" is to be calculated on the acreage under Potatoes in 1916, which was the largest for some years past. Consequently, farmers are likely to be treated more liberally than a mere comparison with 1917 would seem to warrant.

A Tree Yucca.—The tree Yuccas of America have their counterpart in New Zealand, where there are no Yuccas, the Cabbage or Tī trees Cordyline australis and others representing them there. The dividing line between Yucca and Cordyline is an arbitrary one. For example the plant illustrated in fig. 63, which is now known as Yucca gigantea, was for many years known in gardens as Dracæna or Cordyline yuccoides. It is represented in the Temperate House at Kew by a tall specimen which flowers every year, and is by far the largest Yucca there, being about 35 feet high, with leaves 4 feet by 4 inches and erect panicles of creamy white flowers not unlike those of Yucca gloriosa which flowers frequently in gardens. A still larger Yucca, Yucca elata, which was introduced in 1894 from a garden at Cannes, had a short career in the same house at Kew. It had a clean stem of 25 feet and 5 feet in diameter at the base, but it never became established and died without flowering. Yucca elata is one of the most remarkable and interesting trees of North America. It has the dimensions of an Oak, long and branching, 70 feet or so high, the trunk 5 feet in diameter, and the leaves, gathered in panicles 6 feet long, bear large white star-shaped flowers. In the distance the [illegible] seems a mass of fruit at the ends of the branches. There are other handsome Yuccas in the Southern United States. They are unfortunately less hardy in their native state in the south-east of the United Kingdom, and as they are not suitable for greenhouse cultivation, they, like other American plants, are beyond the pale of British horticulture. But this does not apply to Y. guatemalensis, which is as hardy in a big cool greenhouse as the tree Coniferæ. The specimen at Kew is more than 50 years old.

Allotments.—Up to last week-end 242,000 plots had been laid out for allotments under the Cultivation of Lands Order, 1917. Additional areas of Wandsworth Common, Garratt Green, Streatham Common, and Tooting Bec Common have been provisionally scheduled for allotments. Thirty-five local authorities last week agreed to take steps to acquire 440 acres of land for allotments. The largest acreage added is that of Camberwell, with 40 acres and 600 allotments. Hendon comes next with 36 acres and 540 allotments. Other figures are: Edmonton, 27 acres (405 allotments); Willesden, 24 acres (360 allotments; Enfield, 23 acres (345 allotments); Wandsworth and Reigate, 21 acres and 315 allotments each; Birkenshaw, Otley, and Bilton, 20 acres each; Willerby, 19 acres; Rotherham, 20½ acres; Hale, 15 acres; Guildford, 14 acres; Swinton (Yorks.), 11½ acres; Leyton, 11 acres; and Hellaby, 12 acres.

Soda for Potato Spraying.—The Food Production Department has arranged with the principal manufacturers of soda crystals to supply the product during the ensuing season at £4 7s. 6d. per ton net in 2-cwt. bags delivered to any station in England, Scotland, and Wales in 5-ton lots. In large cities and other approved centres lots of 1 ton and upwards will be supplied at the same price. For lots of less than 1 ton, orders should be placed with local dealers. The retail price of soda crystals sold from shop or store ought not to exceed the following: 56 lbs., 3s. 6d.; 14 lbs., 1s., 7 lbs., 6d.; 1 lb., 1d. Horticultural associations, farmers, allotment holders and others should make arrangements to combine their requirements, and to place orders at once with manufacturers or dealers for lots of 1 ton and upwards or with dealers or retailers for smaller quantities. If any difficulty occurs in obtaining supplies, the Food Production Department, 72, Victoria Street, London, S.W. 1, should be communicated with.

The Value of Soot.—Good soot contains at least 3 per cent. of nitrogen, and is specially suitable for all members of the Cabbage family and other crops as well as being beneficial to all crops during the early summer, if sown between the rows. It also darkens the colour of the soil and increases its power of absorbing heat. A dressing, equivalent to the usual application of sulphate of ammonia, would be at the rate of 10 cwt. or 40 bushels per acre, or 7 lbs. per rod. Heavy applications should not be given to the foliage of tender crops, such as Carrots, or burning may result. Soot should be stored under cover for a time before it is used on a growing crop. A good sample weighs 23 lbs. per bushel; heavier samples are usually of poorer quality.

ROYAL VISIT TO READING.

WE now give further details of the Royal visit to Messrs. Sutton and Sons' seed establishment at Reading, announced in the issue for March 16.

Their Majesties the King and Queen were received at the entrance of the premises by the proprietors, Mr. Arthur W. Sutton, Mr. Leonard Sutton, and Mr. Martin H. E. Sutton, and conducted to the Museum Reception Room, where the visitors' book was signed, and various presentations made.

After a few introductory words by the senior partner on the founding and history of the firm and the work carried on, their Majesties inspected the very interesting collection of exhibits there arranged, which comprised the wild types of Solanum, the berries and seeds of the Potato preserved specimens of tubers showing the diseases to which the Potato is liable, together with

A large collection of the seeds of all kinds of Peas and Beans showing the varying coat colours proved of considerable interest, as also did specimens and models of many types of vegetables, together with their respective seeds.

A fine exhibit of Lumière transparencies, showing many vegetables and beautiful flowers in their natural colours, was much admired, as were also the educational examples of grasses and Clovers, and the cases containing insects injurious to farm and garden crops.

Samples of radioactive ores, which at one time it was hoped would prove of manurial value were examined, as also were the many publications issued by the firm, the contrast between the first edition of Mr. Martin Sutton's *Permanent and Temporary Pastures* and the present day issue being specially marked.

After inspecting the Roll of Honour containing the names of over 220 employees on active

FIG. 64.—ROYAL VISIT TO READING. H.M. THE KING IN MESSRS. SUTTON AND SONS' SEED TESTING LABORATORY.

up to date commercial varieties, and many photographs of scientific interest.

Their Majesties were much interested in the many useful forms of the genus Brassica, such as Cabbage, Kale, Savoy, Brussels Sprouts and Broccoli.

The extraordinary development of the Beet and Mangold from the wild type, showing the range from the garden forms to the enormous roots of Mangolds used as food for cattle, together with Sugar Beet for the extraction of sugar, was of special interest.

Mr. Arthur Sutton explained the methods of selection and seed production, showing types of roots used as "mother roots" for the production of "stock seed," and the plants which are used for the growing of commercial seed.

Their Majesties then examined the wild Pea found by Mr. Sutton growing wild in Palestine, a very primitive type, and saw models of the present day varieties, pods of which have been grown up to 8 inches in length.

service, their Majesties made a tour of inspection of the various departments.

In the Shipping and Export Office the Royal visitors were much interested in a chart of the world showing every place where the firm has a distributing agency. Photographs showing the cattle in New Zealand feeding on roots grown from seeds sent out by the firm, were commented upon.

Passing through the Pea Granary, the Vegetable Seed Room was visited, where over a thousand orders are being executed daily, and where the Royal party was able to see in execution many commands from the Army and Navy Canteens' Board for seed to produce vegetables in the military districts of this country and overseas.

The Drying Room for removing the superfluous moisture from seeds before they are sent across the tropics was of special interest, as also was the large Farm Seed Order Room, where root and other seeds are got ready for dispatching to customers.

The Royal Party then proceeded to the Farm Seed Stores, which have a capacity of over 500,000 cubic feet, and noticed the enormous quantities of root and grass seeds, and inspected in detail the special seed-cleaning machinery and the process of mixing grass and Clover seeds.

The Seed Testing Laboratory was next visited by their Majesties (see fig. 64), where samples of food-producing seeds are tested before distribution, and the analytical purity determined by aid of the microscope and other instruments.

The Loading Floor, from which goods are despatched to the stations, was passed through on the way to the Pea Picking Room, where imperfect seeds were being removed from large quantities of Peas and Beans. This work is done by women.

The "Stock Seed" Room, containing all the "Mother Seeds" from which the supplies are grown, was noticed, and in the Flower Seed Order Room a large order from the Director of Graves Registration, B.E.F., for seeds for beautifying the military cemeteries in France, was being prepared for dispatching.

In the Potato Department large quantities of Potatos and Artichokes for the various base depots at home and in France were being got ready, women carrying out the work formerly done by men.

Their Majesties then saw the Despatch Office, and also the Invoice Office, where girl typists make some thousand invoices daily; passed through the Ledger Office, where about 90,000 customers' accounts are kept, and finally into the Order Filing Room, where every customer has a bundle to himself arranged on shelves on the principle of a library.

At the close of the visit His Majesty expressed the pleasure the visit had been, enabling them to see the important work the firm were doing in helping to keep up the food supply of the country.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

VARIETIES OF MULBERRY.—On p. 100 I expressed the opinion that there were varieties of Mulberry that were superior to others. I have since consulted Colonel Algernon Durand's work on *The Making of a Frontier*, and he states distinctly with respect to this fruit that there are quite superior varieties to be met with at Hunza Nagar. One in particular was called "Shaktut," "the King Mulberry," a large, luscious, purple fruit. "The very dogs feed on them," the author states. I do not in any sense mean to imply that we have not got this variety in this country, but I do think there are inferior sorts in cultivation. Colonel Durand also remarks upon a most superior Muscat Grape, and one that was "reserved for the royal family." This was at Chitral, and the Grape in question was said to have been imported from Central Asia. *J. Hudson.*

JERUSALEM ARTICHOKE.—On p. 126 it is stated that the name Jerusalem applied to an Artichoke "is considered a corruption of the Italian Girasole." Speaking for myself, I disbelieve profoundly in this derivation. I doubt if any evidence can be produced that Italians have ever called this vegetable "Girasole." I think it much more probable that Jerusalem Artichoke stands for a false Artichoke, or a vegetable resembling an Artichoke, on the analogy of "Jerusalem pony," which was an old-fashioned slang name for a donkey. Similarly, the word "Horse Chestnut" is used for a nut superficially resembling a Chestnut. Of course, if historical evidence can really be produced that this Canadian tuber was introduced originally into England from Italy under the name Girasole Artiocco I should have to reconsider my opinion, but until that is produced I shall remain a "doubting Thomas." *Vicary Gibbs.*

UNDESIRABLE APPLES.—A variety of Apple unfavourably mentioned by Mr. Molyneux on p. 66—Duchess's Favourite—is a far better Apple in the Midlands than Worcester Pear

main, and ripens at the same time. Scarlet Nonpareil is of excellent flavour in March and April if well grown and ripened, and continues the season after Cox's Orange Pippin is finished. Red Astrachan is the best in flavour of the very early varieties in this district, but should be eaten directly it comes from the tree. Bess Pool is chiefly valuable in districts liable to late frosts in spring, as it is one of the last to open its flowers. [illegible] Kent would hesitate to [illegible] Lane's Prince Albert variety. W. H. G. [illegible] Worcester. H. J. [illegible] Norfolk.

Feeding Pigs from Small Gardens.—[illegible] at the present time [illegible] to [illegible] extent as I [illegible] figs [illegible] J. F. [illegible] orders [illegible] W. [illegible] Jerusalem [illegible] potatoes [illegible] unit for [illegible] J. F. [illegible] buttermilk [illegible] products be obtained [illegible] garden. H. [illegible] grains. Peas, Oats and Maize. W. [illegible] from [illegible] the size of [illegible] acres. I have not seen any of Mays two main mouths, and as for brewers' grains [illegible] J. F. If I had written this article in pre-war times I could have given [illegible] but I feel bold out since [illegible] of [illegible] of small gardens at the present time I [illegible] will be most disappointed. F. W. Harvey.

Early-flowering Shrubs.—The [illegible] weather experienced [illegible] notice the effect [illegible] Forsythias, 10 to 12 feet [illegible] through, literally [illegible] Never before have I seen them so perfect, beautiful. Pears [illegible] profusion [illegible] and, judging by the amount of buds, [illegible] fine. Ribes at various seasons are gorgeous, whilst Magnolia conspicua and Wyandotte [illegible] opening its flower buds, and will soon be a grand sight, provided frost does not occur before they are developed. R. H. Lemp, Mill Inn, Hoar Gardens, Bath hire.

Hippeastrum reticulatum.—On p. 129 mention is made of hybrids of Hippeastrum reticulatum. In the eighties of the last century more than one hybrid of this class was brought prominently forward. It was claimed for them that, inheriting the late summer or autumn flowering quality of H. reticulatum, they would greatly prolong the flowering season of hybrid Hippeastrums. One of the best known was Mr. Garfield, raised in the then prominent nursery of Mr. B. S. Williams, of Holloway. The hybrid was said to have been obtained by the intercrossing of H. reticulatum and a garden form. In flower on October 11, 1881, the plant was awarded a First-class Certificate by the Royal Horticultural Society. Messrs. Veitch, of Chelsea, obtained a First-class Certificate for the variety Autumn Beauty in 1883, and for Autumn Glories in 1885, both raised from H. reticulatum. All of these plants showed strongly the influence of H. reticulatum. The two first-above mentioned, some hybrids of the same section were, I believe, raised by Mr. J. O'Brien, when in Messrs. Henderson's nursery at Maida Hill. One of the best known of these was O'Brieni. It is questionable if any of them could be obtained at the present time. It may be noted that when these different varieties were raised the genus was universally referred to as Amaryllis. W. T.

CROPS AND STOCK ON THE HOME FARM.

Cabbage for Cattle.

Another season, if that were necessary, has proved the great value of Cabbage for cows, pigs, sheep, and poultry. No other green crop can produce so much food for cattle on the same area. If early and late Drumhead varieties are sown early in April, the former will be ready for use in September and the late variety from November to [illegible]. The heads kept quite good [illegible] succession of good food for [illegible] At this point in favour of a good [illegible] [illegible] it to sheep is that [illegible] [illegible] Cattle, Sheep, and Pigs [illegible] the [illegible] especially if fed [illegible] should be [illegible] without [illegible] [illegible] [illegible]

MARKETS.

COVENT GARDEN, March —

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate not only from day to day, but occasionally several times in one day.—Eds.

Plants in Pots, &c.: Average Wholesale Prices.

	s. d.	s. d.
Ali 48's, per doz.	24 0	36 0
Aralias	12 0	18 0
Araucaria excelsa	12 0	18 0
Asparagus plumosus	10 0	12 0
— Sprengeri	9 0	10 0
Aspidistra, green	36 0	42 0
Begonia, tuberous	18 0	24 0
Cyclamens		21 0

Smilax, per bun. of 6 trails	2 0	2 6

REMARKS. Large quantities of cut flowers will be required this week for the Easter festivities. White flowers will be the chief attraction, and high prices are anticipated for the best blooms of Richardias (Arums), Lilium longiflorum white Roses, Carnations, white Tulips, and Lily-of-the-Valley. Coloured varieties will also advance in price. Home-grown Daffodils, which are now arriving in good condition, should be sufficient for the demand. Roses and Carnations are arriving in excellent condition, but the cooler we other may check the supplies before the week-end. Amongst the French flowers, White Stock, Star of Bethlehem (Allium), and coloured Anemones should sell freely.

Oranges, per case	100 0	120 0
— strawberries forced per lb.		0 20 0
Walnuts kiln dried, per cwt	100 0	110 0

REMARKS. Supplies of English Apples are decreasing daily. Prices likewise are on offer, but are unchanged. Gros Colmar Grapes are still in the market, but supplies are very small. Early arrivals of Almeria (Spanish) Grapes are meeting ready sale. English and Continental Strawberries are also coming forward, and supplies of forced Strawberries are much more plentiful, and supplies of Vegetable Marrows are increasing. Fair quantities of Cucumbers are on offer, but supplies of Mushrooms are short. Chicory and Cauliflowers are fairly plentiful, and Asparagus is also in evidence. E. H. R.

Covent Garden Market, March 27, 1918.

Obituary.

W. DANIELS—We regret to announce the death of Mr W. Daniels, Park Superintendent and Cemetery Registrar, Dewsbury. He died on the 15th inst., aged 69 years. Mr Daniels had been superintendent of Dewsbury Park for 13 years.

W. JAMES EWART. We regret to announce the death of Mr W. J. Ewart, a well-known Scottish gardener. Mr Ewart was gardener to Miss Dawson at Powfoulis, Falkirk, for over thirty years, and was an excellent all-round gardener and a successful grower of Orchids, particularly those of the cool section. Deceased, who was 72 years of age, has left a widow, two daughters, and two sons. A third son was killed in action at Loos while serving as a sergeant in the Cameron Highlanders.

RONALD BIRKINSHAW.—We regret to announce the death of Mr. Ronald Birkinshaw, eldest son of Mr T. W. Birkinshaw, gardener at Caldecote Towers, Bushey Heath. Deceased was a signalman in the Navy, and his ship was sunk recently, his name being afterwards conveyed to his relatives as among those lost. Before the war he was employed in the gardens at Hatley Park, Hickleton Hall, Hutton Hall, and Mote Park.

GARDENING APPOINTMENT.

Mr G. W. Baxter, for the past two years Gardener to A. A. EMBIRICOS, Esq., Hautetville, Harrietsham, Kent, is Gardener to W. BURGESS, Esq., The Lodge, Farnham Royal, Slough, Buckinghamshire.

SAFFRON WALDEN, BISHOP STORTFORD AND DISTRICT FARMERS' AGRICULTURAL ASSOCIATION.—At the ninth annual meeting of this Association, the report of the committee of management showed that it is in a flourishing condition, with a membership of 338 and a turnover for the year of £55,257, on a paid up capital of only £88. Mr A. S. Corbett, General Director of the Agricultural Organisation Society, to which the association is affiliated, congratulated the members upon the results of the year's working, and said the principle of co-operation among farmers was spreading

ENQUIRY.

WILL some readers kindly advise as to the best variety of trout for an inland lake of about 3 acres? There is a fair supply of fresh running water. About what number of fry and one-year-olds would be a good stock for this area of water? Also when is the best time to place the fish in the lake? Where can a reliable supply be obtained near to the district of Godstone, in Surrey? Any other information would be acceptable. *J. E.*

ANSWERS TO CORRESPONDENTS.

APPLES: *A. L. S.* The Apple known as French Russet is not very commonly grown in Leicestershire, but the old Royal Russet, which is very similar, does well in that county. There are, however, many better varieties of Apples than either of these Russets, and you would do well, especially if your orchard space is limited, to choose Apples which would yield a more remunerative return.

CAMELLIAS AND GENISTAS: *C. M. L.* Both these plants may be propagated from cuttings inserted in September. Cuttings of Genistas should be placed in a gentle bottom-heat until they are rooted, which may not be until the following spring. In the case of Camellias, choose well-ripened growths without flower-buds, insert the cuttings in sandy soil, and place the cutting-boxes or pans in a cold frame until the following February, when they should be introduced into gentle bottom-heat. The shoots will soon form roots in moderate warmth. Care must be taken to protect the cuttings from frost during the winter. Genistas may, if desired, be treated in the same manner as Camellias, but are better placed direct in bottom-heat. Use clean silver sand or very sandy soil for the soil in which the cuttings of both plants are inserted.

DAMPING OFF: *C. F.* It is true that an excessive amount of atmospheric moisture is the commonest cause of damping off in seedlings, but this condition can also be brought about by keeping the soil too moist, or by allowing the seedlings to grow too thickly together. Occasionally the seedlings fall over as a result of wire-worm or eel worm at the roots; you should examine your seedlings and make sure that they are not attacked in this way. We would advise you to keep the soil drier, and to examine the pans each day, remove any seedlings which have damped, and sprinkle a little wood-ash and charcoal over the vacant space. Keep the house well ventilated; a high temperature is not alone sufficient to keep the atmosphere dry. With reference to your second question, you should apply to the makers, viz, the Molassine Company, Ltd., 28, Mark Lane, London, E.C. 3.

NAMES OF FRUITS: *J. T.* Winter Greening (syn. French Crab)—*H. K.* Sturmer Pippin.

TOMATOS: *M. W.* The Tomato leaves are affected by disease, and they have also the appearance of having been attacked by aphides. Spray the plants with liver of sulphur in the proportion of half an ounce to 2 gallons of rain-water, and add a large tablespoonful of soft soap, mixing the whole well together. Attend carefully to the ventilation of the house, for the plants need plenty of fresh air; a moist, stagnant atmosphere is unsuited to the Tomato, and favours the spread of disease.

WATERING PEACH TREES: "*In Doubt*," *Dublin.* Peach trees should be well watered just before they come into bloom; this watering will generally carry them over the flowering period, but on no account should the roots be allowed to suffer from drought even when the trees are in flower. Fork the borders lightly in which old Peach trees are planted, apply a dressing of artificial manure, and water the soil copiously. It is not absolutely necessary to pollinate the flowers to obtain a good set of fruit; much depends on the weather, but best results generally follow this practice

NOTES FROM KEW.—IV.*

THE Kew season opens at Easter, when, given reasonable weather in March, there is certain to be a feast of flowers for the crowds that visit the gardens. The average number of visitors to the gardens since a charge for admission was instituted is less than one-tenth of what it was in pre-war times. The numbers on last Good Friday, Saturday, Easter Sunday and Monday were: Friday, 3,696; Saturday (a wet day), 264; Sunday, 1,572; Monday, 10,650. For comparison I give the numbers recorded for the same days in 1914: Friday, 62,700; Saturday, 21,800; Sunday, 68,590; Monday (Bank Holiday), 147,765. Although a great falling off is revealed by these figures, it speaks well for Kew and for our people that so many came to see the gardens with the clouds of war hanging heavier than ever.

The allotment workers digging their plots on the green in front of the main entrance to the gardens on Good Friday were a surprise to many visitors. Kew Green is more stone gravel and sand than clod; still, no stone, no clod must remain unturned where good can be got out of it. Cabbages and Potatos do well on maiden soil, though poor, therefore the well-to-do Kew folk who, coats off, have tackled Kew Green need not feel that they are working in vain.

Further indications of the same kind inside the gardens are the ploughed up lawn in front of the Palace, where Potatos will be planted next week, and the empty flower beds, which formerly were filled with Tulips, Daffodils, Hyacinths, and other spring flowers, and now waiting to be planted with vegetables. Everywhere else Kew presents much the same features as it did in pre-war Easters. In No. 1 house, near the main entrance, the Aroids are looking little the worse, although visitors are not permitted to see them. The big tree of Amherstia nobilis never promised better for a display of flowers next month, and a good number of Anthuriums are in bloom. The Belladonnas in the border in front of the house are well advanced in leaf growth. To the left, in the enclosure where the historical Corsican Pine stands, the great expanse of Daffodils is rapidly approaching perfection, and the double-flowered red Peaches and groups of Forsythias in the shrubberies are good to see.

The most beautiful flowering tree in Kew at the present time is the Japanese Prunus subhirtella. It is so elegant, its branches evenly disposed, yet in no sense stiff or formal, and its pale pink flowers, almost white in the distance, are delightful. This is a tree for the villa garden as much as for the park, and it ought to become a rival in the affections of the people with Laburnums, Lilac, Almond and Hawthorn. There are many trees of this Prunus scattered over Kew, there is a particularly fine group of it south of the Palace lawn, with double red and white Peaches for companions. The Birches, with their white, brown and blackish trunks, are worth attention, the Kew collection being a particularly good one, and most of the trees are of fair size. The Elms also are worth inspection, some of them, particularly Ulmus montana vegeta, the Huntingdon Elm, and Wheatleyi, Wheatley's Elm, are far better than the English and Scottish Elms as trees for parks or roads. Groups of flowering shrubs growing among the collections of trees are a noteworthy feature at Kew. Berberis, Broom, Forsythia, Spiraea, Lonicera, Magnolia, Philadelphus, Ribes, and others have been planted in masses here and there for decorative effect and they are quite a success.

The Rhododendrons in the Dell looked plump and happy on Sunday after the drenching rain of the previous day. Some of the early ones were in flower, R. Fargesii, strigillosum barbatum, campanulatum, niveum, Davies' Early White, Handsworth Early Red, Rosa Mundi, The Countess, Luscombei (a grand bush, covered with bloom, and a number of smaller ones, a yard or so high, equally floriferous, proving the merits of this hybrid); Altaclarense, an old bush, laden with dark red flowers; Smithii album, a white arboreum cross, also old; and several big veteran early Arboreum crosses, red flowered and gay, but nameless. The best of a set of hardy varieties obtained from Messrs. Seidel, Dresden, about ten years ago, is one named Professor D. Reichenbach, but I am afraid it would not stand a chance against the Waterer class. England stands a long way ahead of all other countries in the breeding of Rhododendrons. Camellias in full flower in the Dell are puzzling to visitors, who are as surprised to find them growing and flowering in the open air here as they would be to find parrots in the woods.

There are jays and pheasants in the woods at Kew, and hares have been shot there recently. Birds of many kinds are numerous, especially blackbirds, and they are as destructive as monkeys, or the grey squirrels which have taken possession of Kew as rats do of a barn where poison, traps, and the gun are not used. However, like Lysander Pratt, we can find good in bad and bad in good, and the squirrels, like the geese and ducks, are a source of amusement to some visitors; the blackbird's singing charms most people, and hares and pheasants have in these times a real value. For his size, the tit-mouse does a big lot of mischief in the garden. He pecks holes in the Rhododendron flowers to get at the honey secreted at the base, and he prefers the honey of the red-flowered sorts to all others.

Bamboos at Kew no longer excite the experts, who appear to have learnt all they wish to know about them. It is to be feared that Bamboos are untidy plants, looking decidedly dishevelled in early summer, which is intolerable in the well groomed gardens. They show up best in winter, and a good quartet of them is nitida, fastuosa, which is 15 feet high at Kew, nigra, and japonica, or Metake, as it is still called in the nurseries. Nitida is a most elegant plant, quite unlike anything else, its clusters of bluish, quill-like stems supporting a canopy of thin, graceful foliage, being admirable. The four sorts named stand the weather better than any others at Kew.

The Azalea garden is worth visiting now if only to see the Magnolias. M. conspicua, Soulangeana, and stellata, are already in flower, and the others will soon follow. Speaking of Magnolias, one cannot but say specially nice things of stellata, which at Kew is a champion shrub. There are large beds of it on several of the lawns, it is plentiful in the shrub borders, and it is one of the very best forcing plants I know. The weather often spoils the effect, frost turning its snow-white flowers brown, and heavy rain or strong wind pounding most of the beauty out of them. All the same, it is a glorious, early flowering shrub.

In the garden round King William's Temple are the Chinese Rhododendrons. Few are in bloom: lutescens, an elegant, twiggy, small-leaved shrub with cowslip-yellow, Azalea-like flowers; Keiskei, a yellow-flowered, prostrate little plant, just the thing for a rockery; Fargesii, with crimson buds, and pink, open flowers; adenopodium, a good pink, with felted leaves; rubiginosum, pink, with big red anthers; racemosum, and intricatum (see fig. 65). My boy called the last-named "blue Heather." It is a great catch from the Far East; some good judges declare it is the pick of the whole of the Chinese Rhododendrons so far. Decorum looks very promising, its fat buds holding back wisely till the weather is safer, its fellow countryman, adenopodium, having been spoilt by frost through being earlier. Other noteworthy Rhododendrons flower

*Previous articles appeared in the issues of January 19, February 9, and March 9.

ng in the same part of the gardens are dilatatum, a showy plant of the Swamp Honeysuckle type; fulgens, and Metternichii. Near by in the same bed as the Witch Hazels are several bushes of Corylopsis Willmottiae bearing yellow, Hazel-like tassels. It is probably a good border shrub for this country.

Among the Spiraeas, Thunbergii and arguta are the only two species in flower, and there is nothing yet to catch the eye among the Leguminosae. Osmanthus Delavayi, an evergreen with small, ovate, dark green leaves and numerous branchlets, each bearing a little cluster of snow-white, very fragrant flowers, is happy against a south wall, though it is probably quite hardy

The plants in the rock garden are coming on fast. Frost has not done any appreciable harm, and the rain last week has made the plants generally wake up and get to business. There are good groups in flower of Primulas cashmeriana, denticulata, and its two varieties superba and alba, rosea, chumanthia, Auricula (type) frondosa, and the blue and yellow forms of the common Primrose. Chionodoxas Lucilae and sardensis are now almost weeds here, and the ground in places is blue with their flowers a week or two ago. Anemone Pulsatilla clothes a slope at the south end, and the white variety occupies a "pocket" lower down, with the yellow Bungeana near by. These are now in full bloom, and

FIG. 65.—RHODODENDRON INTRICATUM: FLOWERS PALE LILAC (NAT. SIZE.)

(See p. 143.)

Magnolia Kobus is also flowering freely against a wall, with a good crimson Cydonia japonica and the double-flowered Prunus triloba for its companions. In a villa garden close to the Victoria Gate a crimson Double Peach and Magnolia conspicua show that Kew has some local influence, but it really is surprising that Kew does not exercise more on gardens generally, seeing how easy it is for the thousands of visitors to become informed as to what plants will grow and are to be obtained from nurserymen. Is it that they are satisfied with the same old beef-and-beer and bread-and cheese plants in their own gardens, and come to Kew for the same reason as they go to the Zoo?

the rare A. obtusiloba petiolis, from Burma, is in bud. Saxifraga hirsuta, formerly called Stracheyi, is as good this spring as ever it has been at Kew, and the true Stracheyi is also to be seen for comparison. Omphalodes verna, both blue and white, is happy under the shade of a Yew, a similar position agreeing with Anchusa myosotidiflora. A short stemmed, big headed Aster-like plant, Townshendia Wilcoxiana, from N. America, ought to find favour with rock gardeners, and Corydalis tuberosa alba is another plant with distinct claims. A group of Bulbocodium citrinum, perhaps the pick of the hoop petticoat Daffodils as a rockery plant, is one of the best pictures in the rock garden. If there is a better it is the great patches of Erica carnea at the north entrance to the rockery, but we must not call this a rock plant.

THE COLLECTIONS INDOORS.

Proceeding to the houses, we may begin with the Alpine House, where there are many choice gems in bloom. For colour, Primula Mrs. H. J. Wilson, a viscosa or hirsuta cross, is an easy first, others of the same breed being less bright. That wonderful parasite Phelypaea foliata (see fig. 66) is in bloom. It flowered magnificently and for the first time at Kew in May, 1914, standing up on the border at the back of the rockery like a bunch of bright scarlet Gloxinia flowers springing from a rosette of the feathery leaves of Centaurea dealbata, the host plant. Seeds of host and parasite are sown together, and the Centaurea is then kept going till the Phelypaea springs up two years later. Its home is the Crimea and Caucasus, and seeds of it may sometimes be obtained from the Tiflis Botanic Garden.

In the Succulent House (No. 5) various Aloes are in bloom; the tree of Diospyros Kaki promises to have a big crop of fruit this season; Asparagus declinatus hanging round a high pillar is the perfection of elegance; and two other climbers, Petrea volubilis and Juanulloa aurantiaca, the former against the roof, the latter trained up a pillar, are worth seeing. This house has felt the war worst of all. Some things have had to go short, and the succulents have gone shortest. The consolation is that they will get over it.

No. 4, the people's conservatory, is quite a flower show. Hard wooded plants are well represented; there is a big group of well-bred Hippeastrums; many specimen plants of Eupatorium Ruellia, with big heads of blue-purple flowers; Primula sylvicola, which is only P. sinomollis with a second name, P. kewensis and its parent verticillata, P. obconica and P. malacoides are in fine floral array; Arctotis aureola, a glorified Marigold; big bushes of Impatiens, Eranthemum pulchellum, Prostanthera rotundifolia, a grand lot of Begonia manicata, the merits of which as a winter-flowering plant are little known, because the plant is generally starved; Isolomas, a yard high and well flowered, are the most conspicuous of the show things in this house.

Plants in the T Range are still generally in their winter sleep, so I mention only a few this month: Clerodendron myrmecophilum, with erect racemes of orange-red flowers; a hybrid Columnea which bears further testimony to the merits of this genus under the operations of the breeder; Streptocarpus Holsteri, which is no more a Streptocarpus than a robin is a nightingale, whatever the systematists may say; Begonia venosa, remarkable for its large, ear-shaped, frosted leaves and very conspicuous membranous, strong-nerved, inflated stipules, which sheathe the stem as a young Bamboo culm is sheathed; the white flowers, on long, reddish, erect peduncles, are just ordinary.

When mentioning the Clivias in the Temperate House last month, where they continue to be a great attraction, I remarked that more variety of colour ought to have been the outcome of the efforts made to improve C. miniata. I might have mentioned also the cream-yellow flowered Clivia which was introduced from Zululand to Kew about twenty years ago and was noted by me in *Gard. Chron.*, April 15, 1899, p. 223. It has flourished at Kew ever since, and seedlings raised there have flowered and proved true to type. All attempts to cross it with the darker-coloured varieties have failed. There is a fine example of it in flower in the Begonia House now, and I believe it to be a distinct species, differing from C. miniata in not developing offsets, the more crowded umbel of flowers, and in the perianth being much shorter and the segments more reflexed at the tip. There is also the colour difference. Properly grown, this distinct-coloured Clivia is a

first-rate garden plant. It likes more warmth than miniata, stove treatment suiting it perfectly. Breeders of Clivias ought to try their luck at crossing it with the other species, for it does not follow from our failure at Kew that the cross cannot be accomplished: indeed, we have not given up hopes yet, for the attempt has been made again this year.

Mention must be made of a few of the Orchids in bloom. Pleione yunnanense is flowering when all the other species are in full growth: Liparis nuda ntha, which Kew owes to Mr Elwes, is the best of its genus, which is not saying much, perhaps; Cymorchis kewensis is uncommon-looking and is not unattractive. Other interesting Orchids are the blue Dendrobium Victoria-Regina, the fringed yellow D. Hargravianum, the madder-yellow D. Thwaitesii, several good spikes of Renanthera Imschootiana, Cymbidium eburneum with eight perfect flowers, a fine example of Cypripedium Parishii, and a new good Odontioda. Brassia Crawfurdii, in the Palm House, continues to astonish visitors who call it a kind of Rhododendron, taking it only the big bunches of flowers and not the true foliage.

In the Temperate House the Himalayan Rhododendrons and the hybrids raised from them are the great feature. At present the hybrids have it, more especially Mr. G. Sidoli Fulmonti. His Glory of Penjerrick, Girls' Triumph, and Beauty of Tremough are three kings of their kind. He has lately added a fourth named Ernest Gill, after his soldier son who had he been Sir William Roberts himself, could not have asked for a better floral compliment. In a corner of the rock used Lysichitum camtschatcense, or the yellow-spathed Arum from North America, is again in flower. It is also flowering in the swamp outside, proving both hardiness and adaptability in a plant which stands well among the Aroids for showiness. In the Mexican end of this house Bruntelsias are the best shrubs in flower. They are planted out, and they do not mind shade. The true Howea Belmoreana, lately figured in the *Botanical Magazine*, is still in bloom: it is quite distinct from H. Fosteriana with which it had formerly been confused, probably owing to the seeds of both having been collected together in those early days on Lord Howe's Island and sent here as Kentia seed simply. I have frequently been assured that the two plants were only varieties of one species as both came up from the same lot of seeds. W. W.

ORCHID NOTES AND GLEANINGS.

LAELIO-CATTLEYA PLUTO.

A flower of this pretty new hybrid raised between L.-C. Dominiana (L. purpurata × C. Dowiana) and L.-C. Firebrand (C. Trianæ × L.-C. Ingbirdiensis) is sent by Baron Bich, Esq., Ashtead Park, Surrey (Orchid grower, Mr. W. H. White). The bloom is more than 5 inches across and the petals nearly 2 inches wide. Both the sepals and petals are old-gold colour with a tinge of rose, the petals having a dense spotting of reddish-rose. The neatly formed lip is purplish-mauve with thin dark lines on a yellowish ground at the base. The fleshy column is white, and the pollinia is scarcely distinguishable from true Cattleya, there being three species of Cattleya and two of Laelia in the parentage of the cross. As usual, however, the orange fire of L. cinnabarina through L.-C. Ingbirdiensis takes possession of the colour.

CYPRIPEDIUM TOM WORSLEY.

T. Worsley, Esq., Carter Place, Haslingden, sends a flower of this handsome hybrid between C. Actæus langleyensis (insigne Sanderæ × Leeanum) and C. Helen II. (insigne Chantinii × bellatulum), which is now fully matured and displays a marked improvement over the first flower of 1916. Two features are specially noticeable, viz., the breadth of petals inherited through C. bellatulum, and the clear, pale-yellow ground colour following the C. insigne Sanderæ in C. Actæus langleyensis. The dorsal sepal is white with a pale yellow base and lines of oblong purple blotches, and the petals, which are each 2½ inches long and 1½ inch wide, Primrose-yellow, changing to cream colour towards the tips, and having slight dotted lines of purple. The lip and staminode are light yellow, the latter having an orange-coloured keel in the centre.

FIG. 126.—NOTES FROM KEW.—PHILYDRUM FLUVIATILE, A SCARLET-FLOWERED PARASITE, GROWING ON CONVOLVULUS FLAGELLIFORME. (See p. 134.)

THE MARKET FRUIT GARDEN.

It is seldom noted that we are favoured with an early and sunny March as the month that has just passed away. The record of my private station extends back for eighteen years, and during that period no March has equalled the past month in meteorological advantages. The great majority of the days were sunny, and some were quite warm, while up to the night of the 27th rain had fallen on only five days, amounting to no more than 0.26 inch. For the 28th 0.32 inch were measured, followed by 0.42 inch on the 30th, and the totals for the month were only 8 rain days, and a total fall of 1.02 inch. Frost, 2 to 5 degrees, was registered on the screen only four times. The wind was very cold at times, even on sunny days, but this is almost invariably the case in March. The nearest approach to the favourable conditions of the latest March was in 1900, at least in dryness, for in the March of that year rain fell on only five days, amounting to no more than 0.60 inch. That month, however, was a very cold one, and there was hardly any sunshine. The rain of the end of last month was needed to soften clods in fields, and to bring up seed in fields and gardens. For all kinds of work on the land—ploughing, sowing, planting Potatos, cultivating orchards, and hoeing, the conditions have been excellent, and they cannot fail to have a marked effect upon the food supply of the country, while they have enabled fruit growers who have had sufficient labour to transform orchards from an exceptionally grassy and weedy condition to one of uncommon cleanness for the time of year.

PROGRESS OF VEGETATION.

Previous to March the season seemed likely to be a somewhat backward one in the development of fruit and flowers. Even now that the past sunny month has promoted advance greatly, the chilly nights have checked the effect of the sunshine, and my chronicles show many years of rather less development in the latter part of March than has been seen this season.

RECORD PRICES FOR APPLES.

In the latter part of March Bramley's Seedling and Newton Wonder were quoted in London up to 30s. per bushel, as the top price for very choice lots. This, I believe, is a "record"

wholesale price for cooking Apples. The price named for Bramley's was given in the price list of the Board of Agriculture for the week ended on Wednesday, March 27. The prices quoted in this list are usually lower than those of trade papers, and often below what I have obtained.

THE SPRAYING SEASON.

The fruit grower's tribulation is beginning, if it was not begun earlier in the form of winter spraying, which I missed for the first time this season. There were several reasons for missing it. In the first place birds have not touched a fruit bud on Plums, so far as I have seen in many careful inspections up to the last week of March, by which time the blossom was on the point of opening, a stage in which it is not harmed by birds. In the next place, the only benefit of winter spraying observed by me is that of clearing moss off the trunks and branches of trees, and spraying in alternate years would suffice for that purpose. Then there were deterrents in the very high prices of spray-stuffs, the great rise in wages, and the scarcity of male labour. But now it is necessary to spray against injurious insects where these are noticed to have begun their work of injury. Experiments in the United States, in two seasons, proved that the only successful operation to control the aphis on Apples is that of spraying when the pest is found outside the unopened blossom buds, just showing in very compact form immediately after the bursting of the fruit buds. The statement in the report of the experiments is that the aphides are then outside the buds, waiting to obtain an entrance, so that they can be easily wetted by the spray-fluid and killed. Knowing from costly experience the futility of spraying after aphides have had time to curl the leaves, it was my intention to spray against them at once after finding any considerable number of them in a vulnerable position. But, whatever their disposition may be in the United States, they are not accommodating enough in my orchards to remain outside fruit buds a day after these have burst. At least, that is the case with the majority of them, and it does not answer to spray for the minority only. As soon as the tips of the blossom buds in their compact clusters show, as they do immediately after the bursting of the fruit buds which have enveloped the clusters, the aphides creep in among those tips, or between the embryo leaves encircling them, and are thus more or less protected against spray fluid. By the way, it would be a great advantage if all writers on fruit would distinguish between "fruit buds" and "blossom buds," limiting the former term to what may be termed the parent buds—the compact parent buds—and the latter to the clusters of buds which will become blossoms. Now, only in one piece of Worcester Pearmains were aphides found to any considerable extent outside unburst fruit buds, and then not in one out of ten buds. Where the fruit buds had burst it was necessary to pull apart the blossom buds, as a rule, to find aphides, and in the course of that operation suckers, thrips, and caterpillars were occasionally found. Therefore, if only for the destruction of aphides, it was deemed advantageous to wait a few days for the separation of the compact clusters of blossom buds, in order that the spray stuff could be made to penetrate well among the clusters. Moreover, this decision was all the more justified by the desire to kill aphides, suckers, thrips, and caterpillars, so far as possible, in one spraying. With respect to suckers that does not mean much, partly because these pests are such adepts in protecting themselves low down between the stalks of leaves and blossom buds, and partly because not half of them are hatched when it is desirable to act against an early attack of the aphis. In regard to caterpillars, however, in memory of the catastrophe of last season, when they destroyed millions of blossom trusses, I am even more anxious to kill them than to destroy aphides. Where any considerable number of caterpillars are found, arsenate of lead will be added to the aphis wash, to poison their food. It would be better, no doubt, to use the two separately, because arsenate of lead is best applied in a very fine spray, while aphis-wash should be applied profusely and forcibly. But the two operations could not be got half through before the opening of the blossom, and after the fall of the petals it would be too late to prevent a possible repetition of last year's misfortune. Arrangements have been made for commencing operations upon the earliest blossoming Apples on April 2, following upon others as they become fit. It is gratifying to report that extremely few caterpillars have been found at present, but this is no security against their appearance in great numbers later on, as it is early for the eggs to hatch. In many cases a hundred trusses of blossom buds have been examined with a lens without finding one of these enemies. The worst case was that of four out of fifty clusters having been found to contain a caterpillar. Further, it is to be mentioned that the proportions of trusses containing aphides, so far as they can be found in the compact clusters of blossom buds, are very small as a rule, while twenty to fifty trusses of some varieties of Apples have been examined without finding any pest. Mr. Theobald informs me that the aphides found by me, some of which were sent to him, all belong to the species *A. sorbi*, otherwise known as the rosy aphis, a leaf curler, and the most common of the aphides in this country. Thrips (*Euthrips pyri*) have been found in greater number than any other pest. They attack blossoms and fruitlets, injuring many and killing some. The fullest account of this pest I have seen is in Mr. Theobald's *Report on Economic Zoology for 1909-10*, published by Headley Brothers, Ashford, Kent. Observation has proved to me that many thrips are killed when profuse spraying is carried out against the aphis. *Southern Grower.*

FIG. 67.—"NOTES FROM KEW": LYSICHITUM CAMTSCHATCENSE FLOWERING IN THE TEMPERATE HOUSE (see p. 145).

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

CARROTS.—Make a sowing of Carrots in ground that has been well prepared some months in advance. This root crop needs a light, warm soil, which has been well manured. Sow the seed in drills made one foot apart for varieties having medium-sized roots, and 15 inches for the larger-rooted sorts. By making successional sowings good crops of small roots will be always available. Heavy ground should be lightened by the addition of wood ash, road scrapings, old potting soil, and similar materials. Varieties previously recommended should be sown for early use, whilst Scarlet Intermediate is the best sort for general purposes.

HERBS.—Mint, Tarragon, Sage, Thyme, Sweet and Pot Marjoram, and Sweet and Bush Basil, are the most useful herbs. Mint and Tarragon may be propagated easily by division; the others are readily increased from seeds sown this month on a warm border in drills made one foot apart. Thin the seedlings to one foot apart for transplanting permanently later, or they may be replanted when large enough to handle early in June.

RUNNER BEANS.—In gardens where means exist, 200 or 300 small pots may be sown with Runner Beans. These pot plants may be put out towards the end of May with very little check to growth. Last year much of the seed of Scarlet Runners did not ripen, and old seed will of necessity have to be sown this year. It will, therefore, be advisable to sow rather more thickly than usual. Sowing in the open should be deferred for a few weeks.

CELERIAC. This delicious root vegetable is not so extensively grown as its merits deserve. Seed should be sown forthwith in boxes filled with fine soil and germinated in gentle warmth. The raising, hardening, and pricking out the seedlings should be done as in the case of Celery, but instead of planting them in trenches they should be planted on the level in deeply-dug and well-manured ground. Where the soil is light in texture, or in dry seasons, the plants will need watering.

GLOBE ARTICHOKES.—Deep cultivation of the soil is necessary to secure the best results with Globe Artichokes, and much depends on the variety. Purple and Green Globe vary considerably; a good form of the latter is probably the best sort, and it is extensively grown. New beds should be formed every fourth or fifth year. Detach some of the strongest suckers from the old stems with roots attached to the buried stems, and plant them in ground that has been deeply trenched and heavily manured, or a better plan is to place a number of suckers singly in 7-inch pots, grow them in gentle heat until they are well rooted, and plant them when they are suitably hardened at a distance of 3 feet apart each way. Subsequent culture consists in mulching the roots, keeping the plants clean of weeds, decaying foliage and rubbish, and watering occasionally in dry weather. Remove the protective litter from old plants, apply a good dressing of rotted manure, and lightly fork the dung into the soil. To secure large Artichokes remove some of the flower-heads on the side shoots.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

CHRYSANTHEMUM.—Pot young Chrysanthemums as soon as they are ready for a shift, using a fairly substantial compost. A mixture of loam, leaf-mould, manure from a spent Mushroom-bed, wood ash, and coarse sand in proper proportions, is suitable for Chrysanthemums. For later potting a little bone meal or crushed bones may be added to the compost. All the plants may be shifted into cold frames, where with careful watering and ventilating, they will

do better than in warm houses. Recently potted plants should be kept in a close atmosphere for a day or two, and shaded from bright sun, but they should be accustomed to cooler conditions as soon as they have recovered from the check caused by disturbing the roots. Do not crowd the plants at any time, as this would favour the spread of rust disease. Spray the plants with an insecticide about once a fortnight.

CHIRONIA EXIFERA.—Chironia exifera is an exceedingly useful plant for decorative purposes during late summer and autumn, and is very easily cultivated. It may be propagated any time in the spring when cuttings are available. Insert the cuttings in pots or pans filled with a light sandy compost. Well water them in with tepid rain-water and place them under a handlight or a Cucumber or Melon house. When rooted transfer them to a light house having a medium temperature. Shift the cuttings into 3-inch pots when they have rooted well, using a compost consisting of loam, peat, leaf-mould and sand. Pots 5 inches in diameter are large enough for the final potting. Great care is necessary in affording water to the roots, for carelessness in this matter is often the cause of failure. Old plants may have their roots slightly reduced and be potted into receptacles one size larger than before.

BOUVARDIA.—If Bouvardias were treated as advised in a previous calendar plenty of young plants should now be ready for potting into 3½ inch pots filled with sandy soil. Grow the plants on in a house having a medium temperature. Pinch the young shoots two or three times during active growth to obtain dwarf, bushy specimens. As the weather becomes warmer Bouvardias should be gradually hardened off and placed in a cold frame. In view of the shortage of labour the plants should be planted out to ward the end of May, when danger of frost is past, on a well prepared border sheltered from rough winds.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN Bart., Gatton Park, Reigate.

DENDROBIUM.—Spring flowering Dendrobiums and particularly those of the Nobile section, are passing out of flower, and the necessary repotting or top dressing should be done as soon as roots develop from the bases of the young shoots. Ordinary flower pots form the most suitable receptacles, and the rooting medium should consist of a mixture of Osmunda fibre, or Al fibre, and fresh Sphagnum moss, cut into short portions, and a sprinkling of crushed crocks. The whole should be well incorporated together. Specimens that require repotting, after being taken from their pots, should have the compost shaken from the roots, and all useless pseudo bulbs removed, leaving only three or four behind each leading shoot. The pot should be just large enough to hold the plant comfortably, and filled to about one fourth its depth with clean crocks to ensure good drainage. Press the compost rather firmly, but not hard; when potted the base of the plant should be level with the rim of the pot. Tie the pseudo bulbs to strong, neat stakes to keep the plant secure in the pot. The surface of the soil may be covered with a layer of chopped Sphagnum moss at once, or later when the roots have grown freely, the latter being the better plan. After root disturbance water should be applied with extra care, or many of the new shoots will damp off. When the roots reach the edges of the pots the plants should be afforded liberal supplies of moisture until the new pseudo bulbs are fully developed. Newly potted plants should be shaded for a few hours during the middle of the day. Healthy specimens that have ample pot room, and with compost in a good condition, should have a little of the old materials removed from between the roots and replaced with new. All Dendrobiums of this section require a hot, moist atmosphere during their growing season, and are benefited by exposure to the early morning and late afternoon sun. During hot weather light sprayings overhead each afternoon will be beneficial. The old pseudo bulbs that have been removed may be propagated if an increase of the stock is desired, selecting those with dormant eyes that have not produced flowers. In preparing the pseudo bulbs for rooting, cut them to a single bud that has not flowered; make the cut close to the "eye" at the top end, leaving rather more of the stem at the bottom to insert in the compost. The cuttings may be placed in 4-inch pots half filled with drainage, putting a layer of Sphagnum moss over the crocks and fill to the rim with a mixture of finely chopped Sphagnum moss and coarse silver sand. Insert the cuttings in an upright position, and press them into the compost at a depth sufficient to hold them firm without covering the buds. They may be rooted in a warm propagating frame. Keep the materials on the dry side, and spray the young plants lightly on bright days. When the young shoots commence to develop roots shift them into small pots, using a similar compost to that advised for established plants.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

PELARGONIUM.—Plants of bedding Pelargoniums may, in most districts, be transferred to cold frames or cold shelters. Provided the plants have not been cobbled they will withstand a comparatively low temperature with a little protection. In shelters the covering need not be removed day nor night for ten days or so. In frames, on the contrary, the plants should be kept covered in the daytime only when cold winds lower the temperature. No water should be given until the weather is more genial; the shading is to keep the plants moist enough to meet their requirements. Many other bedding plants may be grown on in cold frames but not the very tender ones.

BIENNIALS.—Canterbury Bells and Sweet Williams are frequently not sown till it is too late to obtain good sized flowering plants, at least in the north. It is better to sow some time in this month, early or late, according to the locality. The plants will not develop so fast, but on the whole they will be much superior in every way. It is doubtful whether the old-fashioned method of sowing thinly broadcast is not to be preferred to sowing in drills in which the seedlings are apt to become drawn and weakened through not having attention when it is wanted, owing to pressure of other work.

DAHLIAS.—Old Dahlia roots may be divided as soon as sufficient growth has been made to enable this to be done, and planted at once, the buds to be 4 inches below the surface when planting is completed. The shoots will not appear above the ground until danger from frost is past, and the young shoots are considerably hardier than the growths of Potatos, which, it may be noted, are treated in much the same manner as advised for Dahlias. It is to their advantage, too, to be flowered earlier and are more floriferous than those produced from cuttings, and, of course, the labour expended on them is much less. Young plants should now, or shortly, be turned into cold frames and carefully watered for a time. Treated thus they will be more stocky than those grown on in a glasshouse or cold pit.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

HARDY FRUITING VINES.—The present month is the best time to prepare the border and to plant hardy Vines. An impression seems to exist that Grapes cannot be grown successfully out of doors in even the most favoured parts of this country. The site is all important as the keystone to success. Vines should be planted in a warm southern aspect, or one that tends to the west rather than to the east. No elaborate system of wiring or training need be adopted: all that is wanted are a few galvanised studs to secure the Vines for the time being, others being added as growth progresses. Give care and attention to the preparation of the border, as this is essential to obtain a good start. The border need not be of great extent for the first season or two. Three good barrowfuls of compost should be ample for every Vine that is planted. Take out the present soil to a depth of 2½ feet, make up the lower 6 inches with brickbats or old mortar rubble, putting some of the finer portions on the top. Then fill up firmly with the soil to within 6 inches of the top. On this proceed to plant the Vines after having carefully shaken the roots free of the soil and disentangled them. It is advisable to remove all the old soil by soaking the ball in water, after which it will be an easier matter to separate the roots. Spread the roots carefully and evenly in the upper 6 inches of the border, and fill up with first some of the finer portions of the mixture, and then with the ordinary compost. Make the soil firm, firing, and water it once or twice shortly after planting to settle it around the roots. As the Vines will probably not have been pruned, it will be safer to leave them as they are for the present. Eye-shoots should be disbudded later. Too many shoots should not be retained in the first year; two bold shoots and three or four laterals will be sufficient. The compost should be chiefly composed of the best yellow turfy loam obtainable. One-sixth of the three barrowfuls might be of well decomposed manure, and some sifted lime rubble should be added when on the dry side. The compost should be well mixed; it not very dry turn it once or twice more. A few varieties of Grape only are recommended for out-door cultivation. Of these Black Cluster, a hardy variety with blue black berries; Reine Olga, one that has frequently been shown, tawny red when ripe, and of Muscat flavour; Cambridge Botanic Garden, a black variety that ripens its berries early; and Sweet Water, usually called Dutch Sweetwater, also an early variety, with pale green berries and a thin skin.

FRUITS UNDER GLASS.

By W. J. GRIGG, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

POT VINES. When pot Vines are swelling their berries the roots require plenty of stimulants, both in liquid form and as top dressings. Weak liquid manure in a tepid state is an excellent stimulant for pot Vines; at the same time a change of fertiliser is advisable, and the liquid manure may be varied by soot water, guano, or a "concentrated fertiliser." When the Grapes are well past the stoning period the Vines may be forced a little more, but not by the use of extra fire heat at night, when the temperature should be kept below 70°, with a little air. It will be brought about by closing the house early in the afternoons and thus raising the temperature by sun heat, with plenty of atmospheric moisture. Ventilate the vinery with caution, admitting fresh air gradually, and never so as to cause a cold draught. Pinching the shoots should not be carried to extremes if the roots have penetrated the bed, and, as every leaf assists the fruit, good lateral growths should be tied out to secure an even balance of foliage over the trellis.

UNHEATED FRUIT HOUSES.—Orchard house trees in pots that are still out of doors should be placed under glass at once. They may be introduced into any unheated structures which will afford protection from late frosts. The house should be fully ventilated during the day, also at night when the weather is mild, to retard the flowering season as much as possible. Fumigate the trees before the flowers open, as usually dormant aphides are present on the buds, and directly the insects feel the effects of a little more warmth they become active and spread quickly over the trees.

MELONS.—If space is available for successional crops of Melons a good supply of young plants should be provided. Fill a large box with fermenting materials and place it in a warm pit. Sow a few seeds singly in small pots once a fortnight, and plunge the pots up to their rims in the hot bed material. Place the box near the roof glass to ensure the seedlings making sturdy growth. Early plants are well advanced, and as they are trained to the trellis will gain in strength daily. Remove all male blossoms up to the time the female blossoms are ready for fertilising. At this period the amount of moisture in the atmosphere and at the roots should be slightly decreased, but not unduly. When the fruits commence to swell more water may be given, and liquid manure may be used occasionally until the fruits have reached their full size. The night temperature should not fall below 70°, with a rise of 10° to 15° during the day. Increase the amount of ventilation gradually as the sun gains power.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER**, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENT FOR THE ENSUING WEEK.

TUESDAY, APRIL 9—
Roy. Hort. Soc. Coms. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 46.0.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday, April 4*, 10 a.m.: Bar. 29.7, temp., 50.5°. Weather Dull.

Grow more Potatos.

Gardeners who will take thought and ask themselves by what counter offensive they may seek to make good the ground recently won by the enemy will find the answer at the head of this article. The considerable area of ground which has been occupied by the Germans has involved a by no means negligible loss of foodstuffs both actual and potential. For it is evident that much of the ground over which the fighting has taken and is taking place was under cultivation, and might have yielded food for large numbers of men. To help to make these losses good every man who has land capable of being used for food production should resolve forthwith to place yet another piece of it under food crops, and above all under Potatos. Little more than a square yard of garden ground will, if put under this crop, yield enough food to supply—as measured in food units—the total requirements of one man for one day. It is not enough for gardeners to aim, as hereto fore, to produce supplies sufficient for the household. Every gardener ought to aim, and to aim most strenuously, to produce a surplus, so as to make a contribution toward the feeding of the urban population.

On the present rationing basis, the articles of food which are not yet rationed have to be utilised to supply some 1,100 calories out of the daily total of 3,500 required by an active and hard-working man. Of these articles, it may be possible to obtain sufficient fish and milk to make up about 500 of the 1,100 calories; but even so, there remain about 900 of the necessary calories which must be supplied by vegetables. Hence gardeners will have to produce considerably more vegetables even for household requirements, for to obtain the 900 calories just referred to a person will have to eat upwards of 2 lbs. of vegetables per day. This would seem at first sight a formidable task, but it has to be remembered that the Potato may be eaten in many different ways, and there is no doubt but that every household will have to use this article of diet much more freely than in the past. Therefore, cooks ought to be instructed—if they have not already learned—how to diversify the forms in which Potatos may be presented at table—at breakfast in the form of scones as well as at dinner in the form of "plain boiled."

Allowing 2 lbs. of Potatos per head, we arrive at the very considerable figure of 6½ cwt. per head per year, and therefore, the number in the household being known, the total requirements in Potatos are known. Allowing 10 tons to the acre as being a good garden yield—and it would be safer to allow 8 tons—we arrive at the conclusion that to supply sufficient Potatos to supplement the rations an area of from 5 to 6½ rods per person must be cultivated for household use alone; this without allowance for chats and diseased tubers, and without providing for a surplus for distribution among those who have no ground to cultivate. There is still time to bring fresh ground under cultivation, and there never was a time in our history when there was a clearer call to patriotic duty than that which summons every able-bodied man and woman to spend all the time they can spare or make to provide in the first place for their own needs, and in the second place to produce a surplus. No thinking man can doubt that our armies holding off the assaults of the enemy food will win the war. But not everyone realises so well as the gardener how much may be done in the way of home production of food. Therefore we appeal to every one of the fraternity who reads these lines to redouble his own efforts to increase the area of ground which he is cultivating and to make himself a missionary to promote by example and by precept the work of growing more food.

Facts are stubborn things, but ignorance is more stubborn. The facts of the situation are that, just as a motor-car requires a known amount of petrol to run a given distance at a certain rate, so a man requires a known amount of food to do the day's work. If he has not that amount, the work cannot be done. Of the food which man requires none can be produced more readily than the Potato; hence the appeal by the Prime Minister to grow more Potatos. An extra million tons is wanted. Most gardeners are already doing all that is possible; but there are still some who are living in a fool's paradise and pursuing the meticulous customs of peace-time gardening. To them especially we would appeal, and ask them to put aside all the unnecessary things of the garden and devote their whole energies to food production.

SALE OF BATSFORD PARK ESTATE.—It is reported that Lord REDESDALE is effecting a sale of a large portion of his property, amounting in all to about twenty thousand acres, and including the beautiful estate of Batsford, Moreton-in-Marsh. The late Lord REDESDALE, who died on August 17, 1916, was an enthusiastic horticulturist. Batsford was entirely his own creation. The mansion was constructed of stone obtained from a quarry on the estate, and the garden and grounds, including the celebrated wild garden and rock gardens, were created out of the green-pastured valleys and picturesque hills which formed the estate at the time of purchase. Bamboos are the chief feature of the gardens, but there is also a fine collection of trees and shrubs obtained from every part of the world.

FOOD EXHIBITION AT LEICESTER.—An exhibition to encourage Food Production, Food Economy, and the Preservation of Fruits and Vegetables has been held in the Museum, Leicester, during the past fortnight. The Ministry of Food was represented by two cookery experts, and the Food Production Department of the Board of Agriculture by Mr. V. BANKS, who staged a contribution of bottled and dried fruits and vegetables. Mr. LOWE, the curator of the Museum, showed specimens illustrating food values and the articles at present available as substitutes in place of those foods more generally used before the war. The Royal Horticultural Society filled a space of about 48 feet by 15 feet, illustrating garden tools, models of flat-digging, trenching, and Potato-planting, Haricot Beans grown at Wisley, models of vegetables, garden seeds, manures and fungicides, spraying machines, cases of models of insect pests, a collection of the newer Potatos, and homely methods of testing seed germination. They had also a model of a cellar or room fitted for the storing of roots and fruits, and a model of a cropped allotment. Three lectures on Food Production were given by Mr. CHAS. H. CURTIS.

MR. LEONARD SUTTON.—The sympathy of our readers will go out to Mr. LEONARD SUTTON, Deputy Mayor of Reading, and member of the firm of Messrs. SUTTON AND SONS, in the bereavement he has sustained in the death of his son, Lieutenant E. M. SUTTON, R.E., who was killed in action during the recent battles in France. Of his five sons who have joined H.M. forces, four have laid down their lives for their country.

APPOINTMENT.—Viscount GOSCHEN has been appointed Joint Parliamentary Secretary to the Board of Agriculture in succession to the Duke of MARLBOROUGH, resigned. He will represent the Department in the House of Lords. Lord GOSCHEN is the son of the first Lord GOSCHEN, Chancellor of the Exchequer from 1887 to 1892.

HOME-GROWN TIMBER.—The Board of Trade has issued a new Order as to maximum prices for home-grown timber, replacing the Order dated December 4, 1917. The principal changes made are in the prices for converted softwoods, but provision is also made for the certification of port or city sawmills by the Controller of Timber Supplies, to whom early application for the necessary forms should be made to obtain the benefits of the Order. All persons interested in home-grown timber should obtain a copy of the Order, which will shortly be on sale through the Stationery Office.

LEITH HILL, SURREY.—Wholesale destruction of the timber on Abinger Common, Leith Hill, is threatened, and an attempt is being made to secure its preservation. At the annual parish meeting held at Abinger on Saturday, the following resolution was proposed by Lord FARRER, seconded by Lady LUGARD, and carried unanimously:—"That this meeting of Abinger parish desires to call the attention of the Board of Agriculture to the proposed forcible felling of all timber on Abinger Common, Leith Hill, by the Timber Supply Department of the Board of Trade without consent of the owners or com-

meters, and expresses the hope that the Department will be able to save this spot of special interest and beauty from destruction."

PROTECTIVE POWER OF SNOW.—A correspondent, writing to *Symons's Meteorological Magazine*, says:—"The following observation shows the remarkable extent to which a covering of snow protects the ground and plant life from intense cold. About 6 p.m. on January 13 a minimum thermometer was placed on the ground in the centre of my lawn here, the temperature then being only a few degrees below freezing. Snow then fell to the depth of 1½ inch. At 11 p.m. the snow had ceased falling and it was a bright starlight night, and very cold. A second minimum thermometer was then placed on the top of the snow. No more snow fell in the night. In the morning, the two thermometers recorded the following minimum temperatures:—On the top of the snow, 2° below zero; under the snow, 24°, or a difference of 26°.

SUNFLOWER SEED.—It has been brought to the notice of the Food Production Department that growers are unable to obtain supplies of American Giant Sunflower seed at the prices mentioned in the notice recently issued by this Department, viz. 5d. per oz., 9d. per 2 ozs., or 1s. 5d. per 3 ozs. A considerable quantity of the sunflower seed has recently been released at a price which enables retail seedsmen to sell at these rates. The Department will be glad to supply retail seedsmen with the names of the wholesale firms from whom they can obtain supplies of this seed. The seeds of the Giant strain of Sunflower are much liked by cage birds and poultry.

THE GENUS EUCALYPTUS.—Eucalyptus *robusta* is the most widely diffused of all the Australian Eucalypts, being spread nearly all over the Australian continent, and occurring in all the States except Tasmania. In the XXXIII. and last part issued of his *Critical Revision* of the genus Mr. MAIDEN devotes ten pages of letterpress and three plates to the elucidation of this, which, after all considering its wide range, shows comparatively little variation, and has only two obscure synonyms. Its specific name is due to Sir JOSEPH BANKS, and, on the authority of R. H. CAMBAGE, "It is a common tree on the banks of many of the rivers and large creeks of North Queensland. It is often associated with Casuarina Cunninghamiana, and while usually of stable to ascend some distance, and descend much further down the streams, and this attribute or quality has enabled it to cross the continent from north to south and from east to west." Growing under the most favourable conditions Eucalyptus *robusta* is a handsome tree, 100 feet or more in height, with narrow, slender leaves sometimes nearly a foot in length, and small flowers with bearded lobes, followed by small "about 4 cubic inches in capacity." This Gum Tree is most widely known as the Pool Gum, though in some other districts bear this name in different distributed E. tereticornis.

VARIETIES OF BARLEY.—Mr. H. V. HARLAN's descriptive analysis* of one hundred and fifty-two varieties is useful to English students, for the only other original source of information, BEAVEN's *Botany of Barley*, being out of print, is not always accessible to them. The scheme of classification adopted by the author takes as its basis that cultivated varieties of the genus Hordeum are of one of four species, namely H. vulgare, intermedium, deficiens, and distichon, the two former including the six-rowed varieties, distichon the two-rowed forms, and deficiens the defectively two-rowed. H. vulgare is distinguished from intermedium by the fact that the lemmas of the florets are awned or hooded, whereas those of intermedium varieties are neither arched nor hooded. The author recognises 32 varieties, and diagnoses them by several characters in a key to varieties, and this is followed by a key to the numerous subvarieties. The bulletin concludes with a useful note on the identification of threshed material.

* *The Identification of Varieties of Barley.* By Harry V. Harlan. U.S. Dept. of Agric., Bull. No. 622.

PLANT NOTES.

JEFFERSONIA.

THE genus Jeffersonia is a member of the Berberidaceæ, and consists of only two species, one from North America, the other from Manchuria. They are both small, tufted perennials producing their flowers early in the spring before the leaves develope. Both are woodland plants and require a moist, shady position in rich light soil.

J. BINATA. J. DIPHYLLA.—Hab. North America.

ON INCREASED FOOD PRODUCTION.

CHINESE CABBAGE.

IN reply to Dr Durham (p. 91), I may state that my experience with this vegetable is recorded on p. 58. Whether the plants are Pe-tsai or Pak Choi I do not know; but he has a few seeds of the latter to spare I will grow the plants together this season, and state the results later. In the meantime, I have sent Dr Durham a little of the seed I grow as Celery Cabbage named by the Kew authorities last season, from their very rich foliage, as Shantung or Chinese Cabbage. I hope he will grow and determine for himself. Messrs. Ryder's state that the plant matures in eight weeks, and if sown in spring runs to seed. My experience was that the plant did not run to seed until after heads had been formed. I am curious to know how autumn-sown plants would act in spring, and hope to try again next autumn. I have made two trial sowings this month in West Surrey, both sowings are looking promising, notwithstanding that we are experiencing drought and sharp frosts. It has been suggested that this vegetable may prove a good field crop for cattle or sheep. *J. C.*

THE SOY BEAN.

In connection with the note by Mr. Lynch, on the Soy Bean, in the issue for January 26, 1918, p. 38, I should like to call your attention to an article in the *Botanical Journal* for March, p. 81, giving an account of experiments I have conducted during the past four years with a yellow-seeded variety of this Bean. In one particular the article is in error, it gives the number of

FIG. 160.—BUTTERS SAY TO BEE, "COLOUR OF FLOWERS RICH."

varieties known in China as four, distinguishing them by the colour of the seeds. As a matter of fact, there are many hundreds of varieties grown. The U.S.A. Department of Agriculture, at its experimental farm at Arlington, Virginia, last year held a trial of nearly 500 distinct varieties, which they had collected. I sent them seeds of my variety to test with theirs, in the hope of identifying it. They reported that it was an unnamed variety, probably from the vicinity of Harbin, a very prolific sort, not a pure strain, but one from which better yielding sorts might be obtained by selection.

I was successful in inoculating my plants grown at the Botanic Gardens last year with a culture of the Soya bacteria, received from America, and they bore a number of nodules on their roots This does away with any difficulty in future, since American experience shows that, to transfer the bacteria, it is only necessary to dust the seed, when sowing, with soil in which inoculated plants have been grown.

Mr. Lynch has sent me a few of his black Soya seeds to try, and as in his letter he states that he has grown this Bean at Cambridge for eight years, he is certainly entitled to the credit of first success in its acclimatisation. *J. L. North, Curator, Royal Botanic Society, Regent's Park.*

JERUSALEM ARTICHOKES

THE attention of allotment holders, gardeners, and small cultivators generally is drawn by the Food Production Department to the value of the Artichoke both for purposes of human food and for feeding to pigs.

Recent investigations by the Royal Society Food (War) Committee show that the Artichoke eaten in moderation is an excellent human food and that its food value as measured in calories is superior to that of the Potato. The composition of Artichokes and of Potatos is as follows:—

	Water.	Proteins.	Carbo hydrates.	Total Calories per lb.
Artichokes	79.5	2.6	16.7	365
Potatos	75.5	1.8	14.7	310

The Artichoke, moreover, gives large crops. An average yield from field cultivation is about 10 to 12 tons, but in gardens and allotments it should be considerably higher. Estimates of yield obtained by the Royal Society Food (War) Committee gives figures so high as 20 tons per acre on garden ground. Other advantages possessed by the Jerusalem Artichoke are that it is not subject to disease and will grow in almost any soil and situation provided there is an abundance of light and air. It succeeds best on a deep, friable, sandy soil. For planting, medium-sized tubers should be chosen or larger tubers may be cut into pieces, each with two or three eyes. The white tubered varieties are generally preferred to the pink as they are of a better shape. In the south, planting should be done during March or the beginning of April, but in late districts and in the North planting may be continued until the end of April. The tubers may be planted in shallow trenches or dibbled 4 to 5 inches deep, in soil which has been previously well worked. The usual distances at which to plant are 3 feet between the rows and 1 to 1½ foot between the sets. The planting should be closer in poor soils and wider in rich soils; 14 lbs. of tubers will plant a rod of ground. The only cultivation necessary is hoeing to keep down the weeds and the drawing of a little earth to the stem. The surface of the soil should be stirred during dry weather. Artichokes when fed to small pigs should be cooked, but sows will eat them raw. Under field cultivation and after the crop has been lifted pigs turned into the field will clean the ground by picking up the small tubers left in digging, and a further advantage of thus turning in pigs will be the increased fertility of the ground

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

EARLY-FLOWERING SHRUBS (see pp. 112, 130, 141).—In these gardens also Prunus Pissartii has been finer in flower this season than I have noticed it anywhere before. The tree usually flowers well with us, but this year it has surpassed itself. The typical P. cerasifera (the Myrobalan) from which P. Pissartii is derived has been equally fine, deserving the high praise bestowed on it by Mr. Wm. Robinson, "the showiest of all the Plums," an opinion that has always puzzled me. What is the reason of this exceptional flowering? Other flowering shrubs have started the season well, and most flowered freely last year. I associate the early and free flowering with hard, dry winters, another example of that much-debated mystery, "frost and the plants' awakening." *Harold Evans, Llanishen, Cardiff.*

FEEDING PIGS FROM SMALL GARDENS.—It is, indeed, hard lines for the useful pig, if special foods are so scarce as indicated by Mr. Molyneux on p. 141. I had no intention to say that the various foods I mentioned could be obtained from a 10-rod plot. I merely set myself to enumerate the various foods that a pig would eat and thrive upon, leaving readers to determine what is available in their respective districts. Small gardens in many country districts are by no means limited to 10 rods. I know from many correspondents during the past winter and previous ones that they have large gardens and plots of ground running up to half an acre or more. Some years ago I was talking to a clergyman in Berkshire, discussing the amount of produce he could get from his garden if he trenched a portion of it every year. He admitted the truth of my statements, but said that the amount of produce would far exceed his requirements. This would apply to many villa gardens, a large portion of which is laid out in lawns that give rise to a great deal of hard labour and return nothing. Ground that cannot be cultivated by the plough, being between streams, corners of fields, etc., are to be found in various parts of the country, and often lying waste. Such land would provide a large amount of produce for the household, pigs, and poultry. A fair quantity of Clover, Vetches, and Lucerne may often be obtained on waste ground on country farms and estates on which families may be located. In my younger days we cut sufficient green fodder on the banks of streams, ditch sides, and waste places on the farm to keep a cow and a horse from the time they were housed at night till put out on the pastures in the morning. I merely mention these things to show that there is often great waste of good green fodder than can be cut with the scythe and used for various domestic animals. *J. F.*

— I must take exception to the statement by *J. F.* on p. 116 that the "bottom of the small wooden house"—the sleeping compartment I take it being alone intended—"should be boarded to prevent the animals grubbing up the floor." For a like purpose countless numbers of pigs have been tortured by having their snout pierced by a ring or its equivalent, the object of both being equally fallacious and wrong. Pigs that exhibit unmistakable activity in rooting up the floor of the sty also demonstrate that they are improperly and insufficiently supplied with food. The remedy, therefore, is obvious. A pig that is given substantial meals sufficiently often and with regularity will invariably lie down afterwards. The animal that is always grubbing about is not fattening at the same time. In my youthful days my father kept pigs, and I had to take my share in looking after the animals. In only one instance was the floor of any sleeping compartment boarded, and that only partly so. Floor disturbance was, however, unknown, the pigs being fed well and regularly. From the time they were six weeks or so old, Barley meal scalded with the always cooked food was given, the whole being of gruel consistency. A frequent error made by cottagers in pig keeping is that of giving raw food. He will tell you he prefers that the pig shall first "make a frame," and he will fatten it afterwards. He succeeds without doubt in respect to the "frame"; it could hardly be otherwise on two scant uncooked meals a day. In respect to cooked food for pigs I am at one with your correspondent. The way our pigs throve upon it left no room for doubt. In addition we made it a practice to wash all root crops—Potatos, Parsnips, Beet, Artichokes, etc.—before cooking them, so that a clean, wholesome, and fattening food was the result. Barley meal scalded with the vegetables named forms an ideal food for pigs. To this end Jerusalem Artichokes might be grown on hitherto uncultivated ground. This crop requires but little attention beyond the planting, and the plant succeeds almost in any soil or situation. In summer our sties were washed down daily. Doubtless there are reasons to be urged against the keeping of pigs by cottagers and others in populous districts, though in view of existing circumstances it is time urban and other authorities relaxed their Eye laws, and, with a certain reservation as to cleanliness, made pig-keeping possible to the cottagers at home. It is doubtful if pigs can be kept on allotments, which are often far from the home, and cottagers handicapped for time in a variety of ways could never feed the animals properly. *E. H. Jenkins.*

HIPPEASTRUM RETICULATUM (see pp 126, 141).—The late Mr. B. S. Williams raised several choice hybrids of Hippeastrum reticulatum in the eighties, including those named Mrs. J. B. Pitcher, Mrs. Garfield, and Mrs. W. Lee. These varieties were all much finer in form and substance than the type, and the colours much deeper. All the flowers were distinctly reticulated, and the foliage had the line of white along the mid-rib. I am afraid they are now extinct in this country, but I believe they are still grown in the United States, as large numbers of the plants were sent to that country. *Hortus.*

JERUSALEM ARTICHOKE (see p. 140).—Your eminent correspondent, the Hon. Vicary Gibbs, declines to accept the general explanation of the word Jerusalem as a corruption of the Italian word "girasole." There is a possibility of defining existing words too literally, so that names may be mistaken for what they are intended to be: for example, Stilton, Cambridge, etc., are applied to certain foods not produced at those places; also plant names, such as English Iris, French and African Marigolds, Artichaut d'Espagne, and Artachaut de Jérusalem are both names of Custard Marrow (Patisson). So we have to accept their local and current meaning. M. Gibault, the gold medallist historian of vegetables, has in his work, *Histoire de Légumes*, a long article on the "Topinambour" from its introduction in the 17th century, and there states that the English name is a corruption of girasole. The popular French name, "Topinambour," is derived from a tribe of Brazilians called Tupinambas, who were amusing Paris at the time of its introduction. Your correspondent also states that "girasole" has never been used by Italians, but this is not correct, as a reference to a work on international names of plants, *Catalogo poliglotto delle piante*, compilato dalla Contessa di San Georgio, Firenze, 1870, gives girasol tuberoso as an Italian name, as well as Tartufo di Canna and Tartufo bianco. According to Heresbach, 1508, ex Johnston, the word Artichoke is a corruption of Alticocalum, compounded of the Arabic Al and cocalos, a Pine apple. Alcachofa is the Spanish name. The word Artichaulx is given with instructions for planting in a translation of Varro by Antoine Pierre, Poitiers, 1543. It may be a very difficult matter to give the Jerusalem Artichoke a new English name that would take on, as so many translations of meaningless descriptions have been given, such as Pear, Apple, Potato, Truffle, and may get relegated to old books, as has been the case with Love Apple. Miller, in 1748, described under Corona Solis this small flowering tuberous species as a native of Canada called Jerusalem Artichoke. It very rarely flowers north of Paris; the tubers are not used as food much in France, but they are much esteemed for cattle. Consequently the production of new varieties from seed is not resorted to, although there are a few distinct varieties, round, smooth, and irregularly long, purple and white skinned; also a pear-shaped variety, all of which seem to be reproduced constant in shape when well cultivated, but beyond the colour of the skin no particular notice is taken of them. Some time ago when the tubers of Helianthus decapetalus

were put on the market as a rival to the H. tuberosus, it received the name of "Helianthi," which seemed very appropriate. I would suggest that Helianto (es for plural) as a short name for Jerusalem Artichoke, as the word would retain the association of the generic and popular names. It is rather remarkable that so few of the Compositæ produce edible roots excepting Chicory, Salsafy, and Scorzonera. Sometimes Dahlias produce big clusters of tubers, but I have never heard of their use as food.—*J. Mac*.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

MARCH 26.—*Present*: Messrs. E. A. Bowles, M.A. (in the chair), W. C. Worsdell, J. W. Odell, W. Hales, and F. J. Chittenden (hon. secretary).

Plants from Salonika.—Mr. Bowles showed flowering specimens of a white form of Romulea Bulbocodium, with buff shade exteriors to the outer perianth pieces, and Ornithogalum divergens, both raised from bulbs sent from Salonika.

Seed from W. Indies.—Mr. Worsdell said he had compared a seed brought by Mr. Hales to the last meeting with specimens in the Kew Herbarium, and found it to belong to the genus Dioclea. The plants of this genus are widely spread through the tropics, and the seed floats long in the sea, being frequently washed up upon the shores of tropical seas.

Persistent fungus.—Mr. Worsdell also said that the fungus shown at the last meeting from Mr. Wilks was Russula nigricans. Every year this fungus growing in Mr. Wilks' wood at Shirley dried up and turned black in autumn, and persisted in this condition for a long time.

Polymorphous acorns.—Mr. Hales showed an acorn, one of many similar ones, in which three complete embryos had developed and given rise to three plants on germination. Others of the same batch of seeds from Sussex produced two and a few one plant.

Potato Scab.—Some specimens of the common Potato scab were shown. This disease, which is only skin deep, and does not appear to affect the weight of crop adversely, is due to the attack of a bacterium called Actinomyces chromogenus (formerly known as Oospora scabies). It is spread by infection from old tubers for the most part, and this may be obviated in a great measure by steeping the affected tubers before they are planted for sprouting in a solution of one part of formalin to two hundred of water.

MARCH 26.—The usual fortnightly meeting was held at the London Scottish Drill Hall, on the 26th ult. The exhibition was only small, but Orchids were shown fairly numerously, and the Orchid Committee recommended two awards to novelties and four medals to collections.

The Floral Committee awarded two Awards of Merit to novelties and nine medals to collections. Besides the handsome Rhododendron Ernest Gill and Primula Jewel, an interesting spike of Clivia (Imantophyllum) hybrida superba was shown by F. Berry, Esq., Hardwicke Grange, Shrewsbury. The flowers, borne on a large head, are of pale citron colour, which is deeper tone in the centre. This variety is said to have originated in Basutoland. Messrs. R. Gill and Sons, Falmouth, again set up a handsome collection of Rhododendrons, of which the richly-coloured Shilsonii, Cornubia, Thompsonii, and Thompsonii grandiflora were particularly noticeable. Mr. Reuthe, Keston, also exhibited Rhododendrons and various Alpines. Mr. L. R. Russell, Richmond, again showed Wistarias, Prunus triloba, and Pyrus japonica in variety. Messrs. J. Piper and Sons exhibit included the fragrant Viburnum Carlesii. Messrs. Geo. Bunyard and Co. showed Forsythia viridis, Corylus spicata, Magnolia stellata, and other flowering shrubs. Hardy flowers were shown by Mr. G. W. Miller, Wisbech, and Messrs. R. Tucker and Sons, Oxford. Messrs. Allwood Bros. contributed their usual fine exhibit of Perpetual-flowering Carnations, whilst Ferns, Cinerarias, Primula obconica, and Genista fragrans were shown by Messrs. H. B. May and Sons, Edmonton.

Floral Committee.

Present: Mr. H. B. May (in the chair), Messrs. W. G. Baker, W. B. Cranfield, John Green, W. J. Bean, John Head, Geo. Harrow, Wm. Howe, Charles Dixon, Chas. E. Pearson, H. J. Jones, John Dickson, W. P. Thomson, E. H. Jenkins, J. F. McLeod, C. R. Fielder, J. Jennings, E. A. Bowles, and R. C. Notcutt.

Awards of Merit.

Rhododendron Ernest Gill.—This magnificent variety is a cross between R. Lucombei and R. Fortunei. The truss is bold and compact, and the individual flowers are unusually large and of a bright rose-cerise colour. The variety may be described as a rose-cerise Pink Pearl. Shown by Messrs. R. Gill and Sons.

Primula Jubilee Jewel.—A cross between P. Juliæ and the garden variety "Hull's Blue" of P. vulgaris. The habit of the new variety is superior to that of P. Juliæ, whilst the flowers are considerably larger and of better form. The colour is lilac-magenta, and the flower has a gold centre. Shown by Mr. R. D. Webster, Newland, Newton Abbot.

Groups.

The following awards were made to collections:—*Silver Flora Medal* to Messrs. Allwood Bros.; *Silver Banksian Medals* to Messrs. R. Gill and Sons; Messrs. H. B. May and Sons, and Mr. G. W. Miller. *Bronze Flora Medals* to Messrs. Geo. Bunyard and Co., and Messrs. R. Tucker and Sons. *Bronze Banksian Medals* to Messrs. J. Piper and Sons; Mr. G. Reuthe, and Mr. L. R. Russell.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), W. Bolton, W. H. White, E. Brooman White, R. G. Thwaites, Purnell Bath, F. Sander, H. G. Alexander, E. H. Davidson, Frederick J. Hanbury, Walter Cobbett, J. Lucas, and E. A. Bowles.

Awards of Merit.

Dendrobium Alphonse Khanenia × *crassicaule* (*Bigamum*).—From Sir Jeremiah Colman, Bart., Gatton Park, Surrey, gr. Mr. Gilbert. A very pretty flower of fine size and great impressive effect. Dr. Rolfe not only preserving its attractive characteristics. The increase in size is interesting from the fact that D. crassinode, emdocharis × nobile) is much smaller than the other species used. The flowers of the variety are coloured rosy-lilac, the lip having a white base slightly tinged with yellow.

Brasso-Cattleya Doris Langley-variety "*Lord Rothschild*" × *B. C. Madame Ch. Maron*.—From Messrs. Flory and Black, Slough. This hybrid first flowered at the seedling stage in 1915. The large flowers on the mature plant now shown were of a bright rosy mauve colour with yellow disc to the lip, which has purple lines at the base and on the front lobe.

Groups.

Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, were awarded a Silver Flora Medal for a group of new and rare hybrids. Odontioda Arlet Odm. Crawshawiana × Odontioda Cooksoniæ) is a pretty novelty, with vinous red flowers, having slight white markings and rose-coloured lip, the yellow crest of which bears evidence of the O. Hallii in O. Crawshawiana. Choice new varieties included Odontoglossum eximium Orchidhurst variety (eximium × illustrissimum), with a fine spike of fifteen light violet-blotched flowers, and Odontioda Royal Gem, Orchidhurst variety (Odm. ardentissimum × Odt. Vuylstekeæ), with reddish-claret flowers quite different to varieties previously shown. Among species were noted the rare Odontoglossum nævium, and a small plant of the charming white Cattleya Schroderæ Hercules.

Messrs. Charlesworth and Co., Haywards Heath, were awarded a Silver Flora Medal for a group of well-grown Odontoglossums and Odontiodas, and cut spikes of Eulophiella Peetersiana and Neomoorea irrorata.

Messrs. Sanders, St. Albans, were awarded a Silver Banksian Medal for a group of hybrid Cattleyas and other Orchids. The new Laelio-Cattleya Dulce var. Sanderæ (C. Mendelii × L. anceps alba), with white flowers having a yellow disc to the lip, and a pretty light rose-coloured form of L.-C. Jay Sander were the most notable plants.

Messrs. Stuart Low and Co., Bayfordbury, Sussex, were awarded a Silver Banksian Medal for a varied group containing several showy Sophronitis crosses, including Sophro-Laelio-Cattleya Hon. Barbara Wilson (C. Fabia × S.-L. heatonensis), a variety of vivid rose colour with darker veining and mauve-purple lip, and S.-C. Ateens (C. Lawrenceana × S. grandiflora).

Sir Jeremiah Colman, Bart., showed Odontoglossum illustrissimum var. purpureum, the dark-spotted flowers having white margins and tips; also an interesting collection of cut Dendrobium flowers taken principally from plants raised at Gatton Park, and showing extraordinary variation in colour.

Dr. Michel Lacroze, Roehampton, showed the new Odontoglossum San Luis (eximium × Excmouthii), a variety of good size and rich colouring.

Pantia Ralli, Esq., Ashtead Park, Surrey (Orchid grower Mr. W. H. White), exhibited Brasso-Cattleya Digbyano-Schroderæ "Brad shawiæ" (B. Digbyana × C. Schroderæ alba). The large white flowers have a broad, finely fringed lip. The plant was specially interesting in being part of the original specimen for which an Award of Merit was given on April 5, 1904.

J. Ansaldo, Esq., Rosebank, Mumbles, sent Laelio-Cattleya J. Ansaldo (Haroldiana × aurea-cordata). It is a salmon-tinted flower, with ruby-purple front to the lip.

Messrs. Flory and Black showed their new Brasso-Cattleya Rosita (B. C. Hera × C. Dowiana), an attractive and distinct hybrid, with well-formed cream-white flowers of fine substance, with marginal flush and spotting of purple, the lip bearing dark claret-red markings.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Messrs. J. T. Bennett-Poe, Wm. Poupart, F. Herbert Chapman, Peter B. Barr, Francis Barnard, W. B. Cranfield, and Miss E. Willmott.

No award was made by this Committee.

A few novelties, including some promising Trumpet Daffodils, were placed before the Committee by Messrs. F. Herbert Chapman, Esq., Rev. M. C. B. Jardine, Wandsworth Common, showed a few vases of Daffodils, including the pretties Dutch Companion, Harlem, Hamlet, Lucifer, Scafell, and Sparkler.

Fruit and Vegetable Committee.

Present: Messrs. Jos. Cheal (in the chair), Wm. Poupart, H. S. Rivers, Edwin Beckett, A. Bullock, A. R. Allan, F. Jordan, W. H. Divers, E. A. Bunyard, John Harrison, George F. Bray, Owen Thomas, and Rev. W. Wilks.

Dr. H. Wayne (gr. Mr. E. Griffin), Buckhold, Pangbourne, exhibited 50 fishes of excellent Apples. All were typical fruits of good size and colour, and very firm flesh. The Society was asked to sell the fruit and hand the proceeds to the Red Cross Fund. The principal sorts were Cox's Orange Pippin, Blenheim Pippin, King of the Pippins, Anne Elizabeth, and Hanwell Souring. (Silver-gilt Banksian Medal.)

Messrs. J. Cheal and Sons, Crawley, showed splendid fruits of Crawley Beauty and Lane's Prince Albert, with smaller collections of Lord Derby, Beauty of Kent, Annie Elizabeth, and other Apples. (Silver Knightian Medal.)

Obituary.

J. Harrison Dick.—We regret to announce that we have received from New York the news of the death, from appendicitis, of Mr. J. Harrison Dick, Editor of *The Florists' Exchange*, of that city. It will be remembered that prior to his taking over his American appointment Mr. Dick was Editor of the *Journal of Horticulture* and earlier, assistant editor of the *Gardening World*. Before taking up a journalistic career Mr. Dick served for some time in his native country of Scotland as a gardener. He married a daughter of the late Mr. A. J. Bruce, of Chorlton-cum-hardy, who specialised in hardy insectivorous and other plants. Mr. Dick published several works on horticultural subjects, including *Commercial Carnation Culture*, *Sweet Peas for Profit*, and a yearly publication, the *Gardeners' and Florists' Annual*.

CROPS AND STOCK ON THE HOME FARM.

POTATOS.

IN districts favourable to early planting the main crop of Potatos should be planted forthwith. A thorough preparation of the soil is essential for Potatos, and an extra ploughing always repays when the soil is in a suitable condition for working, as it pulverises the clods and destroys weeds. The use of the cultivator afterwards aids further in providing a good tilth, which is all important. The question of manure is one for local circumstances. Farmyard manure is best ploughed in in the autumn, but in many localities it is put in the drills at the time of planting.

Banking the rows is favoured in many parts, while planting on the flat is practised in districts where the annual rainfall is low. Abundant space is an advantage both between the rows and between the tubers: a distance of from 2 feet 6 inches to 3 feet is advisable for tall, robust-growing sorts, and the tubers of such sorts should be set at least 15 inches apart in the rows. Dwarf varieties will succeed at a closer distance.

STORE CATTLE.

Heifers and steers are in demand to furnish the milk and meat supplies and they should be grown on vigorously into full size rather than an at tempt be made to fatten the steers prematurely. In the former condition they are much more serviceable than they can be as fat beasts. Two year-old heifers that were kept in the straw yard since November with the view of making manure and consuming rough hay or hay entirely on good Oat straw, Cabbage, and Mangold, should be given a change of food, such as grass in the open, still continuing the daily supply of Mangold. Eighteen Shorthorn heifers that have been treated here in the way advised promise to grow into useful milch cows by October, the bull having been turned out with them early in January. Heifers calving about October should be very valuable, as milk at that time is never too plentiful. With an abundant supply of rough grass which was saved for the ewes prior to lambing, and which they did not require, other food being plentiful, the heifers will quickly improve in appearance by the changing of their coats. Provide plenty of water and continue the Mangold ration of, say, four or six roots to each animal daily.

TREATMENT OF COWS BEFORE CALVING.

In some districts cows are more liable to suffer from milk fever than in others, owing mainly to the wet nature of the ground and the soft condition of the grass produced. Another cause of milk fever in cows is their being in too fleshy a condition at the period when they are approaching parturition. Milk fever may mean a serious loss, especially now that cows are such an enormous price—£50 is a common sum realised for a good animal of reputed milk production. Fortunately, milk fever is not nearly so common as formerly owing to the improved methods of treating the animals at critical periods, and also to prompt measures of treatment of the illness by the injection of a serum into the udder directly the cow is affected. Within six weeks of parturition the cow should be carefully dried off from previous milking. The animal will be benefited by that period of rest, although it is difficult to achieve this with some animals of a heavy milking capacity. In such bona cases the cows should be carefully fed on good Hay and straw, with water at all times available, in an open yard with shed accommodation so that the animals can get abundant exercise. When cows are thus treated, keeping them away from grass, milk fever is almost unknown, and the cows produce larger and more healthy calves than where they are kept more in the house and deprived of exercise.

I need hardly say the animals should not be allowed to get too low in condition, as the calves as well as the mothers will suffer. They should be given a small quantity of concentrated food—say, 2 lbs. of Linseed cake per day. *E. Molyneux, Swanmore Park Farm, Bishop's Waltham, Hampshire.*

MARKETS.

COVENT GARDEN, April :

Plants in Pots, &c.: Average Wholesale Prices.

	s. d.	s. d.

REMARKS. Cut flowers are coming in good demand throughout the week, and everything had practically cleared out on Tuesday and Wednesday, on Saturday nothing. The cold weather kept the supplies from being too heavy, and there were the usual illuminations in private during the week and Easter. Until 2 only small consignments arrived from the Channel Islands, which were soon cleared. The heaviest arrivals from the Channel Islands on Friday and Saturday, the consignments being well up to the usual size. The majority of these flowers will be useless and unsaleable when delivered.

Turnip-tops, per bag (72 lbs.) ...	2 0– 3 0	
Vegetable Marrows, per doz. ...	10 0–15 0	
Watercress per doz.	0 5– 0 10	

REMARKS. Supplies of Apples are now very limited. The new season's Black Hamburgh Grapes have made their appearance this week, and a few bunches of Gros Colman are still obtainable. There are fair supplies of Spanish Almeria Grapes. Forced Strawberries are on offer in limited quantities. A few English Pineapples (Queens) reached the market this week, and met with a ready sale. The following forced vegetables are on offer :—Asparagus (English and French), Cucumbers, Seakale, Mushrooms, Marrows, Beans, Tomatos, Peas, New Potatos, Broad Beans, Mint, Radishes, and English and French salads. *E. H. E., Covent Garden Market, April 5, 1916.*

GARDENING APPOINTMENTS.

MR J. S. COATES, late Foreman at Wynyard Park Gardens, Stockton-on-Tees, and formerly at Mointon Paddocks and Elvaston Castle, as Gardener to Captain GRANVILLE FARQUHAR, Esq., Dalton Holme, Beverley, East Yorkshire.

MR. W. FELSTEAD, Superintendent of Public Parks, Wolverhampton, as Superintendent of Parks and Allotments to the City of Norwich.

ANSWERS TO CORRESPONDENTS.

CORRECTION.—In the note on Cymbidium, Cymbidium, on line 6, column 3, should read Cymbidiums.

DECORATING NEWLY MADE GRAVE. *Hortus.*—There are various ways of fixing evergreens and flowers to the walls of a grave. Where the soil is of a clayey consistency they are easy to pin to the sides and ends of the grave. With friable soil it is impossible to fasten them securely by this means, and wire netting nailed to frames is necessary. A mesh up to 4 inches across may be used, according to the material available. A space of 4 inches at the sides and ends, both of soil and brickwork, is required for the smooth lowering of the coffin when the "decorations" are fixed in this manner. With regard to payment for such work, the rates would vary according to the locality.

NAMES OF PLANTS: *Barberis.* 1, Miltonia cuneata; 2, Deutzia gracilis; 3, Berberis Thunbergii.

RIGHTS OF TENANTS: *C. J. W.* An amateur grower, as distinct from a nurseryman, has no right to remove any trees, shrubs or plants from the soil, although they may have been planted by him as tenant; however this rule might possibly be held not to apply to such plants as it is customary to take up for "potting" purposes. The landlord would have the right to claim compensation for any growing things which were wilfully damaged, although not removed. Stones, forming a rockery, which merely rest on the ground by their own weight, may be removed.

WHITE FLIES ON BRASSICAS: *W. L.* The flies are known as Snow Flies, or Aleyrodes proletella. They are very common on Brassicas. Spray the plants frequently with soft soap and Quassia extract.

ON INCREASED FOOD PRODUCTION.

INDOOR TOMATOS

TOMATO seed should be sown in shallow pans or pots filled with fine compost. Cover the seeds with fine soil, and water the seed pans with a fine rose can. Place a sheet of glass over the seed pan and cover the glass with paper so the seeds germinate best in the dark or in a close atmosphere. As soon as the seedlings appear remove the coverings and place the pan on a shelf close to the roof glass to keep the plants stand. When the third leaf appears prick the seedlings into small pots singly and grow them in the same temperature as they were raised in. When the pots are filled with roots shift the plants into 5 inch pots, using a slightly rougher compost consisting of two parts fibrous loam to one part leaf mould, and one part manure from a spent Mushroom bed with a good dealing of soot. Grow the plants in a house having a temperature of 60°. Select the lightest position possible close to the roof glass.

There are two methods of growing Tomatos in pots and planted out on beds of soil. The latter method entails much less labour in watering. Whichever method is adopted the compost to be used will be much the same. Tomatos should never be grown in too rich soil, as this causes them to make gross growth which will not fruit freely. Use only good turfy loam from an old pasture chopped up roughly, one part leaf soil, one part old hot-bed manure, and a 6-inch potful of bone meal to a barrow load of soil makes a good compost. If possible, prepare it a little in advance of the potting time. If pots are used, those of 9-inch diameter are the most suitable. These must be carefully crock them, and place some turf grass side downwards, over the crocks to ensure efficient drainage. Pot the plants firmly, and leave about 3 inches of space to permit of a top dressing when the plants are beginning to set their fruit. Any kind of house suits the Tomatos, provided they are placed close to the glass, where they can get plenty of sun and air. The latter is most important as Tomatos will not thrive in a close, stuffy house. If possible wires should be stretched along about one foot from the roof and 10 inches apart, and the plants trained up these, allowing room for the foliage to develop. A little air should be admitted through the front ventilators, and the wires tapped every morning to distribute the pollen. After the first two trusses of fruit are set, and the pots are full of roots, the plants should be fed with diluted liquid manure, and given a little concentrated fertiliser at intervals. If too many fruits set in a truss the smaller or misshaped ones may be picked off. When the plants reach the top wire they should be stopped. If the foliage is very thick the ends of the branches may be taken off at the discretion of the grower to admit all the light possible to the fruit. The plants must not be over watered at this stage, but when necessary give a thorough soaking on two occasions, otherwise the fruits will crack. If the planting out system is preferred, place two 9-inch boards side by side on the stage and one edgeways each side of these, and fastened to the bottom boards. Allow a space of one inch between the bottom boards for the water to drain away. Over the top place some pieces of slate or pot-sherd, then a thin layer of small crocks, and some turf over all. Then fill nearly to the top of the boards with the soil, making all very firm. Turn the plants carefully out of the 5-inch pots and plant them with a trowel about 12 feet or 15 inches apart according to the variety. Certain varieties grow much stronger than others, and should of course be given a little more space. A light mulch of manure is helpful in conserving the soil moisture, but by no means, both for Tomatos grown in pots and in beds. The plants in pots to receive their more frequent feeding, fruits to be fastened to these placed out, for the reason that the soil in the latter is sooner exhausted. Feeding, however, should not be done to excess, or the plants would make rank foliage and little fruit. As soon as the fruits turn colour they should be gathered. *H. W. Thatcher, Garden, Port Lympne, Hythe, Kent.*

BRASSICAS

THE above produces a long succession of green vegetables over much of the year. They all require ample room to develop, and I recommend that in the early stages of growth and are all liable to the club root, or "finger and toe" disease. This destructive pest attacks most, if not all, Cruciferous crops, and is difficult to eradicate. The fungus is capable of infecting the soil, and where the disease has appeared the ground should not be cropped with Cruciferæ for several years.

Lime and lime does not occur in plants grown on "mineral" soils and much may be done locally in its ravages by dressing affected land with freshly slaked lime. The lime should be applied in the autumn, at the rate of 1 cwt. per rod. Seed of the autumn section of Broccoli may be sown outside at the present time. In the north we choose a warm position and a rather early date, as advantage results from getting the plants well established in pots passed through a sieve with a rough mesh. The same remarks may be followed with the winter and spring Broccoli sowing, the seed the first and third week in April respectively. Immediately the seedlings are ready for transplanting they should be done. It is important that they should not become drawn in the seed bed. Allow the young plants a space of 4 to 6 inches each way, and plant them in light soil. At the beginning of July those of the autumn section will be ready for transferring to their permanent quarters. Deep cultivation is advocated for Brassicas, having repeatedly seen its superiority demonstrated. The ground should be of good quality, but the comfort of fresh organic matter is to be avoided. It is better to plant in March or after than to use the watering pot, but if this is really necessary, water the ground thoroughly before and after planting. Broccoli should be planted in rows 2 feet apart, and 2 feet from plant to plant. The winter and spring kinds are ready for planting out in the manner described in the second and third week in June respectively. A trinity of good varieties for succession is **Veitch's Self-protecting**, Snow's Winter White, and Leamington. The cultivation of Brussels Sprouts in its main features is the same as suggested for Broccoli. It differs in that the seed should be sown under glass in March in a temperature of [illegible]. The seedlings should be pricked out [illegible] gradually hardened off, and transferred to their position in May. A distance of [illegible] necessary for the plant's development. Where it is desired, and the ground can be spared, a successional crop may be obtained by sowing under handlights as advised for Broccoli. The importance of a firm rooting medium for Brussels Sprouts would be difficult to exaggerate. The best variety I have grown of recent years is Bedfordshire. The plant forms "buttons" from the bottom to the top of the stem, and the Sprouts rarely burst. Savoys may be sown in a warm position in the light soil in April. The seedlings may be transplanted as suggested for Broccoli. They will be ready for the final transplanting in June and require a space of 15 inches each way. The variety Tom Thumb is of excellent quality. Cabbages may be had in spring, summer, and autumn. The experience of Mr Edwin Beckett with the variety Harbinger, see p. 104, seems to hold out hope that in certain conditions we may have Cabbage for winter use. Varieties of the summer section are sown under glass in February, those for autumn cropping in a warm position out of doors the first week in April, and those for spring use in the open garden in July. *Geo. H. Copley, Harewood Park, Bradford, Yorkshire.*

LEEKS

Your correspondent *G. H. H.* (p. 136) looks like Mr Thatcher's method (p. 104) entails more labour than is necessary for growing exhibition Leeks. I have never read a more complete and accurate method of growing good Leeks than that of Mr Thatcher. It is so simple, clear, and easily understood that a novice could not go wrong by following out his instructions. One ounce of seed sown under the conditions Mr Thatcher advocates would give better results than four ounces sown in the open ground. More than that, the work is being done really in mid-winter. The advantage of early planted Leeks is too well known to those who practise this method to be lightly set aside. One specimen grown under Mr Thatcher's method would be worth a dozen under *G. H. H.*'s directions, so where is the saving of labour? To grow Leeks, especially in holes 6 or 7 inches deep, is utter folly. In planting Leeks for market neither method is practised to this locality (Mid and East Lothian), where at least 400 acres are grown, mostly for the Glasgow market. Leeks are, in fact, one of the market growers staple crops, more care and attention being devoted to them than almost any other. Of late years one method has been to sow large areas thinly in drills about the end of March or beginning of April, and by giving them some top dressing occasionally have them ready for pulling by the middle of August. There is no blanching, but by inducing a quick, healthy growth the market is supplied with a good sample which can be disposed of at a very moderate price. This method has been the means of placing the vegetable on the market at a price our forefathers would never have dreamt of. Some growers who have less accommodation sow seeds thinly in boxes in February or in frames heated by manure, and after hardening the seedlings plant them out in the end of April in rows made 12 or 14 inches apart and 4 to 5 inches between the plants. The August sowings are made about the middle of March and the seedlings transplanted after Early Milan Turnips and McEwan Cabbage are cleared from the ground during June, July and the first week of August. To plant any later is only wasting time and material. The best results so far as size and quality are concerned are obtained from planting made in June and the first two weeks of July. As to the depth of planting, only as much as is necessary is put into the soil as allow the plant to be kept in its place by a gentle tap of the dibber. For a girl to plant 15,000 in a day there is not

much [illegible] to make holes 6 or 9 inches deep. Part of the tops of the leaves are cut off and as much of the root as to leave only about one quarter [illegible] in such so that the plants can be handled quickly. It requires more hands dressing and tending the Leeks to the planters than it does to plant them. These plants are put in only one at 5 inches or at most 4 inches apart in the rows, and 160,000 plants are required for an acre. With all the outcry as to the shortness of the supply of food, the Leek grower at present is very hard hit. The market price, or the price that the grower has to accept at present is [illegible] at most 1½d., for a bunch of twelve Leeks. Growers here were asked to grow vegetables for the Army and Navy, and having done so have been expecting that at last they would have easily got rid of them at a [illegible] price, but very few Leeks have been sold to either the Navy or Army, and I think market gardeners should know the reason why. Not a single Onion have been sold at a very [illegible] *Times* Mr. *Scarlett, Inverness, Mar* [illegible]

LEEKS SOWN OUT OF DOORS.

[illegible] to Mr. Thatcher on p. 104, no [illegible] to open air seed sowing, only [illegible] greenhouse and cold frame methods. The Leek is so hardy a plant that to supply [illegible] sowing [illegible] Leeks sown [illegible] Forget-me-nots to our minds be [illegible] used for raising under glass, but [illegible] Leek seed can be sown out of doors [illegible] results satisfactory for general use. [illegible] be sown in August and September in drills, like winter Onions, and left to stand where sown until the spring, future treatment then being as usual. My first digging of Leeks this season was from plants so grown. *C. Turner.*

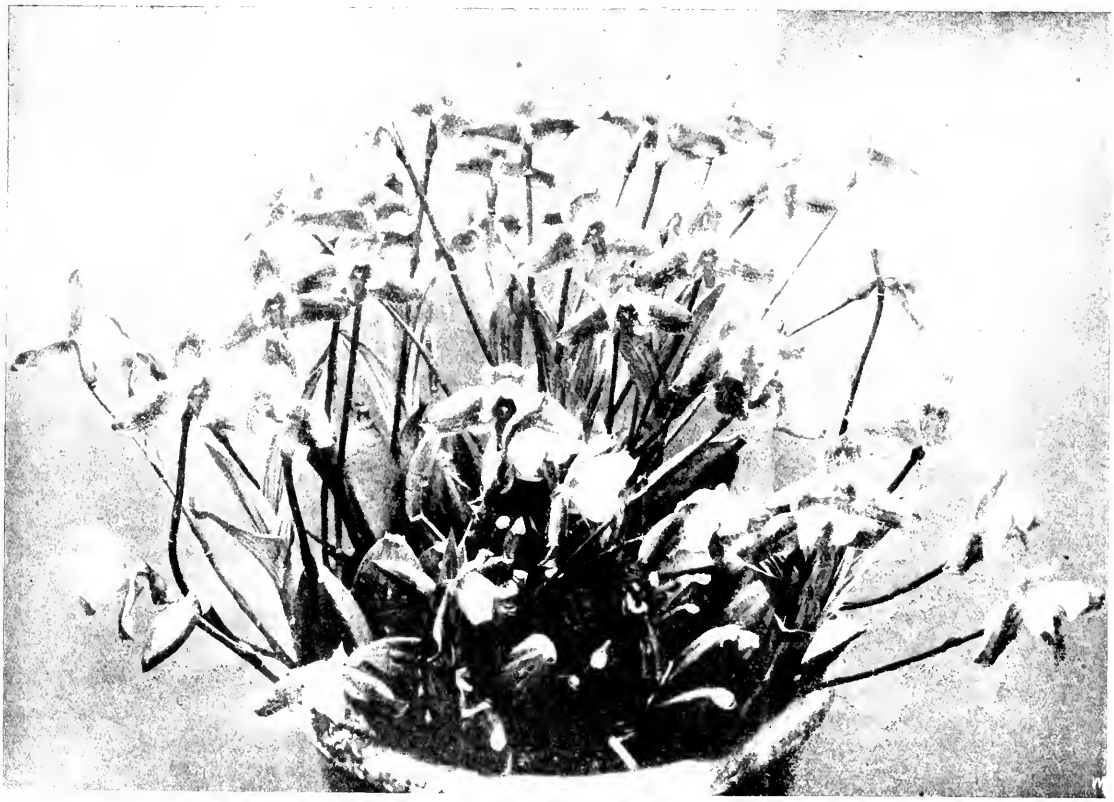
THE CARNEGIE DUNFERMLINE TRUST AND ALLOTMENT HOLDERS.

The trustees of the Carnegie Dunfermline Trust have arranged to distribute 15 tons of seed Potatos among their allotment holders and offer £90 in prizes for vegetable cultivation.

NOTICES OF BOOKS.

"The Peaches of New York."*

The arrival of the valuable fruit monographs from the Geneva Experiment Station is something of an event in these days when pressive of these is the vast body of legend and folklore which has the Peach for its subject in that country. The very interesting discoveries of Mr. Meyer, who is searching China for cultivated varieties of fruit and vegetables, also give some ground for upholding a Chinese origin. Travellers in Turkestan and Western Central Asia, such as Schuyler and Lansdell, speak of the marvellous growth of the Peach there, and its possible origin in this region and Eastward migration cannot be dismissed as unlikely. In any event the knowledge of this fruit goes back to very remote times, probably the earliest mention being that in the "Shi King," compiled by Confucius, and as Mr Hedrick does not mention this, it may be of interest to quote the following passage: "The Peach tree is



[Photograph by C. P. Raffill.

Fig. 69.—Lycaste deppei. Flowers greenish yellow blotched with brown. (See p. 156.)

[illegible] so little systematic pomological work is being done in this country. The high standard set by the previous volumes on Plums, Cherries, and Grapes is well maintained in the latest book on Peaches, and as the lines on which it is laid out follow its predecessors, and are doubtless well known to all students of fruit, they need not be recapitulated here. The history of the Peach, like so many of our fruits, still remains in its earliest periods a matter for investigation. At first considered a native of Persia, its original home is now pushed farther back to Central Asia, and even to China itself. Several facts lend support to a Chinese origin, and not the least important of these is the vast body of legend and folklore which has the Peach for its subject in that country. The very interesting discoveries of Mr. Meyer, who is searching China for cultivated varieties of fruit and vegetables, also give some ground for upholding a Chinese origin. Travellers in Turkestan and Western Central Asia, such as Schuyler and Lansdell, speak of the marvellous growth of the Peach there, and its possible origin in this region and Eastward migration cannot be dismissed as unlikely. In any event the knowledge of this fruit goes back to very remote times, probably the earliest mention being that in the "Shi King," compiled by Confucius, and as Mr Hedrick does not mention this, it may be of interest to quote the following passage: "The Peach tree is elegant and young, brilliant are its flowers, abundant will be its fruit. There are Peach trees in the garden; the fruit may be used as food." Mr. Hedrick, quoting De Candolle, names Theophrastus as the first to mention the Peach, but the Swiss author was mistaken in this matter, as he would have seen if he had read on and noted that the "Persian Apple" was placed among clothes to keep the moth away, an office for which the fragrous Peach is [illegible] formed. The fruit was, of course, the Citron. The origin of the Peach from the Almond, which was favoured by Thomas Andrew Knight, and later by Lindley and Darwin, is discussed and the author decides against this theory. It is interesting to note that the Almond has not been found wild in China according to Bretschneider, nor does a Chinese word exist for it.

* *The Peaches of New York.* By U. P. Hedrick, (state of New York Department of Agriculture, Albany. J. B. Lyon Company.)

the identification of Loniera being a mistake. We may, perhaps, picture a common parent like the philological "Aryans," whose nakedness science now clothes with inverted commas. These, however, are matters for the student, the gardener will be more anxious to know if the vast collection of varieties now gathered together in America, at Geneva and elsewhere, offer anything of interest or novelty. The answer is decidedly in the affirmative. Recent exploration in Chinese and Russian Turkestan has revealed that the variability of the Peach in European gardens does not disclose all its possibilities. From Tsinan, Shantung, comes a variety which will keep until February if wrapped in tissue paper, and it attains one pound in weight. A variety with white stones is also mentioned. The behaviour of these new types in America will be followed with great interest. The history of the introduction of the Peach into America is treated at length, and makes a very interesting chapter in the history of plant adaptation, but we must pass on to the main part of the book, namely, the descriptions of varieties, and refer the reader only to the very interesting chapters on culture, diseases, and to the instructive map of the distribution of Peach orchards in the State of New York. A slight feeling of disappointment will be felt by the British reader to find only two of the varieties figured in this country, one in the main text and one in the appendix and figured. We look to see a similar valuable work on the further amelioration of some of our old varieties such as Royal George, but alas! they do not prove acceptable in New York, and are thus relegated to the second list of varieties which receive more summary treatment. A study of the coloured plates, which are quite the best Mr. Hedrick has given us, show the varieties we know well, such as Waterloo, Alexander, and Hales Early, very much smaller than we are accustomed to see them, but reflection reminds us that on fan-trained trees are very restricted and probably more highly fed than the open standards which the climate of Geneva permits. There are doubtless many good varieties to come from America to our gardens, and when we realise how much we owe to that country for extending the Peach season, we only regret that we cannot pay back our debt in kind. In looking through the names of varieties described it is interesting to note in the "Early Red Mclocoton" a survival of the old Greek word which passed from Italy to Spain, and perhaps with the Jesuits to America. We also note that the "rule" which prevails in European Peaches that a serrate leaf is glandless does not hold in the American varieties, both glabrose and reniform glands being associated with this character.

The bibliography given is very full and useful, but we notice a curious omission that of "Die Amerikanische Fruhpfirsche" of Dr. Stoll, the only monograph published in Europe on American Peaches.

Many of the questions raised by a study of this work must be reserved till later, and it remains to felicitate Mr. Hedrick and his able assistants, Messrs. Howe, Taylor, and Tubergen, on a contribution to pomological literature which will, we imagine, for long retain its place as the standard work on American Peaches.

BULB GARDEN.

LILIUM BROWNII.

I BEGAN with much interest the note by Mr. Grove on "Lilies in 1917" in the issue of *Gardeners' Chronicle*, March 16. The introduction of this Lily is obscure, and notwithstanding all the recent writings of Messrs. Wilson and Henry we seem to be no nearer to discovering its original home. On the contrary, the frequent mention by collectors of "Lilium Brownii" has only tended to confusion, as the form usually referred to as Lilium japonicum colchesterense (or, as I think it should be properly designated, Lilium odorum).

Mr. Grove mentions that would-be growers, knowing no better, rely upon bulbs imported from Japan. He also states that L. Brownii is cultivated in nursery gardens in that country. For the last forty years I have seen and handled produce from most Japanese Lily importations, but never once have I come across a bulb of the true Lilium Brownii in any importation from Japan or China. Nor have I ever heard of its being grown in Japan.

I believe, however, that Lilium odorum has frequently been disposed of by dealers who ought to know better as Lilium Brownii, and this possibly accounts for Mr. Grove's statement. Twenty-five years ago it was plentiful and large quantities used to come from Holland and Belgium. The light peaty soil of Belgium produces bulbs of splendid quality, sometimes measuring from 10 inches to 12 inches in circumference. Of late years, stocks have so dwindled that this Lily has become almost unobtainable. I never struck me as being quick to [illegible] the stamens. If one of Mr. [illegible] flowers be dissected [illegible] stamens [illegible] most [illegible] L. odorum, which [illegible] 1903 and [illegible]

The [illegible] stated [illegible] parts of [illegible] I should [illegible] large [illegible] [illegible] [illegible]

FRUIT REGISTER.

APPLE KING OF TOMPKIN'S COUNTY.

THIS variety is one of the best late-keeping dessert Apples. The fruit is somewhat ribbed and large for dessert purposes, but it has high colour, good flavour, firm flesh, and keeps well till late in the spring. The tree is a strong grower, and the roots need pruning frequently, especially when planted in heavy ground. When this has been done and the plant brought into a fruitful condition it is a heavy cropper. Another point in favour of this American variety is that the tree is very free from canker. The fruits illustrated in fig. 70 were gathered in the first week in November, 1917. *A. B. Waddy.*

FIG. 70.—APPLE KING OF TOMPKIN'S COUNTY.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

SEAKALE.—Where root cuttings in sufficient quantities are at hand, now is a good time to plant them in land that is in good heart in rows made 15 inches apart, leaving a little less space than this between the plants in the rows. In the case of permanent beds the rows should be 3 feet apart and the plants 2 feet asunder. Plant three cuttings together in triangular fashion. Buds will probably be shooting from the thick end of the prepared cuttings, and when the roots are planted these crowns should be placed level with the soil. A top-dressing of salt applied either before or after planting Sea kale is beneficial, and especially on light soils. Remove all flower stems as they appear, and all but the strongest shoot. Seakale may also be propagated from seed sown now in drills made 2 inches deep and 15 inches apart, but propagation by cuttings is cheaper and better.

ASPARAGUS.—The best time to plant Asparagus is when the shoots are developing, and two-year-old plants are the best. Deep, rich, well-drained soil is necessary to grow good Asparagus, and the ground should be prepared in advance of planting as I advised on p. 112 in the issue for March 16. Mark out the beds as advised, and set three rows of plants on each 4-foot bed, allowing a space of 18 inches from plant to plant. Connover's Colossal and Sutton's Perfection are two excellent varieties, but such matters as position, kind of soil, and careful cultivation have most effect on the crop. Choose a dull day for planting, and carry out the work in an expeditious manner, exposing the roots to the air as little as possible. Now is a good time to sow fresh seed; thin the seedlings to one foot apart as soon as they are large enough to handle. Permanent beds should have all the roughest material raked into the alleys, and be dressed occasionally with a concentrated fertiliser. Salt is a good stimulant for Asparagus, especially on light soils, but should not be used until all danger from frost is over.

GENERAL REMARKS.—If fine weather continues endeavour to catch up arrears of work. Potatos, Carrots, Turnips, and other crops in frames need plenty of fresh air on all favourable occasions, or their growth will be weak. Thin the seedlings at an early stage of their development. Carrots should be 2 or 3 inches apart and Turnips 6 inches apart. Cauliflowers and Lettuce also require attention. Stir the soil amongst them when the conditions are favourable. Plants wintered in frames should be planted out in fine weather, and vacancies amongst other plants made good. The earliest sown Celery is ready for transplanting into boxes or frames provided with a moderate bottom heat. See that the plants are near to the glass. Peas and Beans that were sown in pots in pits or houses should be planted out after being gradually hardened. Put sticks to them at once, and some branches of evergreens by the sides to protect the tender shoots from cold winds for a few days. In fine weather stir the soil between all growing crops with the Canterbury hoe.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

PHAIUS.—Many species of Phaius, including P. Blumei, P. Sanderianus, P. Bernaysii, P. grandifolius, and P. tuberculosus, also such hybrids as P. Norman, P. Phoebe, and P. Cooksonii, which develop their flower-scapes from March onwards, should be top-dressed or re-potted as they pass out of flower. A suitable compost consists of three parts good turfy loam with the smaller particles removed, the remaining portion made up of A1 fibre cut rather short, and leaf-mould, with a liberal sprinkling of coarse silver sand. Ordinary flower-pots form the most suitable receptacles, and should be filled to one-fourth their depth with crocks for drainage. The plants have a robust root system and need ample pot room. Place the base of the plant a little below the rim of the pot to allow room for watering; make the soil firm about the roots and leave space on the surface for a layer of Sphagnum-moss. Water the roots sparingly at first, but when they are established let them have liberal supplies of moisture. Grow the plants in a house having an intermediate temperature, in a position where they will receive plenty of air without being subjected to draughts. Shade the foliage from strong sunlight. Fumigate the house on frequent occasions to destroy thrips, and sponge the leaves with an insecticide against scale insects.

MAXILLARIA.—Plants of M. candida, M. venusta, M. picta, M. stricta, M. nigrescens, and M. Mooreana are becoming active at the roots, and those needing fresh rooting materials should be given attention. The plants are best grown in pots or pans, filled with a compost consisting of Osmunda-fibre or A1 fibre, a little chopped Sphagnum-moss, and a liberal amount of crushed crocks. The receptacles should be well drained, and the materials pressed firmly between the roots. After they are re-potted grow the plants in a shady position and water them with extra care, pouring the water around the outer edges of the compost in order that it may not lodge in the young growths. Such species as M. Sanderiana and M. Lindenii that flower at this season are best grown in Teak-wood baskets, as the flowers often push downwards through the bottom of the receptacle. For this reason Fern rhizomes should be employed for drainage in preference to crocks. These two last-named species, also M. fucata, M. leucimata, and M. Hubschii, should not be potted until after they have passed out of flower. All the species named are best grown in an intermediate temperature.

ODONTOGLOSSUM.—Plants of Odontoglossum citrosmum having enjoyed a long season of rest are pushing up flower-spikes from the centres of the young growths, and may be afforded more moisture at their roots, but no water should be allowed to reach the centres of the growths, as this may cause the flower-spike to damp off and the young growth to decay. Plants of O. crispum or hybrids that are not flowering may be given more rooting space, but do not do this unless it is absolutely necessary. Plants with

young growths a few inches long that are growing over the edges of the pots may be turned out of their receptacles, all useless pseudo-bulbs removed, as much as possible of the old soil taken away, and the plants potted up afresh. After repotting afford water with great care, as an excess of moisture at this stage will cause the roots to perish and the pseudo-bulbs to shrivel. Plants that have recently flowered should be afforded but little water at the roots until after they are in full growth.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

PELARGONIUM.—Pelargoniums of the Show section will soon be showing their flower-buds, and as the pots are filled with roots stimulants should be given to the plants. Large specimens should be carefully staked. Keep the plants growing quite near the roof-glass in a light house, and admit plenty of air when the weather is warm and genial. Pelargoniums should not be shaded until they are in flower. Those which have been propagated for flowering in late autumn and winter should be stopped to induce shoots to break from the base. Let them grow slowly on a shelf in a cool house till danger from frost is past. They may then be plunged in a bed of coal-ashes in a sheltered position out of doors.

VIOLETS.—Violets propagated last autumn from cuttings should now be planted out in a position not exposed to the full glare of the sun. Choose ground that was dug deeply and liberally manured at the end of last year. The soil should now be lightly forked over and the surface levelled with a rake. A dressing of wood-seasoned soot previous to this operation will be beneficial. The large single varieties may be planted about one foot apart, and the double sorts allowed 9 inches. Examine the plants carefully for red spider before they are planted, and should there be the slightest evidence of this pest dip the whole of the foliage in a strong insecticide. The leaves should also be subsequently syringed with the insecticide at regular intervals during the growing season. Well water the plants to settle the soil about the roots. In the event of cuttings not being available old plants may be divided when they have finished flowering, planting the most suitable portions as advised for cuttings. Plants which have been wintered out-of-doors will be most suitable for this purpose, as the young shoots will not be so drawn and weak as those which have been grown in a frame. Spray the plants lightly every afternoon until they are established.

EUPATORIUM VERNALE.—This Eupatorium is a most useful plant for winter flowering in the cool greenhouse. If grown in cool quarters it will follow late Chrysanthemums, and the flowers at a time when white blooms are scarce. Plants which have flowered here this season have not been disturbed at the roots for two years, but they have flowered more freely, and the flowers have been finer than ever before. This season we shall slightly reduce the roots and repot them into receptacles of the same size as before. Eupatorium vernale is easily propagated from cuttings rooted in the spring. The cuttings may be dibbled into small pots in a sandy compost, and placed in a propagating frame.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

PENTSTEMON.—Pentstemon is rooted in frames may be transferred to the positions in which they are to flower. It is a curious fact that late planting with these flowers, or at least with the large-flowered section, has a very injurious effect on the production of bloom. Spring struck cuttings not sufficiently hardened may be kept in the frame for a little longer, but the planting of these too should not be long delayed. Plants of the hardy P. campanulatus should be pruned hard, and P. heterophyllus planted as soon as convenient. The latter plants need pinching, failing which the habit is loose.

BEET.—Ornamental Beet has long been given a place in the flower garden, and seeds may be sown at any time now, dropping three or so at every 9 inches apart. Besides the Dracæna-leaved, Whyte's Black and Dell's Crimson are suitable varieties for this purpose, and both are valuable from the culinary point of view. I am using Beet in conjunction with single Paw Dahlias. I should have noted in an earlier calendar that Carpots sown and intermixed with Godetia Double Rose are only slightly evident in summer. A stump-rooted variety should be chosen for this purpose.

SCARLET RUNNERS.—Runner Beans were admitted decorators of the flower garden in the 16th century, and in this year of the 20th century I am preparing to give them another innings in borders. To have early, strong plants it is essential to raise them under glass, planting one seed in a 5-inch pot, and germinating the seeds in a warm house, being careful to keep the plants well ventilated, and transferring them to a cold pit or frame at the earliest moment it is safe to do so. The plants should be pinched when quite small, and the pinching continued from time to time till the plant assumes a dwarf habit. Each plant when placed out of doors should have a space of at least 3 feet, and if more than one row is planted there should be a space of 4 feet at least between the rows. Gather the pods for use as they get large enough, and this must be kept in view when planting, so that facilities for getting to them may be provided.

FRUITS UNDER GLASS.

By W. J. GRIER, Gardener to Mrs. DUMPLETON, Keele Hall, Newcastle, Staffordshire.

EARLY PEACHES AND NECTARINES.—When the trees in the earliest houses are at the stoning stage, do not attempt to hasten the process by the use of much fire heat. When it is desired to ripen fruits very early more warmth must be employed after the stones have formed, and the temperature may be increased to 60° after the borders are closed, with plenty of moisture in the atmosphere. The night temperature however, should not exceed 65°, with a little air admitted through the top ventilators. The daily work of watering, syringing and ventilating should be carried out as usual. There need be no hurry about tying the shoots too closely until the fruits are at their second swelling, but when that stage is passed the final thinning and tying of the shoots should be done, and the crop completed. The thinning of the fruits should be done with great care; beyond removing any that are misplaced or very close to each other no more should be removed until after the period of stoning is passed, unless the crop be a heavy one, in which case it is advisable to lighten it somewhat, to prevent exhaustion of the trees' energy. A Peach or Nectarine fruit should have at least 9 square inches of surface, those growing behind branches or under the foliage never attain their proper size or flavour. Some effort should be made to turn or support these fruits with their points to the sun. Pieces of laths, or blinds tied on the trellis under the fruits will keep them in position. Directly the final thinning is completed established trees may be mulched and copious supplies of warm liquid manure, with occasional dressings of a concentrated fertiliser, must be given to the roots. A light mulching will be beneficial to young trees carrying large crops

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

STRAWBERRIES.—It is advisable to prepare for the making of Strawberry beds well in advance of planting, although it does not follow that the ground should remain fallow. Where it is intended to plant pot specimens that have been forced, the ground should be got in readiness for planting by the end of April, and planting may continue until mid-May. I have not found that planting earlier than this is on the whole satisfactory. Such forced plants will, if well cared for, yield a fair crop early in the autumn following. The varieties Vicomtesse Héricart de Thury and Royal Sovereign are suitable for the purpose. The former sort will give ripe berries about ten days earlier than the latter, and the two together will furnish fruits over a space of five weeks. Attention must be given to watering the plants until they are well established. Having lightly forked the old ball and removed the drainage, let them be placed quite firmly and well covered. Give a good watering at once, and apply a mulch at the same time, but light and shallow. Should the first blooms show somewhat prematurely, a few of these may be pinched off. Do not attempt to top with anything else; this would only lead to failure. These Strawberries should be planted in a sunny border; the two sorts recommended being with early varieties, the plantation can be useful in subsequent seasons. I have found the quality and firmness of Royal Sovereign to be improved in these late crops. Let the soil be dug deeply, and break it down at once preparatory to planting, use well-decomposed manure in the second spit, and before planting give a dressing of lime and hoe it lightly into the soil. Make the ground firm before planting. The soil for an ordinary Strawberry plantation in the kitchen garden should have been trenched for a previous crop, and when the runners are ready for setting out it will only require forking deeply. Nothing can be done to it just now, but having fixed on the site let the ground be kept clear of weeds and aerated by frequent hoeings. Whatever crop the ground may be carrying at present, do not let any of it remain after the first week in August, even if it entails a little sacrifice. Where late varieties are grown for special late cropping, a border facing north should be selected and held in readiness for planting the runners early in August. Like the rest of the garden, it may just now be under a crop, but do not neglect to keep an eye on its future use for Strawberries.

THE APIARY.

By CELSUS.

SPRING EXAMINATION OF HIVES.—From what I have learned from several very enthusiastic beginners a large number of colonies have been sacrificed by too inquisitive learners examining the bees during weather that was highly unsuitable. It is a pity they have had no one to guide them at a time when we can ill spare the bees; because first, the honey is badly needed, and second, the bees are urgently required to pollinate the fruit bloom. When the weather is warm in the middle of the day, and the sun shining brightly, an examination of the brood chamber may be safely made. The examination should be thorough. First it is essential to make certain that there is a queen at the head of each stock. Next it should be ascertained that she is laying, in which case the brood and eggs will be found in the central combs. This done, the queen may be stimulated to further egg production by uncapping some of the honey. Where the food stored is on the hot side give the bees a cake of candy; it is too early to give them syrup. In some instances bee-keepers space the combs widely; this should now be changed so that the space from centre to centre of the combs is 1¼ inch. Remove all empty combs and close up the brood nest by means of the division boards. Where colonies are found to be queenless move the queenless hive 2 yards daily towards another hive, and later unite the two stocks; or where a queen is known to be a drone breeder she should be removed and the colony united to another stock. In these days of sugar shortage it may be possible to remove a frame or two of sealed honey from a stock well provided for. Remove all dead bees from the floor-board, keep the entrances well contracted, wrap up the hive warmly, and see that the roofs are water-tight.

CLEANING HIVES.—Those who have a stock of old hives will be well advised to cleanse them thoroughly for the reception of possible swarms. All hives, frames, and floor-boards that have been in use should be thoroughly scalded. After this has been done they should be stood in a position exposed to the sun, and when quite dry painted with a carbolic mixture made of Calvert's No. 5 carbolic acid one part, and two parts of water. The empty combs should be sprayed with ½ teaspoonful of soluble phenyl in one quart of water, but before doing this fumigate the combs with burning sulphur

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER 41 Wellington Street, Covent Garden W.C

Editors and Publisher *Our correspondents would obviate delay in obtaining answers to their communications and save as much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Special Notice to Correspondents — *The Editors do not undertake to pay for any contributions, illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents*

Local News *Correspondents will greatly oblige by sending to the Editors early intelligence of local event, likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists*

Illustrations *The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of garden, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* EDITORS, 41 Wellington Street Covent Garden London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired the signature will not be printed, but kept as a guarantee of good faith*

APPOINTMENT FOR THE ENSUING WEEK.

THURSDAY, APRIL 18.
Manchester and N. of England Orchid Society meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 47°.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *This day*, April 13, 10 a.m.: Bar. 29·9; temp. 47° Weather: Rain

The Quality of Agricultural Seeds.*

The Seed Testing Station recently established by the Food Production Department has lost no time in getting to work. As early as February over 2,400 samples had been tested and reported upon. Of the seed Wheat tested, 47 per cent. of the samples germinated 95 per cent. or over; some samples, however, germinated only 12, 10, and even 6 per cent., and two were contaminated with the disease known as bunt. Seventy-four per cent. of the samples of Barley germinated 95 per cent. or over, but some poor samples germinating only 50 to 60 per cent. were received. Nine per cent. were badly infected with the spores of "closed smut."

The germinations of the samples of Oats were:—

40 per cent. germinated 95 per cent. or over.

54 per cent. germinated 80-95 per cent.

5 per cent. germinated 61-79 per cent.

1 per cent. germinated less than 50 per cent.

Of the Scotch Oats none germinated less than 80 per cent.

Most of the samples received had been well cleaned, but a few dirty samples contained weed seed, such as Black Bindweed, Cleavers, wild Radish, Cornflower, and Charlock.

As illustrating the seriousness of even a small percentage of impurity, the Report gives an example of a sample of Oats which, though showing less than ¼ per cent. of Charlock, was estimated to contain 10,000 seeds of this weed to the bushel of grain.

The samples of Peas and Beans were generally good, but in some cases only germinated from 36-56 per cent., and the seed had been attacked by the Bruchus weevil.

Of roots, the range of germination of Turnip seed was from 100 to 3 per cent., with an average of 86; Swede samples showed germinations ranging from 99 to 0 per cent., with an average of 82 per cent.; Kale, from 95 to 23 per cent.; Cabbage, from 95 to 56 per cent.; Beet, from 156 to 13 per cent., with an average of 88; Onion samples germinated in the best cases 100 per cent., and in the worst 4, with the very fair average of 76 per cent.; Parsnips showed similar diversity from 80 per cent. to 2 per cent.; and Carrot ranged from 71 to 6 per cent. It is evident from the figures relating to vegetable seeds that there are some very bad seeds on the market; for example, in the case of Beet, 62 per cent. of the samples germinated under 90 per cent., which, in view of the fact that each so-called seed—in reality a group of fruits—may throw two or three seedlings, is a very poor showing.

In the grasses and Clovers impurities and germination both show a great range of difference between the samples; the highest percentage of impurity was in white Clover, which showed an average impurity of 9·8 per cent. Red Clover ranged in germination from 97 to 2 per cent., and contained on the average 3·2 per cent. of impurities. The Report insists on the importance of the greatest care being taken in the purchase of the Rye grasses and red Clovers, which are sown in large amounts, and, as the figures given indicate, often contain considerable quantities of weed seeds.

In the case of red Clover, Dodder in greater or less amount occurred in 34 per cent. of the samples, and three samples contained over 1 per cent. of this parasitic weed. The Chilian Red Clover gave the highest germination, but was the worst offender with respect to Dodder.

The general conclusion reached by the Report is that there will be a large amount of low-grade seed offered to farmers this season, but that nevertheless good seed in moderate quantities is available in the case of the more important crops.

The Report reflects the greatest credit on the personnel of the Seed Testing Station, which must have worked at the highest possible pressure to achieve such considerable results in so short a time. We hope that a readable and attractive summary of this Report will be published and distributed widely. There is ample material in the Report for a series of extremely interesting articles, and we suggest that some bright-minded botanist with a touch of imagination should be employed to draw up from the material on which the Report is based illustrated articles, all of which should be directed to showing the wisdom of sowing good seed and the folly of sowing bad.

* *The Journal of the Board of Agric.*, XXIV., No. 11.

ROYAL HORTICULTURAL SOCIETY'S EXAMINATIONS.—The Council of the Royal Horticultural Society has decided that, in the General Examination, the questions shall cover a wider field in practical horticulture, and be less botanical. The standard for pass will be raised, and the examination itself divided into morning and afternoon sessions of 2½ hours each. The School Teachers' Examination will be divided into two sections, the Ordinary Pass and the Honours—the latter being optional. For the Ordinary, the questions will be made to refer distinctly to practical horticulture in school and allotment gardens, and candidates will have to produce a certificate of having done practical work, signed by some responsible person. The examination will be divided into morning and afternoon sessions of 2½ hours each. An Honours Examination will be added to the Ordinary for school teachers willing to take it. Candidates will also be allowed to specialise on such subjects as: (a) Hardy fruit growing; (b) vegetable growing; (c) hardy plant cultivation; (d) plant diseases and pests, any of which may be taken at the candidate's choice. A practical test of the candidate's knowledge and skill will also be made under the supervision of one or more of the examiners, centres for which will be established in various parts of the country. Before sitting for Honours candidates must have passed the Ordinary School Teachers' Examination. A separate certificate will be granted to each teacher passing with Honours.

GARDENERS' RATIONS.—We are informed that the British Gardeners' Association has received information from the Ministry of Food that gardeners are included in the list of those entitled to a supplementary ration, and will be guided under Class E. Enquiries should be addressed to the Local Food Office.

MRS. G. H BARD.—The many friends of Mr. GEORGE HENRY BARD, manager of Messrs JAMES CARTER AND Co.'s nursery at Forest Hill, will learn with regret of the death on Tuesday last of Mrs. BARD.

L.C.C. GARDENERS.—Following an application made to the London County Council by the British Gardeners' Association, an increased war bonus will be given to gardeners in the L.C.C. parks, the bonus to be brought to the level of that paid to other Council workers. The Council has increased the war bonus by 5s. per week, making 14s. in all. This increase is retrospective, dating from January 1, 1918.

HOME-MADE JAM.—There appears to be some doubt regarding the use to which sugar for home-made jam may be put. It is for fruit and Rhubarb, and, in the discretion of the local Food Control Committee, for Marrow. It is very probable that sugar for Marrow jam will not be granted in most districts. In making special allotments of sugar through the Local Food Committees under the scheme for providing fruit-growers with sugar for domestic preserving, no account will be taken of any sugar saved out of the weekly ration. The saving of sugar out of the domestic ration for jam-making not only does not constitute hoarding, but is a course desirable in the public interest.

SEED AND TRANSPORT.—According to what appears to be a well-informed statement,* the slowness of the transport of seed from America appears, in part at least, to have been due to a failure on the part of the responsible authority in America to recognise that seed is food. Hence, in spite of efforts made by growers, shippers, and officials of the U.S. Department of Agriculture, the railway transport of seed was held up, having to give precedence to the transport of food. We believe that every effort was made, and in good time, on this side, to facilitate the early arrival of seed supplies.

* *The Seed World*, Chicago, Ill., March 5, 1918.

EVE'S APPLE.

THE interesting article on St. Cecilia's Apple on p. 82 suggests to me that you might admit a few words on another Apple, equally interesting botanically, and, to some, far more interesting bibliically and mythologically.

No work, I believe, discusses the question concerning the species of the oldest recorded tree, yet the evidence that the Tree of Knowledge was a Pomegranate tree is remarkable. The Forbidden Fruit is the only fruit connected with man's religious history; the Pomegranate is the only fruit used symbolically in the Hebrew Church; and the explanation of these two facts seems logically to be that the Pomegranate was the Forbidden Fruit. And the Bible Concordance bears out this conclusion.

Botany, too, the Pomegranate answers remarkably to the requirements of the Forbidden Fruit. The Forbidden Fruit [illegible] as an Apple. The Pomegranate belongs to the same Order, Myrtaceæ, as the Pomegranate. Apple, Pear, Quince, Medlar, Thorn, Service, Rowan, Cotoneaster, Firethorn, Loquat, Amelanchier, Chokeberry, Photinia, Crataegomespilus, Sorbaronia, Pyronia, Sorbopyrus, Chaenomeles, Cydonia, Malus, Pyrus, Sorbus, Crataegus, Mespilus, Aronia, Osteomeles, Heteromeles, Eriobotrya, Docynia, Stranvaesia, Photinopsis, Pyracantha, Cotoneaster, Chamaemespilus, Amelanchier, Peraphyllum, Amelasorbus

on Kew. In his April contribution he asks why Kew has apparently so little influence on the character of ornamental gardens and pleasure grounds generally. I contend that Kew plays a much more potent part in determining the character of our shrubberies and other features of gardens than H. W. imagines. At the same time, I agree with him that the influence exerted is not in proportion to the wonderful advertisement the glories of Kew obtain through its millions of visitors. This, I think, can be fairly easily accounted for. Up to the time when a charge was made for admission, the bulk of the visitors were simply people seeking pleasure and a little interest, through observing the more sensational aspects of the plant-world as demonstrated in, for instance, a glaring collection of Begonias or Hippeastrums or in the truly beautiful breadths of Daffodils. Of later visitors, many, though keenly interested and observing, are quite unable to assimilate the enormous array of beautiful and interesting features presented by the gardens at almost any time of the year. There are probably very few who visit Kew with the main object of noting effects for application elsewhere. Hence Kew remains unique. There are, of course, other factors at work which circumscribe the influence of Kew. A sense of practicability mainly directs the average landscape gardener, whether operating in a public park or around a private mansion, to utilise plants which, though stereotyped, are easy of cultivation. He believes in a healthy Laurel rather than in a fastidious Rhododendron, to put it in the extreme sense. I agree, however, that there is a lack of enterprise on the part of both the amateur and professional. *Chas. W. Mayhew, Northumberland County Horticulturist*

LATHYRUS GRANDIFLORUS.—In the issue for Aug. 26, 1916 (p. 105), you published a note from me on the fertilisation and seeding of Lathyrus grandiflorus. Almost by return (allowing for the postal distance) I received a request from a gentleman at Adelaide, N.S.W., for seeds, if I had them to spare. I was unable to send them that year, but managed to save some seed during the past season, which I was pleased to send him, and which he has duly received. This little transaction has probably been the means of introducing a most beautiful plant to Australia. While on this subject, would it be possible to clear up what seems to be an error in Nicholson's *Dictionary of Gardening*, where L. grandiflorus is described as an annual climber? It is certainly a perennial climber. *G. Lamb, Mondelet, Hextable, Kent.*

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 9. The exhibition held in conjunction with the fortnightly meeting on Tuesday last was small, but included many items of interest.

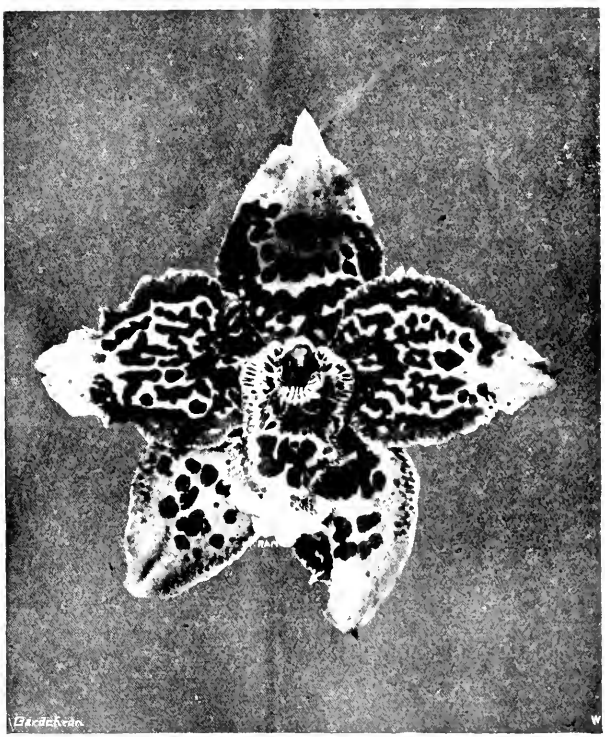


FIG. 72. ODONTOGLOSSUM JASPER VAR. ROCHAMPTON (See Awards of the Orchid Committee.)

As might be expected at an April show, Daffodils were conspicuous, the groups of these flowers consisting for the most part of either seedlings or the very choicest and latest varieties. The Narcissus and Tulip Committee recommended an Award of Merit to the variety Jeannette (see fig. 71).

As usual, Orchids were shown exceedingly well by trade growers and amateurs. Several novelties received awards from the Orchid Committee.

In the floral section there were one or two good exhibits of Roses, but the majority of the collections were early-flowering subjects, serving to remind us that as yet spring has but just begun. One new Rose received an Award of Merit, the name being Golden Ophelia; this was the only award given to a novelty in the floral section. Mr. J. ANSALDO, Mumbles, showed a pretty coloured Primrose of the shade known as "Bishop's Violet." (*Rep. de Couleurs*, II., 139, Ton. 4). The flower is named after Mrs. Ansaldo; no award was made to it. The Floral Committee awarded nine medals to groups, of which the best was a collection of hardy flowers shown by Mr. G. W. MILLER. This exhibit included seasonable subjects, such as Daffodils, a splendid variety of coloured Primroses, Fritillaria Imperialis, Aubrietias, Double Daisies, Primula Juliae, and Saxifraga Beauty of Letchworth. Messrs. B. R. CANT AND SONS showed excellent Roses, including a large epergne of their new variety, Golden Ophelia, as a centre-piece. Other conspicuous varieties were Joan, Laurent Carle, Mme. Ravary, and Dean Hole. Mr. GEO. PRINCE also showed Roses, with a background of yellow Rosa Banksia.

Messrs. R. GILL AND SONS showed Rhododendrons, the chief feature of their exhibit being a great mass of R. Falconeri, the trusses of which were of exceptional size and vigour. Several Chinese species were shown, including R. yunnanense (white, with red spots), R. Davidsonii (mauve), and R. Augustinii (blue). Of the large-flowered type, Lady Alice Fitzwilliam (large, white fragrant blooms), and Gill's Triumph (red), were the most noticeable. Messrs. H. B. MAY AND SONS showed their usual fine exhibit of Ferns, using as a centre-piece a healthy specimen of Platycerium grande. Groups of hardy flowering trees and shrubs were shown by Mr. L. R. RUSSELL and Mr. C. TURNER respectively: Mr. TURNER'S exhibit included many beautiful Magnolias, double-flowered Almonds, some with white and some with pink blooms, the very floriferous Prunus triloba, and a dark red Ribes sanguineum named splendens.

At the 3 o'clock meeting of the Fellows Mr. F. CHITTENDEN delivered an address on the subject of "Some Experiments in Potato Growing."

Floral Committee.

Present: Messrs. H. B. May (chairman), J. Green, H. Cowley, John Heal, C. R. Fielder, A. Turner, W. Howe, C. Dixon, John Dickson, W. P. Thomson, J. Hudson, W. J. Bean, J. W. Barr, W. Cuthbertson, S. Morris, J. T. Bennett-Poë, E. H. Jenkins, C. E. Pearson, R. W. Wallace, G. Harrow, and Geo. Paul.

AWARD OF MERIT.

Rose Golden Ophelia. A hybrid Tea variety raised from Ophelia, with medium-sized blooms of very pretty shape. The colour is pale, clear apricot in the centre, with lighter margins. The foliage is exceptionally vigorous, and very dark green. The variety is recommended for forcing, and the blooms would be admirably suited for coat-flowers.

GROUPS.

The following medals were awarded to collections:—*Silver Flora Medal* to Mr. G. W. MILLER, for spring flowers. *Silver Banksian Medals* to Messrs. R. GILL AND SONS, for Rhododendrons; H. B. MAY AND SONS, for Ferns; Messrs. B. R. CANT AND SONS, for Roses; Mr. G. PRINCE, for Roses; Mr. G. REUTHE, for hardy flowers and shrubs; Mr. L. R. RUSSELL, for flowering shrubs; Mr. C. TURNER, for flowering trees and shrubs; and Messrs. PIPERS, for shrubs and Alpines.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. sec. retiring), Frederick J. Hanbury, J. Wilson Potter, Pantia Ralli, E. R. Ashton, Fred Sander, Arthur Dye, J. Charlesworth, S. W. Flory, J. J. Lucas, W. H. Hatcher, W. J. Kaye, Walter Cobb, R. A. Rolfe, and R. Brooman White.

AWARDS OF MERIT.

Odontioglossum crispum Oakwood Triumph, from Mrs. NORMAN C. COOKSON, Oakwood, Wylam-on-Tyne (gr. Mr. H. J. Chapman). A grand hon raised variety, between O. crispum Pitcairnianum and O. c. Leonard Perfect, the latter famous variety influencing the fine shape and general characters of the flower, its rich ruby-red blotching being deepened and extended over the inner two-thirds of the segments in confluent blotches, the broad margins and tips being white. The lip is white in front with chestnut-red blotches in front of the yellow crest.

Odontoglossum Jasper var. Rochampton (see fig. 72) (*amabile* × *crispum*), from Dr. MIGUEL LACROZE, Bryndir, Rochampton (Orchid grower

Miss Robertson. A superb variety, and one of the best of its section, the flowers being large, of perfect shape, and beautifully blotched. The ground colour is white tinged with mauve; the inner parts of the segments are closely spotted with claret-red, and the lip bears dark red blotches in front of the yellow crest. The spike bore eleven flowers.

Odontioda Ernesto-Odier 'Wilhamina' × *Odontoglossum Ossulstonense*, from E. R. ASHTON, Esq., Camden Park, Tunbridge Wells. A pretty and distinct hybrid of the yellow ground section, of good size and shape. The segments are dark buff-yellow, and the greater part of the surface is heavily blotched with dark blood-red. The sepals have a rose shade and dark red blotches at the base; the much-crowded crest

PRELIMINARY COMMENDATIONS.

Odontioda Ernesto-Odier 'Charlesworthii', from Messrs. CHARLESWORTH AND CO., Haywards Heath. A large and finely formed bronze-coloured variety of the typical white petalled race.

Odontioda Amazone-Cooperi × *Odontoglossum Ossulstonense*, from Messrs. ARMSTRONG AND BROWN, Orchid Nurseries, Tunbridge Wells. A somewhat large bronze-coloured flower, with large and broad petals, the two parts of the segments being clusters of ruby-red blotches.

GROUPS.

Mrs. OSBORNE, The Shrubbery, Oxford, for Mr. Bennett-Poë, exhibited a selection of Orchids which had previously secured awards, including *Miltonia* 'Hyeana F. M. Ogilvie,' white, with a mauve mark on the lip; *Brassia Pittiana* 'Clinton Macmillan,' F.C.C.; Fowlerii varieties, and the rare *Cochlioda Noezliana* Harris's Sunrise variety. Mr. Bennett-Poë's malmaison carnations, for which a First Class Certificate was awarded on Sept. 26, 1911.

Messrs. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for a very fine display of fresh flowered Orchid blossoms and Orchid plants, including several kinds here noticed for the first time. Odontioda blossoms, Odontoglossum varieties, various hybrid Orchids, and the handsomely blotched flowers of *Cypripedium* species were also noticeable. Of Cypripedium hybrids, the Orchid Committee awarded Award of Merit to *C. Actæa* 'Betty' and Memoria Lord Kenyon,' both raised by Orchidhurst, and the Award of Merit to *C. Actæa* 'Mrs. Pethy,' the latter a pretty and distinct variety, with the petals and lip heavily spotted.

Messrs. CHARLESWORTH AND CO. were awarded a Silver Flora Medal for a group composed principally of fresh flowers and well-flowered Orchid plants and Odontiodas, with Lælio-Cattleya Britannia and Odontioda Margot Sander very well seen.

Messrs. C. E. WALTERS AND CO., Ryecombe, Sussex, received a selection of pictorially flowered Daffodil blooms, for which a Bronze Banksian Medal was awarded.

H. H. PEEL, Esq., Rosslyn, staged at Hill Top Mr. Thompson's choice Cyclodinum Lemoinum Rosslyn variety, raised between *C. Lemoinum* and *C. insigne* Sanderæ hybrid.

Narcissus and Tulip Committee.

Present: Messrs. E. A. Bowles in the chair, W. Poupart, W. B. Crundle, R. A. J. Bennett-Poë, Herbert Chapman, W. F. M. Copeland, Henry Backhouse, F. Burchard, Peter B. Barr, G. Bunhe, R. W. Wallace, the Rev. Joseph Jacob, and Chas. H. Curtis (hon. sec.).

AWARD OF MERIT.

Narcissus Jeanne (exhibited by The Misses Willmott), a comparatively large (2 in. of fine form and white flowers held well erect on stout stems that are nearly 18 inches long. The wide perianth segments are pale sulphur-yellow, and the well-behaved trumpet is light yellow, with a lemon tinge and has a frilled rim. The variety received the award as a show variety, but it promises to be useful alike for market and for garden decoration. Shown by Mr. W. F. M. COPELAND.

GROUPS.

Mr. COPELAND, Shirley, Southampton, showed nine nice varieties of Daffodils, and the Rev. G. H. ENGLEHEART staged a number of fine seedling Daffodils, including an outstanding, rich golden-yellow, APEX variety, larger than King Alfred, with a beautifully frilled trumpet, and waved perianth segments suggestive of descent from Golden Spur. This flower, some white trumpet Daffodils, and a seedling of the Red Beacon type, attracted much attention.

Messrs. HERBERT CHAPMAN, LTD., Crewe, staged a well-staged group of Narcissi. The display was rich in Poeticus varieties, including Actæa, Seagull, Sappho, Vilmorin, and Hermione, and near by, surrounded by many seedlings, were the King Alfred and other types, including Cassis, Queen of Bermudas, White Queen, and Great Warley varieties. (Silver-gilt Banksian Medal.)

Messrs. BARR AND SONS exhibited a large number of varieties and named varieties. Many of the novelties were represented by one flower only. Of mixed sorts we made special note of the flame-coloured Red Beacon and Red Emperor, the latter of no mean rank as to the popular Emperor. Cleopatra, Sunrise, and Flower of Spring. (Silver Flora Medal.)

Mr. C. H. CURTIS, Alverstoke, Hampshire, staged about 100 fine cut blooms of Narcissi, chiefly the varieties recently in Barr's Record. (Silver Banksian Medal.)

Mr. W. F. M. COPELAND exhibited seedling Narcissi. Each flower of the group received an Award of Merit, the varieties Queen Elizabeth, Madge, and Mucha were of considerable beauty and interest.

Mr. JARDINE showed a few Daffodils grown in his garden at Balham.

Fruit and Vegetable Committee.

Present: Messrs. J. Cheal in the chair, W. Poupart, Owen Thomas, Edwin Beckett, W. H. Divers, G. P. Baker, and W. Wells.

AWARD OF MERIT.

Lapageria Rosea Superba. Four examples of specimen size and in fruit were both attractive and interesting. We understand that the plants were raised from Bramleys Seedling, a variety of note in the general estimation of all admirers of that popular table fruit. Shown by Mr. HERBERT NORTHEY, Sandy.

The Committee made a visit to the Potato Conference meeting to meet those in charge of the Wisley Gardens, and for history of the day see report on April. Harry Pring, for which a Banksian Medal was awarded. Shown by Mr. W. PRINCE, Crown Gardens, Bedford Road.

BRITISH FLORISTS' FEDERATION.

APRIL 3. Only about twenty retail florists were present at the meeting of the Association held at Essex Hall, Strand, on the 4th inst. Mr. George Munro, junr., gave a statement of work accomplished. Mr. W. H. Page referred to the advantages of co-operation among growers and salesmen during the past year; whilst Mr. Robert H. Page emphasised the point that all retailers should join an organisation already established. Mr. Morgan Veitch said that legislation during war and difficulties after the war might be such that the flower trade would find itself left behind unless every section of it combined for the common good.

Mr. C. H. Curtis referred to some special lines in which the Federation had rendered great assistance; he suggested every member should act as a local hon. sec., and expressed the hope that ere long there would be a Horticultural Advisory Committee to assist the Board of Agriculture.

A resolution was passed asking the Royal Horticultural Society to call a meeting of representatives of trade associations for the purpose of taking steps to secure the formation of a Board of Horticulture.

Some of the retailers present felt that the Federation should offer them some inducement to join. Mr. Ladds and the president pointed out that the retail florists were not organised where as the growers and salesmen were, and were now offering retailers all the help that a successful organisation could afford, and the retailers would have their own sub-committee to deal with retail matters.

CROPS AND STOCK ON THE HOME FARM.

REARING CALVES.

THE various orders issued by the authorities may so considerably that methods of procedure require frequent readjustment. Milk and butter are so valuable that every means should be taken by the dairy farmer to rear all the better calves possible in order that the milk supply shall not be lessened in the future. The recent order to kill bull calves necessitates the home consumption of more milk, although these animals should be killed as early as possible, to save milk. In the case of pedigree Shorthorn calves of either sex, where size and quality are of almost importance to future stock purposes, the calves should be allowed to run with their mothers several months, which is the means of providing ample home and flesh. To the stock farmer the economical rearing of heifer calves is much more important in the saving of meal required during the winter. He calf should be allowed to feed from its mother for three days after birth. After that period it should be removed to a separate box and fed artificially. In the morning and evening give to each two quarts of new milk, preferably that from its parent. At the end of a fortnight alter the treatment by adding one quart of separated milk to the four quarts of new milk for another two weeks. Then, in place of the new milk, substitute warm skim or separated milk, adding some calf meal. I prefer Bibby's Cream Equivalent, of which one short pint is mixed with the milk. Continue this treatment for six weeks, then at that stage, or earlier, give the animal a small quantity of good meadow hay.

When the calf is three months old, gradually discontinue the meal, but give the separated milk, to which add a little water, for so long as is convenient. At that stage the calves should be given a little hay, chaff and concentrated food. The best food for calves is undoubtedly oil-linseed cake containing 9 per cent. or even 10 per cent. of oil, and crushed Oats, but both of these foods are almost unobtainable now. In lieu of this fact recourse must be had to some other form of cake, of which there are several on the market. If the calves are having separated milk with their calf meal, one part of cake is sufficient. At four months old in the place of cake and Oats, give them an ample supply of good hay, and at a later stage feed them daily with cut Mangold, just a handful to start with, increasing the quantity as it is seen that no harmful effects as scour result. To the Mangold add a sprinkling of cod liver oil or linseed, or any other approved appetiser.

The time for turning calves out to grass varies according to the time of birth. Many farmers and cowkeepers put them out much too soon, causing them to become "pot bellied" "too extended in stomach. An empty barn or an open shed where it is dry and warm, is much the best place for calves, and certainly until they are eight, or even twelve, months old. As a guide for an early born out, a September calf might at most, be given a grass run in May or June. In any case, it is better to err on the side of retention in the shed especially if the calves can be given green Vetches or Trifolium incarnatum in June and July, to be followed after with Cabbage.

FEEDING DAIRY COWS.

For improving the quality of the cream, and consequently the butter, I am a firm believer in the use of some form of concentrated food. I prefer Bibby's Dairy Cakelettes, which are in nut form, more easily handled, and keep better in bulk, than the cakes at one time made. By the addition of this cake the high colour of the butter is maintained right through the winter, at a time when there is little or no grass, the food being chiefly Mangolds, Cabbage, and Hay. No doubt the Tankard type of Mangold, with its highly coloured flesh, gives colour to the butter as well as possessing much nutriment. Now that the grass is growing freely it will be wise to conserve any concentrated food in hand for next autumn and depend on the natural food for the present. Have a daily ration of 45 lbs. of cut Mangold will be continued until the cows lie out at night, which usually commence in the second week in

May. In addition to the Mangold, an allowance of 5 lbs. of long Hay is given, which is considered to be better than chaffed Hay, as when the latter is used the cows are apt to eat it up too quickly, which from a digestive point of view is not an advantage. In all cases roots should be given *after* milking, to prevent any risk of taint in the milk, the Hay or cake being given before milking. Some give Oat straw in the place of Hay, but I doubt if that compares with good quality meadow Hay, which for cows is superior to field Hay, Sainfoin Clover or Rye grass.—*E. Molyneux.*

Many of the Flowers and Plants which are normally sent from the Channel Islands are now being sent from the Scilly Isles, and Penzance, which are not so much affected by the present restrictions as those which are nearer to the Continent. The shipments of French flowers are also coming in more regularly. The majority are unsold by the early afternoon, and are being sent on the journey. It is supposed that the supply of these flowers may be stopped altogether before the remainder of the season, owing to transport difficulties. Large consignments from the Channel Islands are now arriving this week in an unsaleable condition, caused by the delay in transit. Hundreds of boxes have to be thrown away, and many more sold at a very low price. There is an abundant supply of Roses. Sweet Peas, both white and coloured, are being offered. There is only a limited supply of Lily of the Valley, of medium quality.

REMARKS.—The Apples now available, long suppose are mostly American and English grapes are in bunches of from 6 lbs. to 10 lbs. each. There are now in the Market Belgian Endive, Cucumbers, Mushrooms, and Watercress. Belgian Endive is a new vegetable to the Market, and is of good quality. Asparagus (English and Continental), Cauliflowers, Mustard and Cress, Radishes, Spring Onions, and Turnip tops are all in good supply. Cauliflowers and Tomatoes are [illegible] *Market, April 19.*

Obituary.

G. H. GREEN.—We regret to announce the death of Mr. G. H. Green, of Fir Tree Hall Gardens, Stubbington, at the age of 60. Deceased went to Enville from the Royal Botanic Gardens, Regent's Park, as lad, as foreman of the conservatory, subsequently to the Forest in England, under the late Mr. Edward Bennett, and ultimately succeeded him as head gardener, a position he occupied for a period of 25 years. On the death of the Countess of Stamford some 15 years ago Mr. Green retired from active service, but was permitted to continue to reside in the gardener's house. The glass houses at Enville contained fine collections of Orchids, stove and greenhouse plants whilst many houses were devoted to the cultivation of fruits. Mr. Green leaves a widow and a large family of high class gardeners. He was survived by two sons, and two daughters. The eldest son is in Canada; another son was for many years manager of Messrs. W. Bull and Sons' seed establishment.

ANDREW ROBESON SARGENT.—We regret to learn from the *Gardeners' Chronicle of America* of the death of Andrew Robeson Sargent, son of Professor Charles S. Sargent, of the Arnold Arboretum. The late Mr. Sargent was a landscape architect, and took to it associated with his father in many of his activities as a naturalist. He was also associated with his brother-in-law, Major Guy Lowell, an architect who attained distinction by his plans for the Boston Art Museum and other important buildings in various parts of the United States. In 1909 the late Mr. Sargent made a journey through Russia, Korea, Java, and other European and Asiatic countries for the purpose of collecting plants.

THE WEATHER.

THE WEATHER IN SCOTLAND

The weather during March was mild, unusually dull and dry. With 16 days of precipitation and 10 rain days there was a total fall of 1.08 inch, the driest day being the 30th, with 0.38 inch. There were 10 sunless days in the month, the 22nd was a sunless day, yielding 9.2 hours of sunshine, the total for the month was 76.5 hours, an average of 2.5 hours per day, and a percentage of 21. The barometric pressure was a mean of 30.1 inches, varied between a highest of 30.47 inches on the 6th and a lowest of 29.15 inches on the 31st. For the month the mean temperature was 41°, the mean maximum being 47.5° and the mean minimum 34.5°, giving a mean range of 13°. On the 24th we had the highest maximum of 60° and on the 1st the lowest minimum of 28°; the lowest maximum of 3[illegible] on the 3rd and 8th, and the highest minimum of 43° on the 21st. On 6 days the temperature fell below 32°. On the grass the mean minimum was 30°, with a lowest of 22° on the 3rd and 13th; there were 16 nights of ground frost. At 1 foot deep the soil temperature fluctuated between 39° and 45°, standing at 42° at the end of the month. The prevailing winds were easterly and westerly. *James Mallock, Scr Andrews Provincial Training College Gardens, Kirkton of Mains, near Dundee.*

GARDENING APPOINTMENT

MR. C. J. **Cradwick**, for the past six years Gardener to Col. F. C. GRANT, Shrubcrne Hall, Shrubcrne, Dorsetshire, as Gardener to Col. Bertram Bob Pitt, Belvedere, Kent.

ANSWERS TO CORRESPONDENTS.

BEES FOR EXAMINATION: *Ipt.* There is no evidence of disease, either in the comb or bees sent. It would appear from your letter that the colony was a weak one. In the comb you submit for examination the brood is perfectly normal, but the presence of much mould seems to point to a leaky roof, and, as you suggest in your query, the stock has not probably been wrapped up warmly enough to maintain the requisite heat of the cluster. The variety is the ordinary English bee.

NAMES OF PLANTS: *East Berks.* Norway Maple (Acer platanoides).—*Delta.* Ranunculus Ficaria (Lesser Celandine).

NURSERY: *L. B.* Keep the bulbs dry until the beginning of July. They should be firmly rooted in the pots, but as you say your bulbs move easily from the top of the soil repot them in July and start them into growth. The Nerine flowers in the autumn, the leaves and flower coming up the same time.

SEAT BED: *E. L.* No doubt Sutton Bed will be more largely grown this season owing to the cost now that its merits as pig food are more widely known. Boiled and mixed with meal the roots form an excellent food for pigs after fattening. They may also be given uncooked to pigs in reasonable quantities and fattening quickly. As food for poultry Sutton Bed is useful when cooked and mixed with meal. The cultivation of the plant is quite simple; it may be grown like garden Beet, except that more space is required, as the foliage is rigorous. The white variety is the more commonly grown.

VINERY WITH EIGHT VINES: *H. T.* You will probably find that although the outside border is well lined, the roots have gone through the wall and extended to the soil beyond. This being so, and the walled in part being not less than 3 feet wide, it would be of little use the end of August to cut a trench and sever any roots which may have extended beyond the confines. Meanwhile, apply superphosphate, and sulphate of ammonia, 1 lb. to the square yard, with a good sprinkling of wood ash or lime, and fork these to the surface. Fork the materials not more than one or two inches below the surface. The application of liquid manure may be repeated at the end of June. If the summer and the position of the border do not supply a light mulching of stable manure, June. A dressing of slaked lime, one foot to the perch, applied in late autumn, would probably be beneficial, but must not be applied at the same time as the previous manure. Blood makes a good manure, but it is offensive in use, and it takes a considerable time to come into action. The best way to employ it is to mix it with soil before it will decompose and be useful to applying to the Vine border in winter or early spring.

THE ROSARY.

USEFUL ROSES.

I AM so entirely in agreement with the main proposition in the letter of *R. P. S.* (p. 92) as to the difficulty of naming the best Roses for any garden out of one's own district, and have so often stated it myself that, except as a matter of courtesy, it might seem that his letter scarcely calls for a reply, but he raises some interesting questions, as also does *Rosa Rubra*, who writes on the same subject (p. 123).

Varieties of Roses vary greatly in different districts, and even in different gardens. In a garden in the North of Scotland I have seen Richmond making stronger growth than Hugh Dickson, though with me the latter will make shoots 7 feet long, while Richmond, which does well with me, seldom exceeds 4 feet. Moreover, Roses will behave differently in parts of the same garden. I remember Mr Leslie telling me that the beautiful exhibition flowers that have so often brought him victory at exhibitions were invariably cut from a particular part of his garden.

In forming an opinion of the most useful Roses one tries, of course, not to consider one's own garden only, but to bear in mind also the Roses of one's friends. The late Mr. Mawley's adherence to the proposition stated by *R. P. S.* was well known, yet no one, I think, was more assiduous in collecting and collating the views of others on popular varieties.

It was at his instance that year after year, in the *Rose Annual*, we reviewed the opinions of well-known Rose growers on varieties suited for various purposes from a mass of material that he had most carefully collected in elaborate detail from all parts of the country. But, after all, one can only know a Rose by living with it, and that can only be done in one's own garden. In the gardens of our friends we see the Rose at intervals, and more or less cursorily, so that our notice is chiefly attracted by plants which happen to be at their best or worst.

Rosa Rubra and *R. P. S.* are both kind enough to tell us of the varieties which succeed best with them. Both of them include Antoine Rivoire, and seven or eight years ago I should have agreed with them. I still grow a large batch of that variety, which is very charming early in the season, but the summer flowers, by which I mean those of the second crop, produced in August and onwards, are now so poor with me that I conceive it is surpassed by others, possibly Ophelia, and no longer holds a place in the first rank.

On Caroline Testout I think we all agree; for hardiness and general good behaviour it has had few equals, and Hugh Dickson, approved by both your correspondents, is undoubtedly a fine Rose, particularly when pegged down. It is, as Mr Mawley once said, a Rose one can feed proud of. Its failing as a garden Rose is the long shoots of its autumnal growth, which quite spoil any decorative effect in the garden at that period. Lady Hillingdon is placed high by *R. P. S.*, and it is a lovely Rose, with very attractive foliage. I sometimes think that though a Tea variety it prefers a rather more holding soil than my garden can afford it, for though I grow between 40 and 50 plants of this Rose in two borders, and have many pleasing flowers in the course of the season, I fail to get many of the long-standing flowers well set up on stout stems, which are so well shown by Mr Frank Cant and Mr Marriott. Possibly more attention to disbudding might remedy this, but Mr Frank Cant has himself pointed out that a Rose which requires disbudding is somewhat defective as a decorative Rose for the garden.

Rosa Rubra's list is a good one, but it includes three varieties I cannot accept in the first class for garden purposes. Duchess of Wellington is lovely in fine weather; I grow a good bed of it, and would not be without it, but it is most annoying when one is watching it just coming into flower to experience a wet night and find next morning all the outer petals glued together and the flowers worthless. In this country it is a serious defect. Mrs Foley Hobbs is a lovely flower when set up in a box, but it has three serious faults for a garden: (1) It hangs its head; (2) it is too apt to catch cold, especially early in the season, and form flowers with hard, green centres; (3) too many of the flowers as they grow naturally on the plant are, as it were, hidden by the outer petals, and it is only when gathered and placed in a vase or exhibition box with the outer petals pushed back that its beauty of form can be observed.

Juliet is the worst Rose in my garden for black spot, and scarcely flowers after the first bloom is over. Its peculiar colouring is not pleasing to me, but this may be my bad taste.

Finally, I should like to say a word about Papa Gontier. This is almost my ideal of a decorative Rose in many respects, but I gather neither of your correspondents are quite satisfied with it in the open. When I pruned it like other H.T.s I had much the same experience as *R. P. S.*—the plants gradually got weaker, and became useless. Since, however, it has been removed from the beds and planted in a dry border where pruning has practically been confined to the removal of old flower stalks, it has made good growth and persisted year after year. Even better results are obtained from the climbing form on a south wall where pruning is restricted as far as possible. After ten years or so the original plant shows some signs of wearing out, but younger plants will take its place when this occurs.

THE "ROSE ANNUAL."

The National Rose Society has recently issued to its members its *Rose Annual* for 1918. In general character and appearance the volume follows the example of its predecessors except that, doubtless owing to the war, coloured illustrations are absent; it is, however, plentifully illustrated with reproductions of photographs in black and white.

The readable part of the volume (which is prefaced by some reports and accounts which seem rather out of place) begins with a pleasing account, written by the Editor, Mr. Courtney Page, of the Rev. F. Page Roberts, a popular ex-president of the Society, who, after 40 years of Rose growing and showing, is still doing much good work for the Rose. This is followed by a number of articles of considerable interest to rosarians by various writers. It is pleasant to see Mr. George Laing Paul again among the authors; he contributes an article on Rose growing by the sea. The cold winter of 1916-17 has naturally called for notice, and Rose growers will find the present volume quite as interesting as its predecessors. *White Rose*

SPRING FLOWERS.

A YEAR ago I tried in vain to discover from books the botanical difference between Anemone montana and Anemone Pulsatilla. Some authors gave differences in the foliage, but a short examination of herbarium specimens was enough to show that these differences do not exist in nature. Although my plants have grown undisturbed for several years in their present positions and within a few feet of one another, the differences between the two species are, if my memory is correct, much more obvious this year than they have been in former seasons. I should mention that I collected the plants of Anemone montana myself on the upper part of Monte Maggiore above Abbazia in Istria, while my plants of Anemone Pulsatilla are seedlings of the ordinary garden type. Each plant of montana bears from 10 to 30 flower stems, rising to a height of 15 inches, with a tuft of reduced leaves half way up the stem. The stems of Pulsatilla are much shorter and the tuft of leaves is situated almost immediately below the flowers. Moreover, the flowers of montana always droop or, at most, face horizontally, while those of Pulsatilla, when fully developed, are held erect and open very widely. The colour of montana is a very dark purple, and I found no variation in the wild state; that of Pulsatilla is always of a paler mauve-purple, except in the rare chocolate-coloured form, which, by the way, when crossed with pollen of the usual form, gives plants with richly coloured, dark red purple

flowers. In the wild state montana never seemed to produce more than one or two flower-stems, and yet here these same plants produce as many as thirty stems.

How many gardeners grow the real Iris pumila? Not many, it appears, for the plants so labelled are usually forms of I. Chamaeiris. Even the so-called pumila coerulea is probably a hybrid form. In good loam, Iris pumila is capable of forming the most amazing sheets of colour, but in my sandy ground the surface soil has to be constantly enriched and refreshed, or the plants dwindle. The chief interest lies in their early flowering habit, and in the fact that no two seedlings seem to be identical in colour. This year I. pumila was especially precocious, for the first flower opened on March 25, and now, in the middle of April, different seedling forms are coming daily into flower. The purple forms are of every imaginable shade, while others are yellow with greenish or brown markings and some are almost white.

Can anyone, who has ever seen Tulipa Clusiana growing wild, tell us where he saw it? It is a most puzzling plant, for it is said to be wild in Batalinii and the scarlet linifolia are apparently also merely colour forms and not distinct species. As an instance of the baffling characteristics of Tulips, it may be mentioned that a collected bulb of the latter is in flower here now with two yellow and four grey-black anthers.

Tulipa praecox has been especially fine this year with its sturdy stems nearly 24 inches high and its deep red flowers that never lose their shape even in the brightest sunshine. I have been unable to find any variation among these plants, and a marked characteristic is the red purple colour that is always present on the lower part of the stem.

It is a pity that Tulipa saxatilis is not induced to flower more often, for it is unique in its broad, glossy green leaves and in its pale pink flowers with the broad yellow base. The secret of their cultivation seems to lie in giving them a warm position in rich, light soil, and especially in lifting the bulbs annually and in keeping them out of the ground until the renewal of growth shows that the time has come when they must be replanted.—*W. R. Dykes, Charterhouse, Godalming.*

[Photograph by W. Irving.

FIG. 73.—PRIMULA MARVEN.—FLOWERS VIOLET BLUE.

the Département du Gard, in the south of France, and then so far away to the east as Chitral, while there appears to be no doubt that in Tibet there is an almost stemless form, which is at present in flower here, but which is in other respects identical with the typical form.

Moreover, a close study of the habits and form of Clusiana and stellata, when growing side by side, has suggested the possibility that these two Tulips are merely colour forms of the same species. The foliage and the bulbs are indistinguishable; the two plants flower at the same time and the blooms open wide in the sun, with their inner and outer petals held at precisely the same angles in both cases. Clusiana has its outer segments "flamed" with pinkish red, a white inner surface and a deep purple base, while stellata is yellow, with the same external red streaks and no basal blotch. To the latter I attach little importance, because apparently praestans may or may not have black shading at its base, and Fosteriana may or may not have black markings on its yellow base. As far as is known, stellata is only found near the north-west frontier of India, and, if Clusiana is wild in Chitral, it is by no means impossible that the two are merely local colour forms of the same species, in the same way that the pale yellow

THE ALPINE GARDEN.

PRIMULA MARVEN.

PRIMULA MARGINATA and its hybrids comprise a beautiful group of Alpine plants, that, apart from their flowers, are almost worth growing for their charming foliage alone. They are all quite hardy and at home in the rock garden, either planted in a rocky crevice or on a sunny ledge; this species is one of the few Primulas that increase and endure for many years.

The typical plant is a native of the Alps of Dauphiné and Piedmont, and is a very old garden plant, well known for its powdery-grey leaves, which have a wavy, golden margin. There are several beautiful forms in cultivation, two of the best known being the varieties coerulea, with large, pale blue flowers, and densiflora (also known as Dr. Stuart's variety), with smaller, darker-coloured flowers, produced in denser heads rather later than the above. Other garden forms are multiflora and grandiflora, while the best form of all is the variety Mrs. Hall Walker, which has broad, beautifully margined leaves and large lavender-blue flowers with a pale eye.

P. marginata has been used as a parent for hybridising with successful results, and P. Marven, illustrated in fig. 73, is one of the best of these hybrids. It was raised by Mr. R. Lindsay from P. marginata crossed by P. venusta, and combines the characters of the two species. The leaves are grey and powdery, but almost entire in outline, while the violet-blue flowers with white eye are often produced in trusses of a dozen or more. The illustration shows its value as a plant for the Alpine house, but it is quite hardy, and does well in the rock garden. Another hybrid (P. marginata × hirsuta) was raised by Mr. W. Boyd, of Faldonside. It has the powdery-grey leaves of the former with the red flowers of the latter. So far it has not proved amenable to cultivation at Kew. P. marginata and P. Auricula were crossed at the John Innes Institution, Merton, the result being a plant very like the typical P. marginata, with narrow crenate leaves and large lavender-blue flowers in heads on slightly drooping stems. *W. I.*

ORCHID NOTES AND GLEANINGS.

CATTLEYA MENDOZA.

A FLOWER of a very brightly coloured cross between C. Fabia (Dowiana aurea × labiata) and C. Empress Frederick (Dowiana aurea × Mossiae), named C. Mendoza, is sent by Dr. Miguel Lacroze, Bryndir, Rochampton, with whom it is flowering for the first time. The introduction of C. Dowiana aurea twice in the parentage has resulted in improving the shape of the flower, and has given breadth to the petals and broader expansion of the lip. The sepals and petals are bright rosy-mauve, and the lip, which has an undulated margin, is ruby-red, lighter towards the margins and edges of the side lobes. From the base to the centre of the lip a clearly defined series of orange-coloured lines, arranged as in C. Dowiana aurea, increase the bright effect of the colour of the sepals and petals.

LETTERS FROM SOLDIER-GARDENERS.

Sheiks Saad, Mesopotamia.
December 19, 1917.

IT may interest you to hear the results of our summer crops here. They are practically finished now, though a few Tomatos and Brinjals that survived the early frosts are still lingering on. Frost this year set in very early, following the first rains, and was particularly severe, being a record for the past three winters. Unfortunately, about 30,000 lbs. of Tomatos were partly spoiled owing to frost. Climatic conditions during the months of June, July, and August, too, were very much against us; excessive heat—we registered 133° in the shade at this place—and very rough winds did much damage to the tender foliage and flowers of Melons and Cucumbers. However, we succeeded in getting some very good Melons and Cucumbers; the largest Melon weighed 25¼ lbs., and measured 38 by 36 inches, whilst the largest Cucumber weighed 17 lbs. Approximately 84,000 lbs. of Melons, 53,000 lbs. of Cucumbers, 36,500 Bhindi, 25,000 Brinjals, and 37,000 lbs. of Tomatos have been gathered; the total weight to date, including summer and autumn crops, is 426,000 lbs., fruit and vegetables.

Autumn and winter crops are now giving good returns. These are similar to what one finds in most English gardens, such as Turnips, Carrots, Beetroots, Radishes, Lettuces, and Spinach. The last-named is an Arab variety, called by the Arabs "Silij," and is an excellent sort to grow. We have several acres under Cabbage, from which good results are expected later; this year we are trying Sutton's Giant Drumhead and Early Market Cabbages, of which the plants look very promising.

Apart from fruit and vegetable cultivation, one rarely sees anything of interest to the horti-

culturist. The Arab, apparently, does not concern himself in the other departments of horticulture, though in some of their gardens I have seen good Roses, whilst an occasional clump of Hollyhocks makes a welcome change of colour. *Edward Aldridge*

PRUNUS PISSARTII IN FRANCE

THE recent references by your correspondents to the glorious effect produced by Prunus Pissartii, when in full flower, were very interesting to me. In the large garden attached to a hôtel in Caen, which I write there is a fine, naturally grown tree of this species. As near as one can judge it is quite 25 feet high, and it has been wreathed in blossoms from the ground upwards, forming a beautiful pyramid. It has been one of my delights to pay a daily visit to and admire this fine tree, and to watch the busy bees collecting honey and pollen from its thousands of blooms. In a garden in Westmorlandshire I grow this Prunus as standard and as bushes in the shrubberies and woodlands where it flowers sparsely, although beyond an occasional thinning out of the worn-out branches it is left to grow naturally. In the more formal parts of the garden I have it planted in beds for colour effect. These plants are cut down each year in February to one or two eyes. Many of those long, slender, rod-like growths which are the result of such treatment yield generous cultivation at the same time. *Jules Jeffery, R.F.F. France.*

NOTES FROM FRANCE.

EARLY RHODODENDRONS AT VERRIÈRES

A LARGE number of new Rhododendrons were collected by the late M. Philippe de Vilmorin in his gardens at Verrières le Buisson, near Paris. The smaller kinds of the Lepidorhodium section have already flowered. R. hinsecens and R. polylepis among the earliest, R. mouponense and R. spinuliferum showed their buds at the beginning of March, and were unfortunately frozen. R. sutchuenense flowered a little later, the plant was carefully covered with mats every night, and blossomed beautifully at the end of last month. This species is equal to any hybrid, not only because of its flowers, but also because of its sturdy habit and large foliage. The tiny R. intricatum was covered with its very small blue flowers; curiously enough, they have withstood morning frosts which have destroyed those of the other kinds by the end of the month. Later in March R. Keiskei, from Japan, R. rubiginosum and R. floribundum also flowered as well as R. virgatum, which is near R. ciliatum in the shape and colour of its flowers and in its well-developed calyx.

The winter frosts have spoiled the flowering buds of some forms of R. decorum, while others have not suffered. The old R. lacteum has lost a good part of its buds, as in every severe winter, but the plant itself has never suffered any harm from this cause. The fine yellow-flowered R. campylocarpum, which has stood out of doors for many years, has also lost some buds.

CUPRESSUS FORMOSENSIS.

Two young specimens of Cupressus formosensis, planted a few years ago in M. de Vilmorin's arboretum at Verrières le Buisson, near Paris, grew rapidly, promising to be highly decorative and interesting. But the hard winter of 1916-17 has tried them very severely, the tops of many branches having been killed by frost, and the foliage much damaged. The plants, however, revived in the summer, and last winter they did not appear to have suffered. It would seem that this new species is likely to succeed only in mild climates. The swelling of the branches at their junction with the main stem, noted by several writers, has also been observed on the Verrières plants. *S. Mottet.*

TREES AND SHRUBS.

EARLY-FLOWERING SHRUBS IN AN IRISH GARDEN

NEVER have early flowering trees and shrubs been more beautiful here than this season, and judging by the numerous letters in *Gard. Chron.* recently on the subject, this seems to be the case generally in the British Isles.

Mr. Watson, in his interesting remarks on p. 145, calls attention to the extreme beauty of Prunus subhirtella. The illustration in fig. 74 shows a bush of this Prunus in full flower here on March 17. Here it is the most beautiful object in the garden. P. Pissartii also calls for remark, has season has been much earlier in flower here than seems to have been the case in England. I noticed the first blossoms on February 15, and before the end of that month the trees were a beautiful sight, especially one group, which is backed up by a dark Cedar and a Sequoia gigantea. Bullfinches are very fond of the buds of this Prunus, and often attack them before the end of December. Where this lovely Plum fails to flower freely, the cause may more often than not be laid to this destructive bird. Prunus triloba also has been splendid this year, but its flowering was over by the first week in April. A small group of Cerasus Watereri, set in the grass, is the prettiest sight we have here at present (April 8), but the prodigal manner in which this Cherry flowers every year has a dwarfing effect on its growth. Cerasus J. H. Veitch is, on the contrary, growing freely; it is later in flowering than C. Watereri, and this year its branches are thickly studded with flower-buds. Rhododendron arboreum having this season escaped severe spring frosts, which often destroy the whole crop of half-expanded trusses during March, is making a fine display. The huge bushes are masses of glowing colour. A bed of Erica carnea has been a beautiful sight since the middle of January. This is the earliest warm colouring we get here, and it provides a welcome contrast to the yellows and whites which predominate amongst the earliest flowers.

A good effect is created by bushes of Pieris japonica planted amongst the Heaths. This shrub also flowered extra well this season, due no doubt to the very late spring of last year.

FIG. 74.—PRUNUS SUBHIRTELLA IN LORD BESSBOROUGH'S GARDENS, PILTOWN, CO. KILKENNY.

Fig. 74.—PRUNUS SUBHIRTELLA IN LORD BESSBOROUGH'S GARDENS, PILTOWN, CO. KILKENNY.

which kept dormant the tender young growths until all danger of spring frosts was past. These young growths, by the way, give as pretty an effect as another crop of flowers, their reddish bronze colouring being very conspicuous against the dark green of the older foliage. Amelanchier canadensis—the Snowy Mespilus—is at its very best just now, and entirely justifies its popular name. One standard tree in particular, over 17 feet high, is a mass of snow white blossom. Exochorda grandiflora, the Pearl Bush, is flowering remarkably early this season, the milk white racemes being already displayed on one bush in a sheltered corner. Magnolia stellata is past its best, but M. conspicua, thickly studded with flowers, is still a beautiful object. The male form of Skimmia japonica (Fortunei) has been wonder

fully in flower since the end of February. The blooms have a delicious perfume, something like that of Lily-of-the-Valley. A tender shrub, close by, is only now opening its first flowers, but it is bright with last season's berries. So far as can be judged at present, later flowering trees and shrubs will be no less beautiful this season than the earlier ones. *T. E. Tomalin, Bessborough, Kilkenny.*

BULB GARDEN.

GLADIOLUS BYZANTINUS.

FEW Gladioli are sufficiently hardy to withstand an average winter in the North. Of the hardier species and forms there is none known to me so hardy as Gladiolus byzantinus. It is rather hardier than G. communis, which comes next in point of endurance. G. segetum, which I grew for a few years before it succumbed to a hard winter, is next. I consider, but G. armeniacum, sent out as hardy, is not so in the North, as a rule. G. byzantinus lacks the imposing beauty of the hybrids, but is worth growing as a border plant or in the wild garden. The flowers are of a bright red, tinged with violet or magenta, and are often slightly pencilled with white in the interior. The plant grows about 2 or 3 feet high, and succeeds in any good garden soil, but needs a well-drained position. The flowers appear about June or July. *S. Arnott.*

NOTES FROM AMERICA.

AMERICAN RED OAKS.

IN the issue of February 16, p. 65, Dr. Hemsley gave merited praise to the American Red Oaks, especially mentioning Quercus coccinea. Possibly a word from the native woods where these species grow may prove of interest.

We American arboriculturists are very proud of the American Oaks, of which there are many. Dr. Sargent, in *Manual of the Trees of North America*, names 47 species, and this may be considered an abbreviated count. Many of these Oaks have value as ornamental trees, and several of them must be rated as species of high merit. Several of these are locally known as Red Oaks, though Quercus coccinea is almost always called the Scarlet Oak.

The species to which the vernacular name of Red Oak is pre-eminently assigned is Q. rubra. This is a widely distributed tree, ranging from Nova Scotia southward and westward to Virginia and Tennessee, and growing abundantly in most parts of that territory. It is a beautiful tree, and is extensively used in park planting. Further south and west the name Red Oak is given to Q. texana; and another species, distinguished as Q. pagodaefolia, growing in the south-eastern States, sometimes takes the same name.

Practically all the Oaks have showy red foliage after frost, the foliage being retained late into the winter. Several species carry their leaves through the winter, releasing them only when the new buds break in the late spring season. The most brilliant colours usually show on the Pin Oak (Q. palustris) and on the Scarlet Oak (Q. coccinea), but Q. Catesbaei and the Bur Oak (Q. macrocarpa), though displaying duller hues, are equally agreeable to the eye, especially in large masses in the open.

Several of these species are propagated by American nurserymen and widely used by planters and landscape gardeners. The Pin Oak (Q. palustris) has been somewhat extensively planted as a street tree. The Scarlet Oak, Q. coccinea, also makes a good tree for village streets and park avenues. *Frank A. Waugh, Massachusetts Agricultural College, Amherst, Massachusetts, U.S.A.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

POTATOS.—The planting of late varieties of Potatos should be completed as soon as possible. Early Potatos growing in pits or frames should have plenty of air and be protected in severe weather by covering the glass with mats or other suitable material. Very little watering is necessary: moisture is best supplied by removing the lights during a warm, steady rain.

ONIONS.—Onions raised from seed sown and treated as advised in previous calendars should be ready for planting out on ground that has been previously well prepared. Lightly fork the surface soil when the weather is favourable, and sprinkle it with wood ash and a little soot. The plants may be hardened before planting them by removing the lights altogether during fine weather. Make the surface firm, and in planting do not disturb the roots more than is necessary. Allow a space of 15 inches between the rows and 6 inches to 1 foot between the plants in the rows. Plant firmly, and not too deeply; water the roots in dry weather, and syringe the plants overhead for a few days after planting until they are established. Careful attention during the early stages of their growth and subsequent high culture have much influence in increasing the size of the bulbs and the weight of the crop.

SALSIFY AND SCORZONERA. These two root crops require similar treatment to Parsnips. A few rows of each kind may be sown towards the end of the present month in deeply dug ground. These crops may follow Celery; the seed should be sown in drills made 15 inches apart and the seedlings eventually thinned to about 8 inches apart in the rows. In the case of stiff land that has not been deeply worked, holes should be bored as for Parsnips, filling the holes with fine, light soil, and sowing two or three seeds at each station.

SEED-SOWING.—Successional sowings of Broad Beans and Peas should be made, according to the demand, and stakes placed to those sown earlier. Cos Lettuces, Cabbages and Cauliflowers, Scotch and all other Kales, Savoys and all varieties of Broccoli should be sown now. Reserve some of the Savoy seed to make another sowing a fortnight later. Turnips Early Milan and Snowball, Vegetable Marrows, ridge Cucumbers, Spinach and Radishes may also be sown. Lettuces intended to succeed those planted in frames should be planted forthwith. To have a constant supply of young Lettuce plants sow a little seed once a fortnight up to the end of June. Brussels Sprouts sown early require transplanting at 4 inches apart in a sheltered situation.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs DEMPSTER, Keele Hall, Newcastle, Staffordshire.

PLANTING YOUNG VINES.—If the border has been well prepared, and the soil made quite firm, it should not sink, at least to any appreciable extent, and planting may be commenced. The Vines may be breaking into growth, but there need be no fear of injury on that account if the work is carefully carried out. Everything should be in readiness for planting, so that the young fibrous roots will not be exposed to the air for long. Turn the Vines out of their pots, remove the bulk of the soil carefully from the roots, and immerse the latter in a tank of tepid water. The roots will separate quite easily, and should be spread out their full length, in various directions, in shallow holes made for their reception. Place a Bamboo cane to the Vine, and tie it to the lowest wire of the trellis. Cover the roots with fine soil, make it quite firm, and give sufficient tepid water to settle it about the roots. Manure should not be applied as a mulch to newly-planted Vines, but a little clean litter may be placed on the border to prevent rapid evaporation of soil moisture. These young Vines should develop slowly; a night temperature of 55° is suitable for the present, and 65° during the day. Afford ventilation according to the weather conditions, and, although atmospheric moisture is essential, do not make the border too wet.

STRAWBERRIES.—Where the shelves in early and successional fruit houses are filled with Strawberry plants in various stages of growth the work of ventilating and watering should be done with the greatest care, as the Peach and Nectarine trees, or vines if a vinery is used, have to be considered. During bright weather the plants should be examined twice daily for water and the syringe kept in constant use (but not when the flowers are open), as Strawberries are very liable to attacks of red spider. Liquid manure, soot water, and concentrated fertilisers are excellent stimulants for Strawberries, but they should be given in a weak state to plants swelling their berries. Both feeding and syringing should be discontinued directly the fruits commence to colour, at which stage the plants should be removed to a cooler house, where there is plenty of ventilation, and exposed fully to sunshine and air, at the same time reducing the amount of water gradually. The trusses should be propped up with forked sticks to prevent injury to the stalks and fruits. When the later plants have set their fruits, thin the latter to eight or twelve, according to the vigour of the plant. Admit air freely to these successional plants. Late plants plunged in a bed of leaves, ashes, or other moisture-absorbing materials should not be disturbed until they are required for forcing. Remove the lights every morning in mild, showery weather, replacing them before nightfall, and always admitting a little air at night.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

CATTLEYA, LAELIA, AND LAELIO-CATTLEYA.—Laelia pumila (and its many varieties), L. amoena, L. Gravesiae, L.-C. Rubens, L.-C. Clive, L.-C. Cornelia, and L.-C. Epicasta, are becoming active at the roots, and some of the plants may require fresh rooting materials. When repotting, the rooting capacity of each individual plant should be taken into consideration. Some make strong, robust roots, others small and feeble ones, and this fact should guide amateurs as to the size of the pots or pans to be used. The strongest growers should, of course, be afforded the most rooting space. The smaller-growing kinds of the pumila section should be grown in well-drained, shallow pans, and suspended from the roof-rafters in the coolest part of the intermediate house, or the warmest part of the cool house. The stronger-growing hybrids from pumila, such as L.-C. Epicasta and L.-C. Cornelia, should be grown in pots on the stages in an intermediate temperature. The dwarf-growing Laelia monophylla is also developing new roots, and should be top-dressed or repotted where necessary. Well-drained, shallow pans are the best receptacles, and the plants thrive well when suspended from the roof of an intermediate house. L. monophylla is a rather difficult plant to cultivate, and requires to be very carefully watered at all times. It is essential that the roots never be allowed to become very dry, or the small pseudo-bulbs will shrivel. The flower-spikes should be removed from weak plants directly they appear. Many Cattleyas and Laelio-Cattleyas which flower during the late autumn and winter are now commencing fresh root action, and should be re-potted if necessary. These include C. bicolor, C. Leopoldii, C. velutina, and the hybrids C. Iris, C. Adula, C. Atalanta, L.-C. callistoglossa, L.-C. bletchleyensis, and L.-C. Nisa. Plants of Cattleya aurea and C. Warscewiczii are also developing new roots from the base of the last pseudo-bulb, and any that were not repotted in the autumn may be attended to now if necessary. Healthy plants of all the above-named requiring increased rooting space should be afforded larger receptacles, taking care, if the compost is in good condition, not to disturb or injure the roots more than is unavoidable. Where the roots are clinging so firmly to

the sides of the pots that the plants cannot be taken out without damaging them, the pot should be broken and removed in portions. After taking the plant from the pot, cut away the back leafless pseudo-bulbs, leaving two or three behind each leading shoot, for if these useless pseudo-bulbs are allowed to remain they will weaken the plants and necessitate the use of larger pots. Unhealthy plants in sour soil should be taken out of their pots, all decayed roots and useless pseudo-bulbs cut away, and the plants potted up afresh in receptacles only just large enough to hold them. Place them in a shady position in the house, and water with great care. Plants that have sufficient pot room, and are in a satisfactory condition at the roots, may be top-dressed only. Those with long, heavy pseudo-bulbs should be secured firmly to stakes. A suitable compost for these plants is formed of equal parts of Al fibre and Osmunda fibre, broken up rather roughly, a small quantity of Sphagnum moss, and a liberal addition of crushed crocks. Pot firmly and place the compost to within about half an inch of the rim of the pot. Plants of C. Trianæ have passed out of flower, and are starting afresh into growth. They should be dealt with in a similar manner to the plants above mentioned as soon as young roots appear from the base of the new growth.

PLANTS UNDER GLASS.

By E. Harriss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Codiæum and Dracæna.—In order that Codiæums (Crotons) may develop rich leaf colouring the plants should be grown in a warm house having a moist atmosphere. When well established they may be fully exposed to the sun in a position near the roof glass. Diluted soot-water is an excellent stimulant for both Crotons and Dracænas when the plants are well rooted, and helps to produce intense colour in the leaves. Dracænas require very similar cultural treatment to Crotons, except that they should not be exposed to bright sunshine. A little air may be admitted through the top ventilators during the forenoon on warm days, but the house should be closed early in the afternoon after spraying the plants with rain water.

Sweet Peas in Pots.—Sweet Peas which are being grown in pots or boxes for supplying cut blooms should not be unduly hastened into flower by keeping the atmosphere close. This will weaken the flower-stems and render them unsuitable for decorative work. Plenty of air should be admitted at all times. When the flower-buds appear give the roots stimulants. When in flower do not expose the plants to bright sunshine or the flowers will be scorched.

Euphorbia pulcherrima (Poinsettia).—Cuttings of Poinsettias should be inserted as soon as they are available. Grow the plants in cooler conditions than hitherto for two or three days before taking off the cuttings, which will root more readily if removed from the old plants with a "heel." Place the cuttings in a propagating case with as little delay as possible after they are inserted, to prevent the foliage from flagging, and for the same reason keep them shaded from bright sunshine. Spray the cuttings two or three times daily with lukewarm rain water. A few of the best of the old plants may be cut hard back, and, after partly shaking the old soil from the roots, repotted into 6-inch or 7-inch pots. Two or three shoots may be allowed to develop from these plants. A compost consisting of loam, leaf-mould, manure from a spent Mushroom bed, and sharp sand will form a suitable rooting medium for the final potting.

Eranthemum pulchellum.—The flowers of Eranthemum pulchellum are of a rich, bright blue, and a well grown plant in flower is a very striking object. When the old plants have finished flowering they should be cut back and the roots kept on the dry side for a week or two. After this treatment they will produce plenty of shoots suitable for cuttings if placed in a house having a warm, moist atmosphere. The cuttings may be inserted in small pots filled with a sandy compost, and the pots plunged in a hot bed in a propagating frame. When rooted, pot the plants singly in 3½-inch pots filled with a compost of fibrous loam and peat in equal parts, leaf-mould, and sharp sand. Allow them to grow steadily in a house having a moist, warm atmosphere, in a position near the roof-glass. They will need shifting eventually into 6-inch pots. Some of the old plants may be transferred to larger pots after slightly reducing the ball of roots.

Gloxinia.—Seedling Gloxinias raised from seed sown this year should be pricked out as soon as they are large enough to handle. A compost of loam, peat, leaf-soil and sand passed through a fine sieve is suitable as a rooting medium. Grow the plants on a shelf in a warm, moist house, and shade them from bright sunshine. Shift them, when ready for transference, into 3-inch pots, and again later into 5-inch pots. These plants should flower in August or September. The earliest batch of old plants should soon be showing their flower-buds, and, as they are well rooted, the roots may be given a little stimulant. When the flowers are developing, grow the plants in a cooler and drier house.

THE FLOWER GARDEN.

By R. P. Brotherston, Gardener to the Earl of Haddington, Tyninghame, East Lothian.

Winter Honeysuckles and other Shrubs.—Plants of Winter Honeysuckle should be pruned hard in order to secure strong flowering shoots for next year. Forsythias trained to walls should also be pruned severely, though they do well spur-pruned as objects of colour. They succeed perfectly as bushes, though custom has not as yet made their use in this fashion general. Purple-leaved Plums have been extra profusely flowered, and these too may be pruned, but not so drastically cut as either of the foregoing. Flowering Currants will soon be past, and a little later the knife may be freely used on them. Close pruning causes the production of very healthy shoots, which are covered with flowers in March and the annual pruning serves also to keep the shrub within due bounds. Prunus triloba and P. Davidiana are other early-flowering shrubs which should be extra well attended to at present time, and reduced if trouble is to be avoided, it left alone only to weaken them.

Calceolaria.—Plant Calceolarias now that cool days may be established before the hot sunshine of May tries them. Except in very warm districts the more tender *C. amplexicaulis* should not be planted until about the middle of May, and in cold districts not till later still. In very dry soils a mulch of rotten manure or of short grass helps to keep the soil about the roots cool and moist, which is necessary for Calceolarias to succeed.

Hydrangea.—Hydrangeas growing in tubs may be put out of doors in a sheltered spot. Long established plants which it is known have an abundance of roots will need plenty of water and liquid manure on frequent occasions, as well as slight surface dressings rich in manure. If the plants were not pruned earlier, the weak growths should be cut back or removed altogether. It is sometimes necessary to disbud the stronger shoots where it is observed that there is not space for all to mature their flower-heads.

Agapanthus umbellatus.—Plants of Agapanthus umbellatus in tubs need no longer be kept under glass. They are abundant root producers, and are all the better for being turned out of the tubs or boxes in which they are established, the ball reduced along with the roots, and restored to their receptacles. But this work is best done in the autumn. Just at present water may be given with much caution until new growth develops, when the profuse application of manure water is good for them. There are two forms of this plant, one producing flower-heads many times larger than the common form, the white variety being also larger, but not to the same degree. They are easy to reproduce from seeds, which are best sown as soon as they are ripe and the seedlings grown rapidly on by frequent re-pottings. I also grow them in flower borders, but as a rule do not replant them until the flower-heads begin to push. In an airy structure they usually require no water till the above stage is reached, and, once re-established in the soil, no further attention is needed all the summer.

THE HARDY FRUIT GARDEN.

By Jas Hudson, Head Gardener at Gunnersbury House, Acton, W.

Regrafting Old Trees.—The grafting of old fruit trees may still be done where the growths are not too much advanced. The present is the best time to regraft trees on walls that face east or north. No time should be lost in taking off the scions if this has not yet been done. Select a suitable day for the work and do it as expeditiously as possible.

Trees Tied to Stakes.—Before the season is far advanced make an examination of the trees tied to stakes. The stake may be solid and secure in the ground, and the tie also satisfactory, but the string may be cutting the wood and need renewing. Short pieces of old rubber hose placed between the stake and the tree are useful in preventing damage to the bark.

THE APIARY.

By Chloris

Feeding Bees.—With the great shortage of sugar, it is difficult to advise how best to meet the situation, for, let it be remembered, more bees die of starvation during April and May than during any months of the year. When bees are found dead in the hives with heads deep in the cells, their death is due to lack of food; yet there may be much sealed stores in the frames on the outside of the brood nest. The young beekeeper sees the bees working merrily, carrying in pollen, and thinks, in consequence, that all is well with the colony, but he is deceived. Every day larger and larger quantities of brood are hatching, and there are more mouths to feed, and though there may be much pollen, few nectar yielding flowers are to be found. Where syrup feeding is possible, make it thin and feed slowly, not in advance of the daily wants of the colony, because cells are needed to raise brood in and not for storing food in the brood chamber. Always give warm syrup, and wrap up the feeder warmly so that the contents of the bottle may remain warm, and thus help to maintain a good temperature in the brood chamber during such inclement weather as we have experienced during the opening days of the present month. If stored food can be got from other hives, brushe the cappings of a portion of the frame and place the frame next the brood. Some beekeepers are using pink candy, adding ½ lb. of candy to ½ pint of boiling water.

Water.—The time of the year has arrived when bees require large quantities of water to raise brood successfully. Unfortunately, bees may get moisture from a contaminated source. Not long ago I saw a large quantity of bees taking their supply from the liquid around a manure heap. A friend of mine saw a hint in a paper which I thought was very good, and he had found it excellent. Take a bowl of water, on it drop some melted wax; these thin cakes or, rather, flakes of wax make excellent floats on which the bees can rest to take in a supply. Last year I advocated a raised sheet of glass to be placed over the water to protect it from the infected faeces of the bees, for "Isle of Wight" disease is often spread by this means. Further, the warmed water causes the scent of the wax to rise, and this draws the bees to the drinking place.

Fitting-up Sections.—The supply of wood for making sections is limited, and all will not be able to get sections. Where they can be procured they should be fitted up in readiness for the time of fruit blossoming. A crate usually holds 21 sections. Wet the folding joints on both sides with a brush dipped in boiling water, making a pile of the whole. When all are wetted, invert the pile, and commence folding the first soaked section. When this plan is adopted no joint will break rather than bend, as is so often the case when the wood is folded dry. It will be found best to use full sheets of foundation, for preference that which is thinnest and having a worker base. When foundation with a drone base is used for this purpose, the sealed sections never look so pleasing. As well filled sections this year should not be sold for less than 2s. 10d. to 3s. as minimum price, it will pay to take a little extra trouble with them.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed acrib to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication as referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

APPOINTMENT FOR THE ENSUING WEEK.

TUESDAY, APRIL 23—
Roy. Hort. Soc. Comms. meet. National Auricula and Prim. Soc. Annual Exhibition

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 48·6

ACTUAL TEMPERATURE:—

Bees and Fruit Production.

Expert opinion is divided on the subject of the importance of the honey bee as an agent of pollination of fruit trees. No one, of course, denies that the honey bee does visit fruit blossoms and play a part in pollination, but the extent to which it makes any difference to the fruit crop is by no means a matter of general agreement. The experiments* carried out by Mr. A. H. Hendrickson in California are therefore of considerable interest and value.

In the course of these experiments Plums of two varieties, French or Agen and Imperial, were closely studied, and careful records were kept of the fruit set under ordinary orchard conditions, in orchards well supplied with hives, and also in trees the insect visits to which were controlled by enclosing them in insect-proof mosquito netting, which enabled the experimenter in some cases to exclude all insects from the trees, and in others to introduce under the netting hives of honey bees. These experiments were supplemented by tests on the effect—as measured by the crop—of installing hives in a number of privately owned orchards.

The results of these experiments were a triumphant vindication of those who maintain that the honey bee is an active and important agent of pollination, and hence of fruit production.

In the case of Imperial, when all insects were excluded, the percentage of fruit set (to blossom formed) was 0.34—*i.e.*, about one in every 300 flowers set fruit.

In the open orchard 7.2 per cent. of blossom produced fruit. A tree of this variety enclosed with bees and a French tree within a mosquito net set 7.9, whereas when it was enclosed with bees alone and without a French tree companion it set only 3.02 per cent.

Evidently this variety (Imperial) is in a measure self-sterile, or, rather, only self fertile to a limited extent, and to this is to be ascribed the facts that in the open and in the enclosure, in both of which cases another variety of Plum was available for pollination purposes, the set of fruit was far higher than when pollen from another variety was excluded, and this in spite of the fact that bees were present.

In the case of the French (Agen) Plum, the set under average orchard conditions with bees in the vicinity—was 13.2 per cent.; when all insects were excluded it fell to 0.43 per cent. For one tree enclosed with bees under netting it rose to 19 per cent. Here, with a manifestly self-fertile variety, the effect of the bees on pollination is very evident indeed; amounting to one-third as much again as the set in the open. Similar results were obtained by introducing bees into orchards. In one case the owner found that his Jefferson Plum orchard, which had never before borne fair crops, produced a heavy crop when hives were installed in the orchard.

That there is safety in numbers is indicated by the fact that in the experimental orchard, whereas in 1916, with six colonies of bees to 180 acres, there was an average set of 3.6; in 1917, with 115 colonies of bees, the set was 13.2 per cent.—nearly a fourfold increase. A point which will naturally suggest itself to the orchardist is that no reference is contained in the Bulletin to other insect agents of pollination. But, after all, although we could have wished for evidence on this head, the important fact is that the honey bee is an invaluable fruit-producer; and a particularly fruitful friend of the grower in those years when flowers are not plentiful or when wild bees are scarce.

Finally, these experiments are of great interest in another direction. Artificial pollination tests had indicated that the variety Imperial is self-sterile, and yet, as we have already seen, this variety when enclosed with bees under mosquito netting set fruit to the extent of 3.02 per cent. of blossom produced. Evidently, therefore, either self-sterility is a variable phenomenon—apparent in one season and not in another—or bees are better manipulators of pollination experiments than are human beings, and indeed the delicate persistence of the bee may well make it a better agent of pollination than the average heavy-handed human being. But, on the other hand, evidence exists in the case of Apples indicating that self-sterility may be not absolute, but dependent on the season or state of the tree, certain Apples appearing to be self-sterile three years out of five and self-fertile in the other two.

It is to be hoped that, at all events in those districts from which Isle of Wight disease is absent, fruit growers will install or increase the number of their hives, for at the present time every means of increasing supplies of fruit need to be taken.

* *The Common Honey Bee as an Agent in Pomal Pollination.* By A. H. Hendrickson. Bulletin 291, University of California publications, 1918.

ROYAL HORTICULTURAL SOCIETY'S MEETINGS.—It having been represented to the President and Council of the Royal Horticultural Society that altered railway services render it necessary for exhibitors to commence packing at 5.30 p.m. in order to secure their evening trains home, consent has been given them to commence packing their exhibits at that time, and the meetings will be closed at 5.30 p.m. until further notice.

FLOWERS IN SEASON.—We have received choice blooms of Rose Maréchal Niel from Mr. J. BATES, Meaford Gardens, Stone, Staffordshire. The blooms were gathered from a tree which has occupied its present position, in a late Peach house, for forty-seven years. The trunk is 15 feet high, with a girth of 5 inches.

NATIONAL FRUIT GROWERS' FEDERATION.—The Fruit Growers' Conference, which took place in February last at the London Guildhall, decided to constitute a committee for the purpose of carrying into effect the resolutions agreed to. The first meeting of the committee took place on Friday, the 12th inst., at the Tavistock Hotel, Covent Garden. There were present: Alderman MOORE, Mr. STANLEY MACHIN (representing the Fruiterers' Company), Col. HONEYBALL, Mr. G. W. LEAK (official representative of the National Fruit Growers' Federation), Mr. DUNCOMBE GIBBS (secretary of the Federation), and numerous delegates from the Associations affiliated to the Federation. Alderman MOORE was elected chairman. It was decided to invite the National Farmers' Union (Fruit Section) to nominate two representatives. The secretaryship was offered to Mr. DUNCOMBE GIBBS, but he was unable to accept the post owing to pressure of work, and Mr. W. P. SEABROOK was appointed. Various sub-committees were appointed to deal with the subjects upon which resolutions were passed at the Conference. The Advisory Committee to the Board of Agriculture was constituted as follows: Messrs. G. F. GLENNY (Wisbech), W. COLTHUP (Kent), L. OAKES (Pershore), W. G. LORIOT (Middlesex), A. MARSHALL (Guernsey), E. S. WARWICK (Swanwick), with Mr. STANLEY MACHIN. The sub-committee to deal with the question of pulping and drying, bottling and canning factories, is composed entirely of West Midland growers: Messrs. HOPWOOD, WHITTLEY, DUNCOMBE GIBBS (Pershore), and Mr. F. MAY (Cheltenham). The committee is to be known as "The Guildhall Conference Committee" (being a Joint Committee of the Worshipful Company of Fruiterers and the National Fruit Growers' Federation).

FLUE DUST AS A FERTILISER.—The fact that flue dust from blast furnaces contains potash, and is of great value as a fertiliser, has led many people to suppose that flue dust obtained from destructors, boilers, and factory furnaces would also be of value for application to the soil. This, according to information on the subject given in Leaflet No. 23, issued by the Board of Agriculture, is not the case.

PRICES FOR ONIONS.—The attention of growers of Onions is drawn by the Food Production Department to the following announcement with respect to the 1918 crop: "In view of high freights and restrictions in shipping it is extremely important that the home production of Onions should be increased very largely and up to the fullest extent which the supply of seed will allow. In the notice issued by the Department on March 7 it was stated that the Ministry of Food had fixed prices for Onions. The statement should have read as follows: The Ministry of Food announces that in the event of its becoming necessary to fix any maximum growers' prices for the British Onion crop of 1918, the prices will not be less than those indicated in the following scale":—Early autumn (up to November 1), £15, f.o.r., f.o.b.:

late autumn. November 1 to January 1, £16 10s., f.o.r., f.o.b.; winter and spring (after January 1), £18, f.o.r., f.o.b.

POTATOS (CORKY SCAB) SUSPENSION ORDER OF 1918.—By a recent Order issued by the Board of Agriculture "the operation of the Potatos (Corky Scab) Order of 1914 is suspended until such date as the Board of Agriculture and Fisheries shall by Order direct; provided that such suspension shall not affect the previous operation of the Order hereby suspended or anything duly done or suffered under that Order or any right, privilege, obligation or liability acquired, accrued, or incurred under that Order, or affecting any penalty incurred in respect of any offence committed against that Order, or affecting any investigation, proceeding or remedy in respect of any such right, privilege, obligation, liability, or penalty as aforesaid, and any such investigation, proceeding or remedy may be instituted, continued or enforced, and any such penalty may be imposed as if this Order had not been made." This, after being in force for three years, Corky Scab Spring Sprout [illegible] terminates on May 1, 1918, and will not be left to itself. This will not [illegible] difference to the Order [illegible] interest [illegible] Guernsey Milk or the West Devon [illegible] Board of Agriculture and Fisheries [illegible] to find out the general distribution of this disease. At the time the Order [illegible] America, Canada [illegible] ability of the introduction of this disease into the States, where [illegible] existed. They had forbidden [illegible] Potato crops to West Devon, but no effort was made to get them to grow [illegible] of the Potatos were [illegible] but [illegible] was accepted by the Scotch Agricultural Department, and the Potatos were free from Wart Disease and had been grown at least for [illegible] Owing to the [illegible] Potatos [illegible] Scotland [illegible] finding out the exact [illegible] [illegible] and [illegible] [illegible] [illegible]

ON INCREASED FOOD PRODUCTION.

LEEKS.

IN reply to *G. H. H. W.* (p. 156), my article on Leeks was intended for those who wish to have this vegetable during the autumn and winter, and I venture to say that the produce of one well-grown row would equal that of five or six rows grown as *G. H. H. W.* suggests. Surely we cannot put our heated greenhouses and frames to better purpose than forwarding vegetables for use during the ensuing season—indeed, we are urged to do so. *G. H. H. W.* says: "The Leek requires good cultivation, but there is no need for coddling the plant." I agree with him, but during the early months of the year the plants must be protected if good produce is required. *R. W. Thatcher.*

—— Mr. Thatcher's advice on p. 104 is excellent, where there is the labour to carry it out. Mr. Turner (p. 154) advises sowing out-of-doors in the autumn and transplanting in the spring, which is an excellent method. Mr. Scarlett (p. 153) says: "To plant Leeks in holes 8 or 9 inches deep is utter folly." I disagree with him. The method followed in these gardens is as follows: The Leeks are sown out-of-doors about the end of March, and left in the seed-bed until they are ready for transplanting, when holes are made in previously prepared ground about 12 inches deep and 2½ inches in diameter. The Leeks are then simply dropped in the holes and watered, no soil being added, the subsequent treatment being the same as advocated by *G. H. H. W.* (p. 136). By this method labour is reduced to a minimum, as earthing up is not required. Between two and three thousand Leeks are grown annually in these gardens, and the plants would do credit to any exhibition. A large number had stems from 10 to 12 inches in length, perfectly bleached and with a diameter of 3 inches; a few were 14 inches in length. *G. H. Shoubridge, Burton Gardens, Devon.*

FRENCH BEANS IN COLD FRAMES.

ONE of the best methods of producing French Beans at their best is to sow two seeds at once in each 60-sized pot, raise the plants in heat, harden them off in a cool house, and finally plant them singly in properly prepared cold frames, in rows 20 to 24 inches apart and 10 to 12 inches from plant to plant. About 15 inches of soil should be placed on the top of 4 inches of decayed manure, and the plants set about 15 to 18 inches from the glass. A ridge of finely sifted cinder ashes placed around the inside of the frame will ward off slugs.

Syringe the plants freely on fine days and cover the lights at night when the weather is cold. Place a stick to each plant and pinch out the point of the shoot immediately it is seen above the seed leaves.

Heavy crops may be had in this way much in advance of those sown in the open, and of much superior quality. We adopt this system both for early crops and also for late supplies in autumn. Nothing is gained by crowding the plants. When in full bearing, liberal supplies of water and liquid manure should be given to the roots, and the foliage kept well syringed with tepid water on fine days, to ward off attacks of red spider. We rely on the two varieties Canadian Wonder and Ne Plus Ultra for frame cultivation. *E. Beckett.*

ALLOTMENTS AT CHESTER.

WITH a view to stimulating allotment holders to produce the maximum amount of food from their allotments, the Chester Paxton Society has offered prizes and cultural certificates for the best kept and heaviest cropped allotments in the district. A panel of practical gardeners, who are members of the society, has been formed for the purpose of giving practical advice to local allotment holders.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

FEEDING PIGS FROM SMALL GARDENS (see p. 150).—When I spoke of boarding the floor of a pig-sty, it was merely to point out one method whereby a sty may be kept clean in spite of dung, urine, and any propensity for grubbing. Our pig houses were mostly built of stone, and paved with water-polished pebbles. A wooden house, or even a large hogshead wooden barrel could serve as a sty for a small pig or two. Old herring boats, turned upside down, were used by some. Paving a sty could not be considered cruelty to the pig. We never ringed their noses, nor pared off the rim of the snout to prevent grubbing, as I have seen pigs treated in Surrey. I quite agree with Mr. Jenkins (p. 150) that young pigs that are well fed give no trouble by grubbing. In my young days we had several big breeding sows, as well as a boar, always on the premises. One cannot gauge the antics of these big animals, as the old instinct will arise at various periods of their career. Breeding sows should not be too highly fed after the young brood or litter has been weaned; nor should they be made too fat just before they litter. *J. F.*

—— From the remarks (p. 150) by *J. F.* I am convinced that he was not writing on present-day opportunities, but was thinking of times gone by. Such writings are misleading to present day would-be keepers of pigs, and thus my note, p. 141. We have to adapt ourselves to producing food quite of a different kind to that of thirty years ago, and under different circumstances. As a farmer I know the value of pigs and pig food. *E. Molyneux.*

THE SEED OUTLOOK.—The Seeds Advisory Committee of this Department is agreed that this country will be well advised to follow the example of the United States in reducing, as far as possible, the number of varieties of seeds which the trade has hitherto handled. In view of the considerable increase in the demand for seeds of food crops, both in the United Kingdom and in other seed-growing countries, and of the difficulties under which all seed-growers are at present working owing to the shortage of labour, it seems desirable to concentrate on those food crop seeds which are of outstanding importance and for which the demand is large and steady. Not only will a temporary reduction in the number of varieties on sale simplify field work in planting, harvesting, and in the care which has to be taken to isolate properly in order to avoid crossing, but it will reduce office work at a time when the demands upon man-power are so insistent. The Department will be glad, therefore, if seedsmen, when arranging contracts for seed for next season, will cut down their requirements to staple varieties and avoid asking for fancy sorts to be grown. The most urgent need of our country at present is that an adequate supply of food should be provided, and the Department feels confident that seedsmen will willingly co-operate in meeting this essential need by concentrating their efforts on the distribution of seeds of only those varieties which really matter and leaving the fancy sorts for happier times. *Lawrence Weaver, Controller of Supplies, Food Production Department, 72, Victoria Street, London, S.W. 1.*

SCARCITY OF PEAR BLOOM.—The fruit prospects this year so far as bloom is concerned are most promising in this locality, with the one exception of Pears. I never remember seeing less bloom on Pear trees, which is partly accounted for by the heavy crops last season, but not entirely, as many trees which carried very few fruits last year, and were due to fruit heavily this, are equally bare of bloom. In these gardens the only Pear trees which give a fair promise for fruiting are two that were newly planted fifteen months ago. It will be interesting to learn from other correspondents in various parts of the country what are their prospects with regard to Pears. It is surprising to see the wealth of bloom on nearly every Plum and Damson tree, even in the case of those that were borne down with fruit last year. *Edwin Beckett, Aldenham House Gardens, Elstree, Hertfordshire.*

THE WEATHER AND GHENT QUINQUENNIAL, 1903.—The keen wind and snow of the present week call to mind vividly the weather of the same time in April, 1903, which resulted in the destruction of large quantities of fruit crops all over Europe. The sea was very rough crossing to the Ghent Quinquennial Exhibition, but there was no indication of the severe weather to follow; indeed, the fine bed of Norma Hyacinths in the hotel courtyard at Ghent was perfect at night. In the morning they were under snow. The weather got colder, and the British members of the jury, waiting in evening dress to receive King Leopold, who at last arrived with his escort covered with snow, could heartily endorse His Majesty's remark to Count Oswald de Kerchove on entering the building: "My dear Count, you are indeed a magician—by your agency I have passed in a moment from the rigours of the North Pole to the splendours of the tropics" (See *Gard. Chron.*, April 25, 1903, p. 264.) *J. O'Brien.*

JERUSALEM ARTICHOKE.—A call has been made to suggest an English name for this vegetable. But can we do better than adopt the somewhat universal name, "Topinambour," which could hardly be confused with any other name. Vilmorin gives the following list of synonyms: A. du Canada, A. de Jerusalem, A. de terre, Crompire, Poire de terre, Soleil vivace, Tertiffe, Topinamboux. English, Jerusalem Artichoke; German, Erdapfel, Erdbirne; (in Austria, I think, Topinambour); Flemish, Aardpeer; Danish, Jordskokken; Swedish, Jordarts koche; Italian, Girasole del Canada, Tartufoli; Spanish, Namara, Pataca; Portuguese, Topinambor. Batata Cravalha; Russian, Topinambour; Polish, Topinambur. Another use for "Artichaux de Jerusalem" in France is for the squash or custard marrows (Patisson), and guests sometimes look incredulous when we tell them that they are eating Jerusalem Artichokes served in this manner. *H. E. D.*

—— Mr. Vicary Gibbs disbelieves in the derivation of this name from the Italian "Girasole." That the Helianthus which produces the tubers in question is known in Italy, like all other Sunflowers, by the name of "Girasole," "Turn as the sun," there is no doubt whatever. The white tuber itself is known by local names in different parts of Italy, but I have commonly heard it called "Topinamburo" by gardeners in Southern Italy. I agree, however, that it could never have come to England from Italy as "Girasole Artiocco." In the first place, there is no such word as "artiocco." The dictionaries give "artichiocco" as being occasionally heard, instead of the universal term for the Globe Artichoke, which is "Carciofo." Furthermore, Italians, even the most ignorant, never compare a Helianthus with a Cynara. The latter is far commoner than in England; in fact it is a staple Italian vegetable, and in the drier parts of the South its wild form infests ill-cultivated fields and ornaments them with its magnificent purple blooms. I will make enquiry, and let you have authoritative information as to the use of "Girasole" for the Helianthus tuber. *Charles Lacaita, 13, Chester Square, S.W.*

—— In the issue for April 6 Mr. J. Murison replies to my letter to you on p. 140 on this subject. It is a pity that he did not do me the honour of carefully reading my letter before replying—he would not then have misquoted me as he does. He writes: "Your correspondent also states that 'girasole' has never been used by Italians. This is not correct." Of course I never said anything of the kind; I said: "I doubt if any evidence can be produced that Italians have ever called *this vegetable* 'girasole'"—a very different proposition. Etymology is a matter for historical investigation, not for ingenious guessing. What is wanted is evidence that when this plant was first introduced from America some 200 or more years ago it came to England by a roundabout route through Italy, and was introduced to us by Italians under the name "girasole." A Plant Dictionary, published 1870, giving the name "girasole tuberoso," as quoted by Mr. Murison, is valueless for this purpose. *Vicary Gibbs.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 21.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs R. Ashworth, D. A. Cowan, J. Cypher, A. G. Ellwood, J. Howes, A. J. Keeling, J. Lupton, D. McLeod, J. McNab, W. Shackleton, H. Thorp, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Cattleya Brenda nobilior, *Brasso-Cattleya Leeana* (*B.-C. Lady Wigan* × *Thorntonii*), and *Odontoglossum Samuel Gratrix*, from S. GRATRIX, Esq.

Odontioda Evansiæ, from R. ASHWORTH, Esq.

Dendrobium nobile King George, from H. H. BOLTON, Esq.

Cattleya Clotha Leeana Triumph Grand Monarch × *Enid Majestic*, a Silver Medal was also awarded, from W. R. LEE, Esq.

AWARDS OF MERIT.

Dendrobium chrysotoxum Percy Ashworth, *D. Lady Colman West Point var.*, *Cattleya Enid Gratrixiæ*, and *Odontoglossum Windsor*, from S. GRATRIX, Esq.

Odontioda crispo Harrysonii Georgius Rex, from R. ASHWORTH, Esq.

Laelia-Cattleya Eunice alba (*L. anceps alba* × *C. chocoensis alba*), from Messrs. J. AND A. MCBEAN.

APRIL 4.—*Committee present:* Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. A. Cowan, J. Cypher, A. G. Ellwood, J. Howes, A. J. Keeling, D. McLeod, J. McNab, W. Shackleton, H. Thorpe, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Laelio-Cattleya West Point Pet (*L. C. Hletchi leycesiana* × *C. Empress Fredericki*), *Brasso-Cattleya Apollo Enigma*, *Cattleya Interstella alba magnifica*, *Odontioda Red Cross*, *O. Exquisita*, and *O. Coronation West Point var.*, from S. GRATRIX, Esq.

Odontioda Miss Ada Bradshawiæ × *Odontioda*), flower with brilliant crimson markings, from F. SMITH, Esq.

AWARDS OF MERIT.

Odontoglossum crispum Lord Morley, *O. Excoriator*, *Lycaste Skinneri Fairy Gem*, from S. GRATRIX, Esq.

Laelio-Cattleya Mrs. Temple Ashland's var. (*Brasso-Cattleya Joan* (*B.-C. Mary Gratrix* × *C. Octave Doin*), and *Brasso-Cattleya Langleyensis Warburtonii*, from R. ASHWORTH, Esq.

Odontioda Brewii Highfield var., from Mr. W. SHACKLETON.

NATIONAL CHRYSANTHEMUM.

APRIL 15.—A meeting of the executive committee of the National Chrysanthemum Society was held on this date at Carr's Restaurant, Strand, Mr. D. B. Crane presiding. The schedule for the current year was submitted, and is, in the main, the same as that for last year.

A proposition that the Society should join with the Finchley Chrysanthemum Society in holding an early flowering Chrysanthemum display on September 23 next, in conjunction with that society's autumn exhibition, was agreed to. It was proposed to give prizes in classes for seven vases of blooms, three vases of blooms, seven vases of disbudded blooms, and three vases of disbudded blooms respectively. Three prizes will be given in each class.

The members of the Floral Committee will meet on the same occasion.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

APRIL 8.—The monthly meeting of this Society was held at the R.H.S. Hall, on Monday, the 8th inst., Mr. Chas. H. Curtis presiding.

Five new members were elected. Five members were allowed to withdraw interest amounting to £13 11s. 10d., and three members over the age of 70 years withdrew from their deposits sums amounting to £114 18s. 4d.

The sick pay on the private side amounted to £31 4s. 7d., and the State section £18 5s. 10d., and maternity claims to £6.

The trustees stated that they had invested a further sum of £500 in War Bonds and the Committee empowered them to invest a further £300 before the next meeting.

CROPS AND STOCK ON THE HOME FARM.

EWES AND LAMBS.

TAKEN as a whole, sheep of the Hampshire Down breed have done very well in their lambing season. It is perhaps the most popular of all breeds for close folding—which is the main point to consider on an arable farm, where so much depends upon the sheep dressing the land to ensure satisfactory corn, hay and root crops. The weather has, on the whole, been favourable, especially during January and February, which are usually the most important months for lambing. There is a fair proportion of twin lambs; in fact, quite enough, considering the scarcity of cake for feeding. The deaths among ewes are few, and among lambs a trifle higher than usual. Barren ewes are more numerous than usual. Where these are above age and useless for further breeding, they should, if in a fleshy condition, be sent to the butcher at once as mutton is in much request, and fetches a good price when the quality is of the best.

Fortunately, green foods, including Turnips, Swedes, Rape, and Kale, are plentiful, although the plants are fast running to seed owing to the warm weather of March. Fortunately, Rye and Italian Rye grass are growing rapidly, and, with these foods and a plentiful supply of Mangold, the food outlook for the sheep farmer is promising. As dry food for suckling ewes and lambs nothing is equal to good Sainfoin hay. Pea chaff, malt dust, Palm kernel, rice meal and other foods as are available. Lambs thrive well upon a good supply of green food, but as well, of course, as what they could be given if the cost of Linseed cake and other concentrated foods, but as fat lambs are not required what loss there is in this is compensated by a saving in expensive food. Purchasing Linseed cake at £20 per ton is a serious matter.

To the arable sheep farmer there is still another side to the question in the shortage of concentrated foods. I allude to the loss of weight in the corn crops by the feeding of sheep on light arable land. With the penning system on light land the sheep provide manure which stimulate such crops as Oats and Barley. No farmer expects to find animal manure sufficient for his six hundred acres of arable land. In this case he has recourse to artificial manures, which at their present high price renders the expenses higher in cultivation of the cereal crops.

PIGS.

No other farm animal develops so quickly and cheaply as the pig. Pigs may be kept by the small cultivator during the summer and early autumn period, when the garden provides a certain amount of food. At that period of the year too, the weather is favourable, much more so than the three months following November, when a month plays such an important part in the welfare of young pigs, and at a time when the labour on the sty becomes scarce on the allotment or small garden.

Where reasonable facility exists for the keeping of a breeding sow—a sty with a run out in a grass orchard, or even an open yard—the phase of pig keeping should be encouraged as the more pigs that can be reared the better it is in every respect for the community at large. Young pigs are very dear, a good type of pig at seven weeks old being worth quite 30s.

For those who contemplate the keeping of a breeding sow I will briefly describe a few of the more desirable breeds. A good cross between two approved pure breeds is superior to the progeny of any first cross. Having tried many breeds, I pin my faith to a large Yorkshire White sow and a Middle White boar. One can reasonably expect a sow thus mated to rear successfully ten pigs, giving certainly three such litters in two years, occasionally more; indeed, many sows of this breed rear twelve young ones. No animal should be mated until at least eight months old, and this rule applies to pigs of both sexes.

In choosing a young sow for breeding, be sure she has fourteen teats, or certainly not fewer than twelve, because in case she should produce an extra large litter the young ones which could not claim a teat would not thrive. With young pigs there is no such thing as give and take, and the young animals adhere closely to their own sucking teats.

The advantage of crossing the Large White sow with a Middle White boar is that the progeny are stouter built, and more inclined to thicken than those of the pure Large White breed, which is more suitable for bacon, whereas the cross comes quickly to hand as porkers.

The Berkshire breed is in much favour with some persons, and where quick growing pigs of, say, four to six score are required, the Berkshire has much to recommend it. The fault with pure bred Berkshires is that the litters are too often few in number—six or eight represents a good litter. I need hardly say there are exceptions to this rule, and so me who have an extra good type of this breed obtain litters of ten, and sometimes more. The cross with a Middle White boar gives an improvement in numbers generally. A large Yorkshire White or a Black Sussex sow mated with a Berkshire boar also produces good porkers. Strange as it may appear, a white boar crossed with a black sow invariably produces pure white progeny.

For bacon the Tamworth breed of pigs is quite good; the animals are healthy, and make within a reasonable period good bacon pigs. For those who require pork only the Tamworth is not so desirable. The food required for a breeding sow is more easily obtained than for any other purpose. It is surprising what a quantity of natural food a sow finds in a grass orchard, for example—Cabbage, or leaves of any of the Brassica tribe, from June until November, provide half a living; Mangold is then available until June with the addition of Trifolium, Vetches, Parsnips, Jerusalem Artichokes, Carrots, and diseased Potatos. I prefer to keep the small Potatos for young pigs, as they form excellent food, especially when steamed, rather than boiled. If the sows can have once a day some slops with a small quantity of meal—middlings, or preferably bran—no difficulty need be experienced. Free exercise is a salient point in the welfare of a sow, especially when she is pregnant.

I am making full use of Sugar Beet for young pigs. The roots are steamed slowly, and when cooked are mashed into a jelly, mixed with a very small portion of meal and fresh separated milk, making in all appreciative food. This is the best practical use I have yet been able to make of Sugar Beet, and for this purpose it is a profitable crop to grow. The allotment-holder might easily provide a quantity of good pig food by growing this root vegetable. The leaves, too, which the plant is profusely furnished with, make desirable food. Sow the seed in drills 18 inches wide early in April, where spring frosts are not prevalent, and a fortnight later in colder districts. Thin the plants to 15 inches apart in the drills and keep them free from weeds. The roots need not be lifted until January if it is more convenient to leave them in the ground, as frost does not injure them, as they are well protected by the leaves and by the manner in which the crown of the root is buried under the soil.

E. Molyneux.

Obituary.

ALFRED PATRICK.—*Horticulture*, U.S.A., announces the death of Mr. Alfred Patrick, florist, of Auburn, New York, aged 69 years. Mr. Patrick was born in Manchester, England. He was at one time gardener to the Duke of Manchester, and was in business in South Wales for several years.

REMARKS.—Trade has fallen off during the last few days, both in London and the provinces, though the supply of all leaves had been considerably larger up to last Saturday. Dutch Tulips have increased in number, and there is a good selection of various shades at lower prices. The more favoured colour is mauve, but the supply of mauve varieties is limited. Outdoor Daffodils are now on sale. Emperor and Victoria are the best selling sorts at present. Gardenias and small quantities of Stephanotis are arriving. A few packages of French flowers are still being received, principally Pads of Spanish Iris, cut in the bud stage, arrive in good condition, but other flowers, such as Stocks and Star of Bethlehem (Allium) are well advanced before they reach the market. A few Anemones arriving are practically unsaleable. Supplies from the Channel Islands are still very irregular, and the quality is affected by the delay in transit. This is a most unsatisfactory season for flower growers in Guernsey and Scilly.

REMARKS.—Supplies of English Apples are now very limited, but a few boxes of Russets continue to arrive from France. Of English Grapes a few new season Black Hamburgh continue available. Supplies of Gros Colmar are finishing. And those of Almeria (Spanish) are also on the decrease. Forced Strawberries are not so plentiful as usual at this season of the year. The following forced vegetables are on offer:—Asparagus, Dwarf Beans, Broad Beans, Peas, New Potatos, Mushrooms, Cucumbers, Seakale, Vegetable Marrows, and English and French salads. *E. H. K. Covent Garden Market, April 17, 1918.*

DEBATING SOCIETIES.

BATH GARDENERS'. A meeting of the Bath Gardeners' Society was held on the 8th inst. Mr. F. Barter presided over a good attendance. The chairman stated that three societies—Mr. H. Sparks had resigned, and Mr. F. Mott had taken up his duties *pro tem.* Mr. C. Wall, in a paper on Onion Growing, pointed out that the Onion required a long season of growth, and being quite hardy could be sown early. By sowing under glass and transplanting in the open later, double the weight of crops is obtained on the space required for sowing direct in the open.

SOUTHAMPTON AND DISTRICT GARDENERS' Daffodils, Tulips, and other spring flowers were exhibited at the above Society's spring show. The judges awarded silver medals to Messrs. Yokes and Hartnell, and bronze medals to Messrs. Yokes, Hartnell, Clarke and Bird. Messrs. Rogers and Son, Bassett, staged a good collection of alpines and shrubs. The subject of the lecture was "The Evolution of the Daffodil," by Mr. W. F. M. Copeland. Mr. Copeland gave all the flowers he had staged to the local hospitals.

EAST ANGLIAN HORTICULTURAL. The April meeting of the above Club was held on the 10th inst., Mr. H. Perry presiding. Mr. C. H. Fox read a paper on Seed Sowing and Tran planting. He emphasised the point that the less treading of the soil after planting Potatos the better. Onions, Parsnips, Salsify, Celery, Lettuce, Turnips, Peas, Beans, Carrots, and other crops were dealt with, their sowing and subsequent treatment being also touched upon.

REPLY.

TROUT

IN reply to *J. E.*, p. 142, trout require an abundance of food in the form of water insects and plenty of water plants are necessary for the insects to feed on. He should write to the Solway Fishery Co., Dumfries, for advice. This firm supplies everything he could require. *H. E. Wootton, St. Andrew's Hospital, Dollis Hill, Willesden.*

GARDENING APPOINTMENTS.

Mr. H. H. Henness, for the past year and 10 months Gardener to G. L. Tait, Esq., Bee Court, Pangbourne, Reading, Berks, as Gardener to W. Bousey, Esq., Wood Cottage, Streatley-on-Thames, Berkshire.

Mr. W. Foord, for the past 18 months Gardener to A. Bathurst, Esq., St. Margaret's-at-Cliffe, as Gardener to Henry Beldham, Esq., Lympne Castle, near Hythe, Kent.

SCHEDULE RECEIVED.

Cottage Garden Vegetable and Bottled Fruit Show at Heath End House, near Basingstoke, on Saturday, August 24, 1918.

BOOK: *J. R. The Violet Book*, by A. and D. Allen-Brown, price 5s. 4d., post free, from our publishing department.

MEASURING LAND: *H. I. R.* The easiest way to measure the acreage of a piece of land of irregular outline is to divide it with a line into triangles, following as far as possible the configuration of the area. Measure the area of each triangle, add the totals together, and make allowances for any irregularities outside the base lines of the triangles. Needless to say, the smaller the triangles you mark out, the more accurate will your measurement be.

NAMES OF FRUITS: *W. D. and Sons*—Pears (oblong), Nec Plus Meuris; (round) Olivier de Serres.—*A. C. M.* Apple Lady Henniker. *Barnwell.* 1. Brownlee's Russet. 2. Lady Lennox.

POTATOS FOR "SEED": *A. L.* The regulation size for seed Potatos varies according to the variety, but as a rule the setts should pass through a riddle having a 2-inch mesh. Large Potatos can, of course, be cut before being sown, but naturally this increases the labour. If you wish to have full information on the subject of the Government regulations, obtain a copy of the Seed Potatos (1917) Order, which can be had through any bookseller, or from H.M. Stationery Office, Imperial House, Kingsway, W.C. 2.

TROPÆOLUM SPECIOSUM: *J. R.* In order to obtain success in growing Tropæolum speciosum it is necessary to pay careful attention to details. The ground should be deeply trenched, and the surface soil should consist of well-rotted manure, leaf-mould, and loam, passed through a coarse sieve. The roots should be planted at the beginning of November about 3 inches below the soil, and covered with a layer of finely sifted well-rotted manure. Place a few large stones in front of the bed, and a layer of smaller ones over the manure, to shade the roots and retain moisture during dry weather, and water the plants on frequent occasions. When first planting, provide some support for the tendrils to cling to. The plant is at its best rambling over a bare wall covered with galvanised netting, loosely nailed over the surface to a height of 15 or so feet, but it can also be grown over Holly hedges or Yew hedges.

VINES: *C. B.* One shoot only should be left on each spur of your vines. The first bunch usually comes opposite the fourth or fifth leaf-stalk on the lateral, and supposing the rods are 2 feet apart, three leaves may remain beyond the bunch. If the space is less than 2 feet there will only be room for two leaves to develop, and the laterals should be stopped as soon as they are from 7 to 9 inches in length. Stable manure should not be placed on the border much before mid-summer, and then only in sufficient quantity to shade the soil without preventing aeration. Up to that time depend on concentrated manures of which there are several on the market, or you may apply sulphate of ammonia at the rate of half an ounce and superphosphate 5 ounces to the square yard, repeating the dose of sulphate early in June. A good sprinkling of ashes from burnt wood or vegetable refuse would be beneficial at any time. Liquid manure may be applied, diluted in summer, before the berries commence to colour, and at a greater strength when the vines are dormant. Shading should not be necessary for healthy vines in well-constructed and amply ventilated houses, unless, possibly, for an hour or two during a very hot day when the berries are stoning.

ON CALORIES.

TO the bewilderment of the driver who had but recently learned to drive, the car, after a sudden slowing down and a jerk or two, stopped. Attempts to "start her up" again were fruitless, hitting the needle of the carburetter equally so, nor did fumbling with the magneto produce any result. Of course, the break-down occurred in the loneliest part of the road, and gloom settled on the driver. Then with an inspiration of despair, he bethought him of the petrol tank. He unscrewed the cap, and found the tank dry. The petrol had given out. It was but an affair of a minute or two to fill up and crank, and off went the car with a driver feeling very foolish, to think that he could have forgotten for a moment that a car cannot run without petrol.

This momentary lapse on the part of the driver represents the habitual state of mind of most of us with respect to ourselves as autocars. We take our three or four meals a day, and go about our daily task; and if we pay any attention at all to food, it is rather from the point of view of the pleasure it gives us than its worth as a source of energy. Yet at the present time it is all-important that we should understand that just as a gallon of petrol will serve to drive a car a certain distance and no more, so the food we eat will enable us to do a certain amount of work, and no more; that just as the petrol is consumed by burning, and in its consumption liberates energy which is put to the work of driving the car, so food—the fuel of the body—is consumed in the body by burning, and in its consumption liberates energy which is used either as heat to maintain our temperature or to do muscular and other bodily work. Furthermore, just as all engines have a certain efficiency—that is, are able to put into use a certain portion and no more of the total energy liberated by the combustion of the fuel, so the human body has a certain efficiency, and can use for doing work only a certain portion—about 30 per cent.—of the energy liberated by the combustion of the fuel supplied to it in the form of food.

These facts afford us a starting-point for finding out what is the ration of food which will enable us to work. To discover this we have to learn first the fuel value of our food, and then the amount of food which will supply the energy for doing our daily task.

To find out the energy value of food is easy. All that has to be done is to burn the food under such conditions that all the heat produced during combustion is used to warm a known weight of water. If we ascertain the temperature of the water at the beginning and at the end of the experiment, we are able to express the result thus: a given weight of food produces when burned enough energy to do the work of raising the temperature of a given weight of water so many degrees.

In order to have a unit for comparison, we agree to define our heat unit or large calory as the amount of heat required to raise the temperature of a kilogramme (2·2 lbs.) of water 1 degree Centigrade. Since heat energy may be used to do work, we are able to measure the calory in terms of work, and by this means to discover that the heat contained in a calory when transformed into work will lift 425 kilogrammes one metre—that is, 1·1 ton one foot. Furthermore, since we know that the fuel value of the foods we eat resides in the digested parts of the food, we can, by finding out the proportion of digested to undigested food, correct the fuel values by subtracting from them the values of the unused (undigested) foods. We thus get the heat values of food actually used in the body. For example, with respect to one class of food, the nitrogenous foodstuffs known as proteins, we know that, although the proteins are digested, they do not undergo complete combustion in the body; before combustion they are split into simpler substances, one of which (urea) is not used at all, but is excreted. It is, therefore, necessary to deduct from the total heat value of a protein the heat value of the urea which is split off from that protein and discarded unconsumed by the body.

Again, since it is known that the foods used by the body for heat- and energy-producing purposes are fats, carbohydrates (starch, sugar, etc.), and proteins, and since it is possible experimentally to find out the number of large calories in 1 pound of each of these substances, and to discover also how much of each of these foods is digested and consumed in the body, we can compare these foods with one another with respect to the calories they contain. For example, we find by burning tests that a given weight of fat develops 2·27 times as much heat as an equal weight of starch. We also find that in an animal the proportion of starch which actually gets into the body and is consumed and produces heat is less than the proportion of fat which is utilised by burning in the body.

In this way it has been found that the heat value of fat is upwards of twice that of starch, and that the heat value of protein is about the same as that of starch.

Evidently this knowledge is all-important from the point of view of rationing, for although from the point of view of heat production any one of these substances is efficient, they differ in efficiency to such an extent that it would require about 2¼ times as much starch as it would fat to produce the heat necessary for providing the energy for bodily work.

It will be remembered that the large calory has already been defined as the quantity of heat required to raise the temperature of 1 kilogramme (2·2lbs.) of water 1° C. This unit is too large for the present purpose of estimating human food values. So instead of the large calory we will use as our unit the little calory. This is easily done with the metric system, for 1 kilogramme is equal to 1,000 grams, and one little calory becomes, therefore, the amount of heat required to raise the temperature of one gram (about 1·30 oz.) of water 1° C.

We are thus in a position to state the number of little calories in a given weight of each of the essential foodstuffs contained in human food:—

1 lb. of pure fat yields about 4,208 calories.

1 lb. of pure protein yields about 1,856 calories.

1 lb. of pure starch yields about 1,856 calories.

The amounts of fat, protein, and carbohydrate contained in each kind of food being known as a result of many chemical analyses, it is easy to ascertain the number of calories provided to the body for use therein by a given quantity of such foods as meat, milk, Potatos, margarine, etc., which make up a meal. The following table* gives this information:—

Food.	Protein.	Fat.	Carbohydrates.	Calories.
	Per cent.	Per cent.	Per cent.	Per pound.
Beef, Veal, and Mutton (average)	14·5	16·1	—	913
Rabbit	21·5	2·5	—	504
Fish (without refuse)	18·4	4·3	—	506
Fish (rich in fat)—				
Herring	20·5	7·1	—	660
Salmon	22	12·8	—	950
Milk (20 oz. to pint)	3·3	4	5	332
Butter	1	85	—	3580
Margarine	1·2	85	—	3570
Cheese	25·2	33·7	2·4	1950
Bread (average)	9·2	1·3	53·1	1215

(To be continued.)

ON INCREASED FOOD PRODUCTION.

POTATOS.

AFTER an experience of fifty years, I know of no crop that will so well repay for high class culture as the Potato. Almost any kind of soil will grow a crop of Potatos—good, bad, or indifferent; but to grow fine crops of good quality tubers fit for exhibition and table use, the best soils are those of the old red sandstone, and the worst kinds are strong clays of a cold, tenacious character. Heavy soils should be well dug or trenched in the late autumn or winter, and at the same time a quantity of rich, well decayed farmyard manure should be added. Light soils should be prepared a short time before, or at planting time. Heavy soils require opening up, in order that the frost may pulverise them, and make them friable and mellow to receive the seed tubers, but light or sandy soils, when dug in winter, have a tendency to be too free and open, and, in consequence, do not hold moisture so well, and, should a dry summer prevail, the crops are bound to suffer.

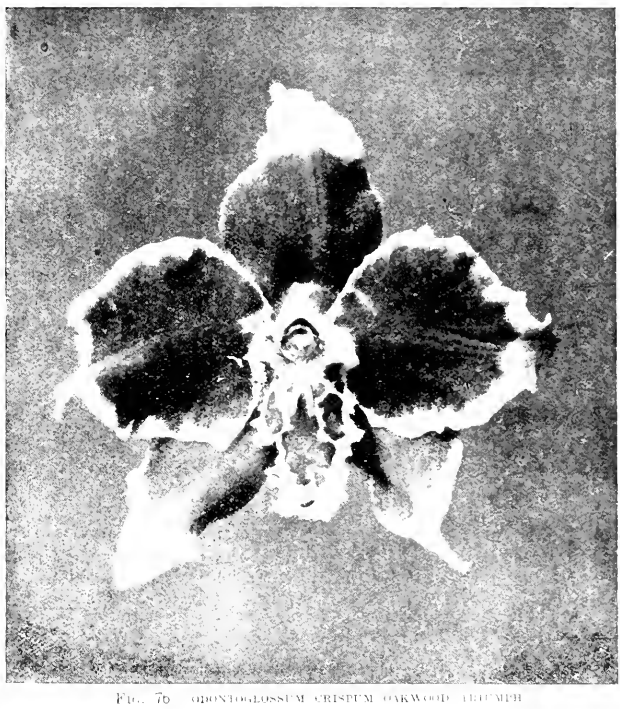

FIG. 76.—ODONTOGLOSSUM CRISPUM OAKWOOD TRIUMPH.

Whichever method of preparation is adopted, always enrich the ground with plenty of manure, and if the soil is considered deficient in lime, give a good sprinkling of lime over the surface previous to planting. If burnt lime is cheap, and not difficult to procure, apply it freely, not, however, when the manure is dug in, but in the spring, when preparations are being made for planting. Manure should always be applied some time previous to lime. Lightly forked in, lime will benefit most soils, rendering them sweet and fit for almost any kind of crop. In the case of light soils, marl may be added, and this material will as a rule make the use of farmyard manure unnecessary for a season.

Sulphate of potash is also an excellent fertiliser for Potatos. One open handful to 5 yards of running drill, or, say, 1 lb. to 30 square yards, in autumn, will generally prove a suitable dressing.

It is highly important to change the seed tubers frequently; if not every year, at least every second or third year. It is important, too, that the seed be well sprouted, and previous to planting all the side shoots should be rubbed off, leaving only one, or never more than two, strong shoots at the top. The tubers should be of medium size, and may be planted whole, with perhaps a thin portion cut off the lower end to ensure the tuber rotting, as few Potatos form when the old set remains sound and hard. Nothing is gained by close planting; especially is this true in the case of main crop varieties. The drills for early and second early varieties should be 2 feet to 2 feet 3 inches apart, and the tubers spaced 1 foot or so in the drills, whilst for late varieties, 2½ feet (in the case of extra robust varieties 3 feet) by 1½ feet should be allowed. Wide planting helps to keep the crop free from late blight disease. The ground should be deeply forked prior to planting, and a few days before planting again lightly forked, to make it fine and friable. This remark applies to heavy soils more than to light ones. The sets are usually planted either by means of a dibber or by drawing drills with a hoe, but the best way is to plant with the spade or fork, especially on heavy soils. By this extra working when planting the soil is left in a fine, open condition. Whichever method is adopted, the tubers should be set at a depth of from 4 to 5 inches, according to the nature of the soil and time of planting. If manure is applied at planting time the seed tubers must not come in direct contact with the dung. The soil should be well hoed as soon as the Potato tops can be well seen in the rows. Hoeing keeps the crop clean, and promotes good growth. Previous to earthing up, it is good practice to fork the spaces between the rows, that the soil may be loose and dry. Earthing up should be done twice, at intervals of a week or two. Draw the soil well up into sharp ridges, and do it early—as soon as the "shaws" or "haulm" are large enough to admit of the work being done properly.

I have grown as many as 50 varieties in one year, but I do not grow many nowadays. One or two sorts at the most, of each section will be quite enough for general purposes. Early varieties should be planted in March or early in April, in a well-sheltered situation. Second early varieties planted early in April will be ready to dig in August, according to the season and locality, and thus follow in succession the early sorts. Late or main crop varieties, though planted in March and April, will not mature so quickly as the second earlies, but will continue to grow till September and October. Such varieties may be planted up to the month of May, and still produce splendid crops.

All Potatos should be lifted as soon as the tubers are mature and ripe, and seed tubers should be well "greened" before storing. Seed selected in this way generally gives splendid crops, even though grown on the same ground for a number of years.

No method can surpass storing in "pits" or "clamps," with plenty of Wheat straw and soil for covering. If the clamp is well made the Potatos will keep fresh and not shrivel all through the winter, and when required for kitchen use, or for seed purposes, to be "sprouted" previous to planting, they can be depended upon to have lost little or none of their good quality. *Delta.*

ORCHID NOTES AND CLEANINGS.

ODONTOGLOSSUM CRISPUM OAKWOOD TRIUMPH.

FINE and richly blotched forms of Odontoglossum crispum were great favourites with the late Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, and the list of awards by the Orchid Committee of the Royal Horticultural Society contains the names of a dozen of his best, including the varieties O. crispum, Cooksoni, Cooksoniæ, and Leonard Perfect, for which latter a First-class Certificate was awarded May 12, 1908.

Mr. Cookson, who was one of the most successful Orchid hybridists, seeing the difficulty of importing handsome blotched forms of O. crispum, and the possibility of improving on them by home-raised seedlings of pairs of selected varieties, set to work in that direction. O. crispum Leonard Perfect, crossed with O. c. Phœbe, produced the handsome O. crispum Oakwood Triumph, which secured an Award of Merit at the Royal Horticultural Society on April 9 last. O. crispum Oakwood Triumph (see fig. 76) adheres closely to the fine form and bold markings of O. c. Leonard Perfect, but the rich ruby-red colouring on white ground is more intense and broadly expanded than in the parent variety, whose one defect of varying considerably in quality from one season to another seems to have been corrected in the offspring by greater depth of colour. It is pleasant for Mrs. Cookson and her gardener (Mr. H. J. Chapman) to watch the development of these interesting plants, in which they had a common interest with the originator.

COTTON'S "PLANTER'S MANUAL."

THE literature of fruit culture in Britain in Stuart times does not offer much of interest, the translation by Evelyn of Quintinye's classic work evidently rather overawed the native writers. Other authors such as Markham and Hartlib relied on foreign works, and were little more than translators, and it was not until Worlidge published his various books that really native works could be claimed for this period.

A few years after Worlidge's *Systema Horticulturae* was published, the *Planter's Manual* appeared, by Charles Cotton, hitherto known as a poet and for his association with Walton in the

Compleat Angler. The son of a rich landowner, he travelled in France, and became a well-known figure of his day.

The book under consideration was published in 1675, and the title-page reads "*The Planter's Manual*, being instructions for the Raising, Planting, and Cultivating all sorts of Fruit Trees, whether stone-fruits or pepin-fruits, with their Natures and Seasons. Very useful for such as are Curious in Planting and Grafting. By Charles Cotton, Esq."

The preface is worth quoting at length :—

"To the Reader.

Though this little Treatise on Fruit-Trees was only written for the private satisfaction of a very worthy Gentleman, who is exceedingly curious in the choice of his Fruits, and has great Judgement in Planting; yet having heard that Gentleman say it had given him the greatest satisfaction of any Bauble he had seen of this kind, I began to think it might not be altogether unuseful to the Publick also, and therefore sent it to the Press, which is all the excuse I can make, either for the writing or publishing of it. But I think it fit to tell you, That although the Planter who shall pursue the following Directions, may possibly find himself defeated in his expectation (especially in the more Northerly Provinces of this Kingdom) as to the precise time of his fruits' maturity, and that a Fruit planted and extended against a good Brick wall, is more proper here with us (where we have never too much sun) than an Espallier Pallisaded at some inches distance from it; yet he will infallibly find his Industry abundantly gratified in the promised effects, at a something later Season. And although the reader will here meet with several names of Fruits he peradventure never heard of before; yet we know and see, that more tender plants, as Oranges, Lemons, Citrons, etc., are yearly imported from much remoter Countries than France; and seeing that (for ought I ever heard) Fruit-Trees are no contraband commodity betwixt the Nations, I cannot conceive but that it is worth the Curiosity, pains and cost to furnish ourselves from thence with those of the greatest excellence, both for Beauty and Flavour; nor why we should not better ourselves this way by them, as altogether to be debauched by their effeminate manners, luxurious kickshaws, and fantastic fashions, by which we are already sufficiently Frenchified, and more than in the opinion of the wiser sort of men, is consistent either with the constitution, or indeed the honour of the English Nation."

From this evidence it would naturally be assumed that the work was by Cotton himself, and I held this opinion until recently, when by chance hunting for certain varieties of Cherries, I turned shortly after to a scarce French book entitled *Instructions pour le Jardin Fruitier*, when the certain resemblance led to a closer examination, which revealed the fact that Cotton's supposed work is but a translation and must therefore be deleted from his list of writings. This has not, to my knowledge, been pointed out before; indeed the *Dictionary of National Biography* refers to him as a skilled horticulturist, presumably on the strength of the work under consideration.

This being so, it will be interesting to examine the original of his translation more closely. The *Instructions* form a small duodecimo, and were first published in 1653, the author concealing his identity on the title-page by the letters M.R.T.P.D.S.M." As often the case in anonymous French writings of this period, the secret is given away in the "Privilège," and here we learn that these letters refer to M. Robert Triquet, Prieur de St. Marc. The preface furthermore informs us that Triquet was only editor, and the book was written by one François Vanlier, physician to Louis XIV. Vanlier is remembered in medicine for his advocacy of antimony and quinine as drugs, and so far did he press his ideas that his brother physicians were strongly antagonistic, and had the last word in the controversy by attributing his death to an overdose of the first-named remedy. In his early days he was physician to Maria de Medici, and is said to have had an extraordinary influence over her. This brought him into conflict with the powerful Richelieu, who promptly confined him in prison from 1631 to 1643. After his release he was appointed premier physician to Louis XIV., and as botany and medicine were in those days closely allied he took charge of the Jardin des Plantes. Here he made several remarkable innovations, among which was his substitution of anatomical lessons for the rather vague discourses on the "interior of plants" which had formerly held place. He was the first to use quinine as a drug, according to the *Bibliographie Universelle*, from which these facts are drawn.

The *Instructions* were found among his papers after his death, and by the desire of several "curious" persons were edited by Triquet and first published in 1653. A third edition appeared in 1658, which contains the additional chapter on the pruning and culture of Oranges, Lemons, Citrons, Pomegranates and Jasmins d'Espagne. In the light of this knowledge it will be seen that Cotton's preface rather cleverly detracts from definitely claiming authorship, though a casual reading would leave little doubt on the point. The plagiarisms of horticultural writers are unfortunately many, and I hope to show in a further article some others which I have traced, and which are of interest in many ways, especially to those who wish to establish dates for the introduction of fruits or plants, when it is obviously important to trace the references to their original source. *E. A. Bunyard*

NARCISSUS IRENE COPELAND.

Not many raisers have taken up the cause of the double Daffodil with any degree of seriousness, probably because double flowers are not very fashionable in these days, and the old early N. Telamonius plenus is not particularly beloved of Daffodil specialists. But a few of the newer doubles have become popular, and Mr. W. F. M. Copeland has done not a little to add to their popularity and increase their attractiveness. His new variety, Irene Copeland (see fig. 77), certainly has attractions which cannot be overlooked. It was exhibited by Mr. Copeland at the Royal Horticultural Society's meeting of April 9. This variety is the result of crossing 'Giant Leedsii' form with Sulphur Phoenix. It is a round flower, with six rows of rounded, white, and fairly flat perianth segments, and a number of pale citron cup segments, the whole making a charming flower of circular rose-like form, with a diameter of 5¾ inches. The stem often reaches a height of 20 inches, and is stiff enough to carry the blooms erect. It is particularly stout just where it joins the flower, thus obviating that neck weakness which is so great a defect in many weighty varieties. Mr. Copeland is to be congratulated upon his achievement among doubles, and it is to be hoped he has many other good things in this section in store for Daffodil lovers. *C.*

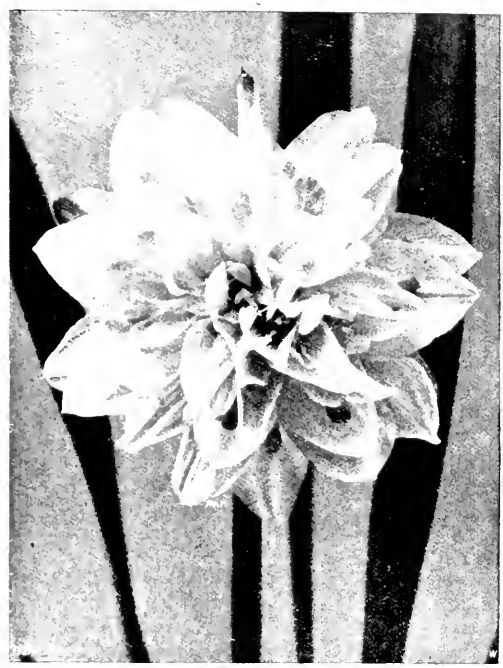

FIG. 77.—NARCISSUS IRENE COPELAND.

TREES AND SHRUBS.

AMERICAN RED OAKS

(See pp. 65, 166.)

At the present day the Red Oaks, amongst other ornamental species, are being planted in this country, somewhat to the exclusion of our native Quercus pedunculata. The Red Oak (Q. rubra) is the most widely distributed in Surrey and the surrounding counties, including Berkshire and Middlesex. The largest specimens I have seen take rank with timber trees, being 50 to 60 feet high, with a trunk 15 to 18 inches in diameter. These are on the Bagshot sands in west Surrey. The species is sparingly used as a street tree in north Surrey. In the same dis-

trict, on the old valley gravel, the Scarlet Oak (Q. coccinea) is planted in greater numbers, but the trees are younger. The largest specimens, about 35 feet high, would seem to have been planted tentatively 10 or 15 years ago; they are of beautiful, pyramidal habit, and colour up well in autumn. One is a Coronation tree. The intensity of colour varies with the individual tree when raised from seeds. One variety has been named Q. coccinea splendens, and this is very handsome. Young trees, at least, retain their leaves for several months during the winter. I was pleased to read the high praise bestowed on the Pin Oak (Q. palustris) by Mr. Frank A Waugh (p. 166). I am more enamoured of it than of Q. coccinea, whether in the green or coloured state, because of its wealth of twiggy branches, and the glossy green leaves polished on both surfaces. The leaf-stalks are long and slender, and the tree as a whole is very graceful. I know of two pyramidal trees, 40 to 45 feet high, on a Surrey common, in open parts of a wood, and they colour splendidly in autumn. All three are also being planted in Berkshire. *J. F.*

FIG. 78.—IRIS SIND-PERS.

PLANT NOTES.

IRIS SIND-PERS.

THIS is one of the most beautiful of Irises flowering in March. In the Cambridge Botanic Garden it does well in front of the houses on a bed which is well drained, and is composed largely of grit. It is a hybrid between two Juno Irises, the tall Iris sindjarensis and the stemless I. persica. The name, it may be remarked, was given by Sir Michael Foster according to his plan of taking the first syllable of each name of the parents. It was raised by C. G. van Tubergen, and is one of the best of his productions. It was described briefly by Sir Michael Foster in the *Gardeners' Chronicle* of April 15, 1899, p. 236, and his concluding remark was that "everyone who sees it will, I am sure, want to possess it." This, indeed, must be the case with anyone who has recently seen it in the Cambridge Botanic Garden, where it opened first in about the first week of March, and continued quite to the end of the month. The general effect of the flower is pale blue, but this is relieved in the case of the falls by a median line of golden-yellow, marked also by small purple dots; the standards, as in all Juno Irises, are small and reflexed. The flower measures nearly 4 inches across. The plant may be regarded as half-way between the two parents, although it is quite dwarf, not growing more than about 6 inches high, while I. sindjarensis attains at least one foot. The leaves are about 6 inches in length, and, like the flower, are intermediate in character between those of the parents. The female parent was I. sindjarensis, and compared with it the flowers are a fuller colour, but they are without the patch of colour at the apex of the fall which forms so conspicuous a feature in Iris persica, the male parent. It is much more easily grown than I. persica, for while I. persica is certain to disappear, this hybrid goes on from year to year indefinitely, and has increased very satisfactorily. *R. Irwin Lynch.*

FLORISTS' FLOWERS.

FREESIAS

AT one time, not so very long ago, the only Freesias in general cultivation were the different forms of F. refracta. The flowers were of various shades of white and yellow. The first step towards other colours in the blossoms of Freesias was the introduction of F. Armstrongii about twenty years ago. This species was sent to Kew by Mr. W. Armstrong, of Port Elizabeth, who found it wild at Humansdorp, Cape Colony. In this species the flower is a shade of rosy-lilac, deeper towards the edges, with a light-coloured throat and a patch of yellow inside. This species, and perhaps others introduced since that time, have in conjunction with the older kinds given us an entirely new race of these beautiful flowers. Now various shades of lavender, lilac, pink, yellow, and a suspicion of purple are to be found among the more recent forms. The first of these coloured kinds to be recognised by the Floral Committee of the Royal Horticultural Society was Tubergenii, said to be the result of a cross between Freesia refracta alba and F. Armstrongii. The variety was given an Award of Merit on March 6, 1906. Just over a year later, namely, on April 16, 1907, a similar award was made to Amethyst, also raised by Mr. Van Tubergen. The first British variety to gain that honour was Rose Queen, which, shown by Messrs. Barr and Sons, was given an Award of Merit on February 23, 1909. Some years previous to that, however, a delightfully coloured hybrid was raised at Kew, and attracted a good deal of attention. It still finds a place in the Kew *Hand-List of Tender Monocotyledons*, where its parentage is given as F. Armstrongii × F. refracta Leichtlinii. While the typical F. Armstrongii possessed little or no fragrance, some of the newer hybrids, owing to the influence of F. refracta, are sweetly scented. The rich yellow flowered F. aurea, for which an Award of Merit was given at the Temple Show of 1902 when shown by Messrs. R. Wallace and Co., does not occur in the Kew *Hand-List*. I am aware that there is some confusion in the white and yellow forms of Freesia, so perhaps this golden kind may be regarded as one of the varieties of F. refracta. As the coloured forms of the Armstrongii race have proved themselves as amenable to cultivation as those of the refracta tribe, we may expect to see still further improvements among them. *W. T.*

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

TOMATOS.—Give a light top-dressing of loam, a little artificial manure, and frequent applications of weak liquid manure to Tomato plants that are ripening their fruits. Maintain a temperature of 60° to 65°, with sufficient ventilation to keep the atmosphere sweet and buoyant. Stop the plants when a sufficient number of trusses have formed, and remove all side-shoots as they appear. Where it is intended to plant in borders, plants for the main crop should be ready for transferring to their fruiting quarters. Virgin loam should be used when this can be obtained, adding gritty material and a little potash. If the plants are to be grown in pots pay timely attention to their repotting until they are given their final shift, for plants that become pot-bound seldom regain their former vigour. Plants intended for out-door cultivation should be grown on carefully under glass, and hardened later in readiness for planting out in the first week in June.

CUCUMBERS.—The recent inclement weather and absence of sunshine have been unsuitable for Cucumbers, rendering the plants liable to checks unless extra care has been given in ventilating and syringing. These remarks apply especially to plants growing in pits or frames. Fresh fermenting material should be placed round the frames, and the lights covered at night by mats or other protective material. Plants growing in favourable conditions are making rapid progress, and should be given light top-dressings of rich soil before they have covered the bed with much growth. Keep the shoots thinly trained, and stop them at the second or third joint beyond the fruit, according to the space available. Sow more seeds to obtain plants for successional fruiting. Plunge the seed-pots in a mild bottom heat until the seedlings are well through the soil, when they should be placed near to the glass. Prepare fresh beds as advised in the calendar of March 23. Use tepid water for the roots and for syringing; but little syringing will be needed for a few weeks to come.

SPINACH.—Seed of this quick-growing vegetable should be sown every fortnight until the end of May, in deep, rich, friable soil. Thin the seedlings to 3 inches apart, and afterwards to 6 inches. Sow in small quantities, as during dry, hot weather the plants quickly run to seed.

CELERY.—Early Celery plants are ready for pricking out on prepared beds in frames or in boxes, the former method for preference, as then the plants are not so liable to suffer from want of water. The plants may be lifted from frames with splendid roots ready for planting out, and this is the best system of growing them where large quantities are required. Ventilate the frames carefully to harden the plants that they may receive no check when finally planted in the trenches.

THE HARDY FRUIT GARDEN.

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

DISBUDDING.—Newly-planted trees on walls should be disbudded in good time; it is better to disbud freshly-planted Peaches and Nectarines than to cut them back severely earlier in the season. In this way good fruit-bearing wood for next season will be secured, as well as short, spur-like growths, which will often set a few fruits when longer ones fail to do so. Trees so treated may not possess quite the same vigour as with a lesser number of shoots, but they will not be nearly so liable to gumming. Watch them closely for the first season, and when short, forerright shoots develop, do not rub them off, but make them into spurs. Watch for the first appearance of green fly, and syringe at once with a solution of liquid Quassia extract. The same treatment can be applied to young wall Plums and wall Cherries. Disbud young Cherry

growths at once; pinch some shoots to encourage young spurs to form where there is room for them. A free use of the finger and thumb, when the shoots are young and sappy, as a means of pruning, is much to be preferred to the use of the knife in later stages of growth. It is more quickly done, and if followed up until the growths are controlled and well regulated, there will be less likelihood of gumming or canker. Apricots, too, may be treated in the same manner. As soon as the young trees are seen to be well established, cease to water quite so liberally, or unduly sappy growths will result. The object of the fruit cultivator should be to bring these young trees into an early fruit bearing condition, rather than to produce strong, exuberant shoots.

PEAR TREES.—This season it does not appear that there will be even an average crop of Pears, and the present time forms an excellent opportunity of thinning out the spurs of Pear trees where they are overcrowded. Some varieties form spurs much more closely together than others. Espalier trained Pears are often overcrowded with weakly spurs.

THE ORCHID HOUSES

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN Bart., Gatton Park, Reigate.

LYCASTE.—Plants of Lycaste Skinneri, L. Balliae, L. Gratrixiae, L. leucantha, L. costata, L. lasioglossa, and L. lanipes develop new growth after they pass out of flower, and the necessary repotting should be done at this stage. Most Lycastes are vigorous-rooting plants and require ample pot room, also a richer and more retentive soil than many other Orchids. Ordinary flower-pots are the most suitable receptacles and for a rooting medium use a mixture consisting of three-parts good fibrous loam, with the smaller particles shaken out, and one part made up of partly decayed Oak leaves, chopped Sphagnum-moss, with a liberal quantity of crushed crocks. Specimens that are pot-bound should be shifted into pots that will be sufficiently large to accommodate them for at least two years. Others that have sufficient rooting space and with compost in good condition should not be repotted, but portions of the old rooting materials may be removed from the surface and replaced by fresh compost. Plants that are in an unsatisfactory condition at the roots, or that are growing in sour compost, should be taken out of their pots, the roots cleansed of the old materials by washing, and the plants potted afresh in small pots. Keep the crown of the plants a little below the rim of the pots in order to provide plenty of space for water, of which Lycastes require liberal supplies, except when resting. After root disturbance water should be applied with extra care until the young roots have grown freely in the new compost. It is advisable to wash the undersides of the leaves occasionally to destroy red spider, a common pest of this Orchid. The plants will thrive in the warmer part of the cool division. Dense shade is not recommended, and the house should be freely ventilated.

SOPHRONITIS GRANDIFLORA.—This Orchid is developing roots from growths which have recently flowered, and plants that require fresh rooting materials should receive attention. Shallow Orchid pans are the most suitable receptacles; they should be provided with plenty of drainage materials, and the compost should consist of Osmunda fibre or A1 fibre and Sphagnum moss. Cut the materials into short portions, as when used in a coarse state the rhizome retains the moisture too long. The plants thrive in the cool Odontoglossum house suspended from the roof, or they will grow equally well on the stage if arranged close to the roof-glass. Afford the roots plenty of water while they are active, but when the plants are at rest give only sufficient moisture to keep the pseudo bulbs plump.

SPATHOGLOTTIS.—Plants of Spathoglottis that were not repotted last year should be attended to in that respect as they start into growth. Fairly deep pans, or ordinary flower pots, form the best receptacles, and a compost similar to that recommended for Lycastes is suitable. These plants require a warm temperature, and should be well shaded during bright days. A liberal supply of water is needed by the roots, but the amount should be gradually diminished as the pseudo bulbs reach maturity, and entirely withheld for a few weeks during the winter months. The foliage should be frequently sprayed in order to destroy thrip and red spider, which sometimes attacks the under-surface of the leaves.

FRUITS UNDER GLASS.

By W. J. GUISE Gardener to MRS. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

THE ORCHARD HOUSE.—Trees of Apricot, Plum, Pear, Peach, Nectarine and Cherry growing together here in the same house have set their fruits, and all promise to produce good crops. This I attribute to the use of a little warmth in the hot-water pipes at night, which is very necessary in cold, damp districts. Two rows of pipes (flow and return) are sufficient for these fruit houses, the cost of fuel, even in these times of high prices, being very small. A temperature of 45° to 50° through the night, and 60° by day is suitable for mixed fruit houses. Air should be admitted when the thermometer registers 60°, and the amount gradually increased as the temperature rises, until it reaches 80°, for much as these trees require fresh air, they must be protected from winds and draughts. Maintain a moist atmosphere by syringing the trees twice daily with tepid water, except in dull, cold weather. Keep pot trees moist at the roots by judicious watering. When the fruit is swelling the roots may be given stimulants in a weak state twice weekly until the stoning period, and then on every other day. Weak liquid manure, guano, soot and lime water used alternately will supply all the food necessary for the proper development of both fruit and wood. Robust trees require daily attention as to regulating and pinching the shoots, not only to prevent waste of energy, but also to keep them of even growth. If the house can well be ventilated the trees can be left out. Very little aphis may be present, but it is astonishing how rapidly this pest spreads on Cherries, Plums, Peaches and Nectarines. Light attacks can be checked by spraying with Quassia Extract or dusting tobacco powder on the shoots, but badly infested houses should be fumigated, and the fumigation should be repeated if necessary. Choose a mild still night for fumigating, and let the foliage be dry. Make the house as air-tight as possible to retain the fumes.

LATE PEACHES AND NECTARINES. All the latest trees of Peach and Nectarine have set their fruits, and the syringe may be used freely on bright days. Examine the borders, and if dry afford copious supplies of clear water. Short stable manure spread over the borders will assist the trees at this stage, and prevent rapid evaporation of moisture. Disbudding and tying in, with a little thinning of the fruit, will require frequent attention, but the work must be done gradually. These late trees do not usually cast their fruit if they are properly managed, still it is advisable to make allowance by leaving sufficient for a final thinning at or near the stoning period. Even late houses must be carefully ventilated and cold draughts prevented.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

GLORIOSA SUPERBA.—The flowers of this stove climbing plant are useful for decorative purposes. Two or three plants trained thinly over the roof of the stove or any other warm house will furnish a plentiful supply of flowers through the summer and early autumn. Water carefully plants which were started into growth last month until their growth has made considerable progress. When well established the roots should be given a stimulant. Diluted liquid manure from the farmyard and soot water may be used about twice a week. Gloriosas when in active growth require plenty of warmth and a moist atmosphere. The sun's heat should be made full use of in preference to much fire-heat. Give timely attention to the training of the young growths or they will become hopelessly entangled.

RHODODENDRON INDICUM (INDIAN AZALEA). Remove the dead flowers from Indian Azaleas when their blooming is over, and repot or top dress the roots as their requirements demand. Grow the plants in a house having a warm, moist atmosphere until they have ripened their shoots. A compost of fibrous loam and peat in equal parts, some leaf-mould, and coarse sand, forms a suitable rooting medium for these plants. See that the pots are efficiently drained, and afford water with great care till the roots have become established. Examine the foliage carefully for red spider, and should there be evidence of this pest lay the plants on their sides and drench them with an insecticide. When growth is completed stand the plants out of-doors in a sheltered situation and allow them to remain in the open until there is danger of frost in the autumn.

COLEUS THYRSOIDEUS.—If cuttings of Coleus thyrsoidens are available insert them without delay, as a long season of growth is required to make good plants. Prepare a finely-sifted compost of loam, peat, leaf mould, and sharp sand. The cuttings are best rooted in small pots, and it is important that the receptacles be plunged in a hot-bed until roots develop. When the cuttings are rooted place them on a shelf near the roof-glass in a house having a moist, warm atmosphere. When they are sufficiently well rooted pot them singly in 3½-inch pots, and stop the leading shoots when they are about 6 inches high to induce others to break from the base. About three or four shoots should be retained to form a good specimen. At a later stage shift the plants into 5-inch pots, using the same kind of compost as before, but passed through a coarse sieve. For the final potting use 7-inch or 8-inch pots. Another batch of cuttings rooted in a few weeks' time will furnish plants for flowering in small pots. Seedlings of this Coleus raised from seed sown early in March require similar treatment.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

PERPETUAL-FLOWERING CARNATIONS.—Old plants of Perpetual flowering Carnations may be planted in borders or beds at any time now, and the sooner the better. The soil can scarcely be made too firm about the roots, and a very shallow basin should be left round each plant for the reception of water. It is a good plan to water the plants at regular intervals, always on the same days of the week, until root action has commenced, for if the balls once become dry it is almost impossible to moisten them again unless hot water is used, and drought at the roots will be followed by a yellowing of foliage, which renders the plants unsightly. Unless the stakes are very strong and intact when the plants are set out, one new, strong stake should be placed to each Carnation and the stems securely fastened to it. This support will usually suffice for the season.

STOCKS.—If the ground is ready for the reception of East Lothian Stocks they should be planted forthwith, the soil having been previously enriched with a dressing of decayed cow manure. Those prepared in boxes require careful handling to preserve a ball of soil with the roots, which is necessary to the satisfactory establishment of the plants. Stocks repay frequent watering until root-action has become vigorous.

GLADIOLUS.—This is the period when most Gladioli are planted (at any rate in the North) from the pots or boxes in which they have been forwarded under glass. The newer hybrid bedding varieties do not require this treatment, and they succeed well if planted much earlier in the year.

BEDDING PLANTS.—Houses may now be cleared of the more tender bedding plants, and these may be transferred to cold frames, where they should remain until danger of cold winds is past. Lobelias growing freely will require the tips of the little shoots taken off, and Ageratums should be pinched to keep them stocky. Should there be indications of exhaustion of soil, slight manurial additions should be made to the water when moisture is required.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—*Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

The Chemical Life History of the Potato.

Messrs. J. T. Ramsay and W. C. Robertson, of the Department of Agriculture, Victoria, Australia, have published* the results of an inquiry into the composition of the Potato plant at various stages of its development. Their object was to ascertain the rate at which the plant absorbs food from the soil and the relative proportions of each of the principal "elements" (nitrogen, phosphoric acid, and potash) contained in the plant at various stages of growth. The results are interesting, and of practical value.

In order to obtain them, the authors made complete analyses of set, haulm, root and tuber at four stages of the life-history of the Potato, and at intervals of 33, 25, 31 and 35 days—that is, roughly, at the end of the 1st, 2nd, 3rd, and 4th (last) month of growth.

The first point of interest which appears from these analyses is that 41 per cent. of the total *root growth* is completed during the first month. In the second month the plant performs 52 per cent. of its root-growth, and at the end of that period root-growth is practically complete.

During these two periods the haulm makes 22.5 per cent. of its total growth in the first month and 49.8 per cent. during the second. In the third month the root ceases almost entirely to grow, but the haulm makes 27.7 per cent., practically finishing its growth within three months.

The authors rightly point out that this active and precocious root-development indicates that soluble food substances must, if they are to contribute to the essential and considerable root-growth which takes place in the first month, be available from the start. Herein lies the justification of supplying sulphate of ammonia and super phosphate of lime before or at the time of sowing, and it would appear to follow that the practice of withholding the sulphate of ammonia until the time of the first earthing up is not to be recommended.

Analysis of the sets shows that much of the nitrogen and phosphoric acid which they contain is drained away from them to the growing plant, and assists in building up root and haulm, but the potash contained in the set remains there, and does not apparently pass into the growing plant, but finds its way ultimately into the soil. The potash absorbed by the roots accumulates for a time in the haulm, but later on passes to the tuber, where it, as is well known, plays an important but obscure part in facilitating the accumulation of starch in the tuber.

The second month of growth sees a great accumulation of nitrogen, phosphoric acid, and potash in the haulm. The nitrogen increases from 62.9 lbs. (per acre of haulm) at the end of the first month, to 164.2 at the end of the second; the phosphoric acid increases from 13.3 to 39 lbs., and the potash from 91.7 to 261.7. During the following month—the third—these materials begin to migrate to the young tubers, and as a result there is a falling off in nitrogen in the haulm (from 164.2 lbs. per acre of haulm to 143.3), and a falling off in phosphoric acid (from 39 to 20.9). The potash in the haulm shows a slight increase—from 261.7 lbs. per acre of haulm to 265.7, but the lime in the haulm, on the other hand, shows a steady and continuous rise—22.1 lbs. in the first month, 68 lbs. in the second, 126.5 in the third, and 131.4 at the end of the fourth month.

No less interesting is the amount of food removed by the plant and the amount returned by the haulm. A 10-ton crop of tubers contains about 2 tons of dry matter, and the haulm of such a crop 1 ton of dry matter. The amount of food contained in the haulm per acre is 45 lbs. of nitrogen, 7 lbs. of phosphoric acid, 84 lbs. of potash, and 51 lbs. of lime (and 25 lbs. of magnesia), plus a little less than a ton of organic matter.

The tubers of the crop receive from an acre of land 81 lbs. of nitrogen, 31 lbs. of phosphoric acid, and 144 lbs. of potash; that is, the equivalent of a dressing of 4 cwt. of sulphate of ammonia, 1¼ cwt. of superphosphate, and 3 cwt. of sulphate of potash.

The authors conclude by drawing attention to the high manurial value of the Potato haulm. One ton of haulm supplies three times as much nitrogen and phosphoric acid, and approximately ten times as much potash, as 1 ton of farmyard manure. The large demand of the Potato for potash is illustrated by the fact that during the growing period it utilises phosphoric acid, nitrogen, and potash in the ratio of 1, 4 and 6.

* *Journ. of the Dept. of Agric.*, Victoria, XV., ii.

THE ROYAL PARKS.—On the vote of £57,000 for expenses in connection with the public Royal parks and pleasure grounds of London on the 18th inst., complaints were made in Parliament of the way in which the parks had been disfigured by the erection therein of temporary buildings. Sir J. BOYTON declared that the whole inner circle of Regent's Park was a stable for motor-lorries, and the amenities of the park had been entirely destroyed. Sir ALFRED MOND, the First Commissioner of Works, said he sympathised very heartily with what had been said with regard to the condition of the parks. He was not responsible for the buildings which had been put up in Regent's Park, but he would limit the erection of further buildings in the parks so far as he could. It was certainly undesirable that any further part of St. James's Park should be utilised for buildings.

MEMORIAL TO MISS ETHEL SARGANT.—The Council of Girton College has decided to endeavour to raise a sum of money with which to found a scholarship for the encouragement of research in botany, as a memorial of Miss ETHEL SARGANT, whose original contributions to botany gained for her a prominent and honourable position in the scientific world. Miss SARGANT was not only an original investigator of great ability, but she also consistently advocated the importance of providing opportunities of research for others. She was the first woman to preside over a section of the British Association and to serve on the Council of the Linnean Society. Subscriptions may be sent to Miss E. LAWDER, 25, Halifax Road, Cambridge.

CELERY LEAF BLIGHT.—Celery leaf blight disease is often carried in the "seed," and growers are advised to disinfect their seed with a solution of hydrogen peroxide known commercially as 20-volume solution, but if that cannot be obtained a 10-volume solution may be used. The seed to be treated should be placed in a glass or earthern vessel and enough of the hydrogen peroxide poured into it to cover the seed completely. Allow the seeds to remain in the liquid for three hours, and then pour the liquid off and use it a second time if required. Spread the seed in a thin layer in the air before sowing. Do not return the seed so treated to the original packets, as spores of the fungus causing the disease may be adhering to the paper of the packets and thus re-infect the seeds. If the plants become infected at a later stage spray with Bordeaux or Burgundy mixture.

THE GRAPERIES OF BAILLEUL.—An incident of the fierce fighting around Bailleul, described in Mr. PERCIVAL PHILLIPS' despatch in the *Daily Express*, was the destruction of the famous graperies which supplied the London market for a number of years. The black Grapes of the Bailleul district were at one time almost the only Grapes we received from France. But we have not had any of these Bailleul Grapes in London for a long time. For several years before the war they all went to the Paris market. Another battlefield, Waterloo, used to send its famous black Grapes to London. Paris was formerly the market for these Belgian Grapes, but in consequence of a tariff imposed by the French they were sent to Covent Garden.

REGISTRATION OF DAFFODIL NAMES.—At the meeting of the Royal Horticultural Society on Tuesday, April 9, the President and Council adopted a recommendation of the Society's Narcissus Committee that Regulation 3 for the registration of Daffodil names be suspended *sine die* as from August 1, 1914. Regulation 3 reads as follows: "If flowers of plants registered be not exhibited for confirmation of name at one of the R.H.S. meetings within a period of five years from the date of registration, the registration will lapse, and the name having been erased from the Society's list will again become free for adoption."

A VETERAN AHUACATE TREE.

THE Ahuacate (Persea gratissima), known in English-speaking countries under a number of different names, but most commonly as Avocado and Avocado Pear, has, since the remotest antiquity, been a great favourite with the Mexicans. Some of the earliest historians record having found the tree in the dooryards of the Aztecs, and the fruit was a staple food product with them. The town of Ahuacatlan takes its name from this fruit, *tlan* being the Aztec place termination. To-day the Ahuacate is no less highly valued by the natives than it was in the time of Columbus, and in many districts it is to be found in immense numbers.

The tree shown in the illustration is growing near the village of Atlixco, in the State of Puebla directly at the foot of the great volcano Popocatepetl, and at an altitude of over 6,000 feet where freezing temperatures occur almost every winter. The owner of this tree, when questioned as to its age, merely replied that it was "muy anciano." "Is it one hundred years old?" "Yes. Some much more than that." "Two hundred years?" "Yes. Some fully that much." The trunk is over 4 feet in diameter, and despite its old age the tree is still vigorous and produces annually about three thousand fruits. An idea of the sizes of these fruits can be gained from those shown in the hand of the owner; they weigh almost one pound each. The fruit is in great demand among the natives, and in order to prevent its being stolen it is picked a month or six weeks before fully mature, and placed in the house to ripen. In this way it softens sufficiently to be eatable, but is far from being as good as when allowed to attain full maturity on the tree. The natives gather the fruits in a very crude manner, prying them off the tree with a long pole provided with a hooked wire on one end, and allowing them to drop to the ground. When picking from the uppermost branches, some fifty feet above the ground, it is not hard to see that it requires a fruit of extraordinary strength of skin and solidity of flesh to stand the terrific jolt to which it is subjected. Some of the Mexican and Central American Ahuacates are remarkable in this respect having a skin so thick and woody that it could almost be called a shell. *E. W. D'yer.*

FIG. 79.—PERSEA GRATISSIMA IN SOUTHERN MEXICO.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

ANEMONE PULSATILLA.—In confirmation of the remarks of Mr. W. P. Dykes on p. 165, I should like to say that here I have found Anemone Pulsatilla very variable in colour. Some flowers are very dark purple, others more mauve. Seedlings raised from the former colour invariably produce a large percentage of the latter. They thrive and do well here on W. shire even on a herbaceous border, although, of course, they seem much more at home on the rockery. *R. H.*

SCARCITY OF PEAR BLOOM (see p. 170).—It seems difficult to provide any theory which will explain the condition of Pear trees this year. The trees generally are remarkable for the absence of bloom, and this fact, taken in connection with the abundant crops of last year, tempts one to agree with the old theory that a heavy cropping season is almost necessarily followed by a more or less fruitless one. The evidence, however, is conflicting. In some districts trees which cropped heavily last year, and those which bore few or no fruits, are now alike deficient in blossom. In others there is abundant promise of a full crop. Thus we find divergencies even in trees which bore heavily last year. In my own garden, for instance, there are two large trees, growing side by side, which bore heavy crops last year. One, a Williams' Bon Chrétien, is white with bloom, while the other, a late variety, not identified, has only two trusses. It may be suggested that Williams' Bon Chrétien, having been relieved of its fruits sooner than the late tree, had sufficient time to recover from the strain of fruit production and flower again. But the instance quoted is far from being an isolated one. In gardens around Taplow, Maidenhead, and alongside the G. W. Railway main line at Hanwell, Southall, and West Drayton, many large Pear trees which bore heavy crops last year are now smothered in blossom. The profusion of bloom on nearly every Plum tree in Isleworth and Hounslow, which bore such heavy crops last year that many branches were broken down by the weight of fruit, decidedly refutes the theory that a fruitful season is followed by a year of scarcity. *A. C. Bartlett, The Orchard, Uxbridge Road, Hampton.*

My experience agrees with that of Mr. Beckett in a somewhat modified degree. Every year at this season a large winter Pear in my garden is one mass of white blossom, but the crop varies considerably. In 1914, and again last year, it was very large, but in the intervening and the two years previous to 1914 the yield was very small. Within a few yards of my Pear tree there is in the adjoining garden an early Pear, less than half the height of mine, which never fails to produce a good crop, and this year was as usual one sheet of white blossom just before the cold spell of the last week or two. My tree usually comes into flower later than my neighbour's, so I am hoping it may yet flower under the influence of warm sun, but a crop of fruit like that of last autumn is past hope. *W. Roberts, 18, King's Avenue, Clapham Park, S.W.*

—I do not think Mr. Beckett will be alone in his experience this year. I have never had less bloom on my Pears since I replanted my wall twelve years ago. This scarcity is especially noticeable on trees growing on walls. I partly account for this by the heavy crop taken last year, but this is not so in all cases. Trees that only gave me a few fruits last year are equally bare of bloom; yet the bush trees growing by the path in the garden are mostly showing plenty of bloom, as also are cordons planted fifteen months ago. Apples, on the other hand, give every promise of an abundant crop. This I am surprised to find, after the heavy crops taken last year. Even varieties that bear more or less every other year are showing well for bloom. Plums, Apricots, Peaches, and all bush fruits are most promising. *T. Pateman, Node Gardens, Welwyn, Herts.*

Here in these gardens, and in the locality generally as far as I can see, scarcity of Pear bloom is general. Williams' Bon Chrétien and Pitmaston Duchess, however, are exceptions to the rule, as they are bearing quite a wealth of bloom; but others, e.g., Doyenné du Comice, Louise Bonne of Jersey, and several of the Beurrés have scarcely any blossoms. One hardly

knows to what extent even the little bloom they now have may be damaged, seeing that on the 18th and 19th of April we had 19 and 9 degrees of frost respectively, on the latter date after a fall of snow. On subsequent examination I found all blooms frozen stiff, and many were ruined. Plums and Damsons are splendid everywhere, but possibly we shall hear of great damage in the next issue of the *Chronicle*. Here we had a quantity of snow on the 16th, enough to give the country around quite an Arctic appearance. *R. H. Legg, Melksham House Gardens, Wilts.*

WEATHER RECORDS.—Will those interested in the relation between garden or field culture and weather variations, assist in the work carried out over some forty years by the Royal Meteorological Society, and, since 1890, on a uniform plan initiated by the late Edward Mawley in the annual reports on phenological observations? Their value grows with the years, but from the first the cry has risen for more observers, particularly throughout Wales, Scotland, and Ireland. The accompanying map exhibits this paucity; also, however, the fascinating floral march across the land by the isophenes, or lines of equal flowering date, counting January 1 as 1. Hence 120 stands for April 30. In the parts named especially, but also all over, we are anxious to enrol fresh observers for the 13 common wild flower, 6 bird, and 5 insect records. I shall be most pleased to send the necessary forms and instructions. Among earlier observations are the first appearance of Coltsfoot, Anemone, Blackthorn, swallow, honey bee (visiting flowers). Any migrant records are valued. *J. Edmund Clark, Asgarth, Riddlesdown Road, Purley, Surrey.*

EARLY-FLOWERING SHRUBS (see pp. 112, 130, 141, 150).—Both Prunus Pissartii and Forsythias have flowered in South-west Scotland with more than usual freedom this spring. P. Pissartii has been charming, and Forsythia intermedia, F. Fortunei, and F. densiflora have been unusually floriferous. *S. Arnott, Maxwelltown, Dumfriesshire.*

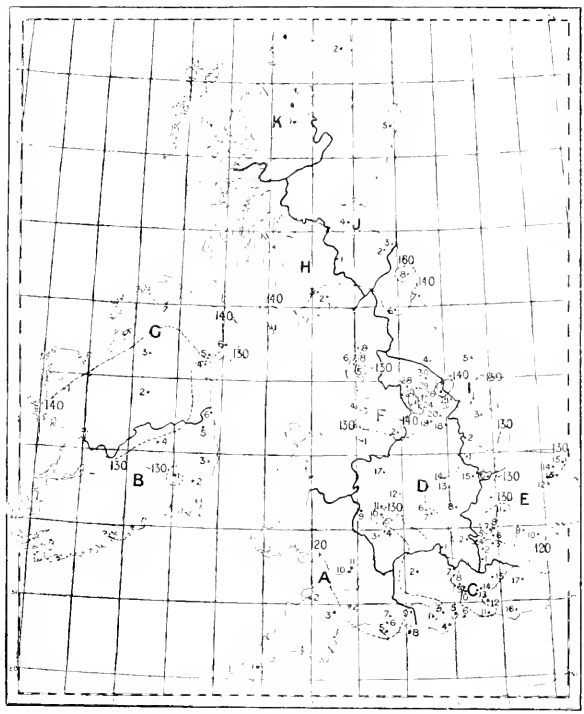

FIG. 80.—PHENOLOGICAL STATIONS, 1916. ALSO ISOPHENES OF 120, 130, 140 AND 160 DAYS FOR 1916.

SOCIETIES.

ROYAL HORTICULTURAL.

APRIL 23.—The weather on Tuesday last was about as wet as could be imagined; at Westminster there was an all-pervasive darkness and dampness, at once depressing to the spirits, and so gloomy as to prevent anyone from properly appreciating the delightful colouring of the new Orchids and Daffodils on exhibition at the Drill Hall. Both these classes of flowers were well represented, and there was also a fine collection of Himalayan and other Rhododendrons, various Alpine and other early spring flowers, and Auriculas and Primulas.

The Fruit and Vegetable Committee had very little work to do. The Floral Committee recommended one Award of Merit and awarded a few medals. The Orchid Committee considered several novelties. The Narcissus and Tulip Committee recommended three Awards of Merit and five medals. This Committee awarded the Engleheart Cup to Messrs. HERBERT CHAPMAN, LTD., for the best dozen Daffodils not in commerce; there were four entries. The Peter Barr Memorial Cup was awarded to Miss WILLMOTT, V.M.H., Warley Place, Great Warley, for the year ensuing, as an acknowledgment of the good work this lady has done in popularising Daffodils.

Floral Committee.

Present: Messrs. Henry B. May (in the chair), Sydney Morris, John Green, R. W. Wallace, John Heal, J. F. McLeod, Geo. Harrow, C. R. Fielder, E. F. Hazelton, G. Renthe, W. Howe, H. Cowley, Thos. Stevenson, W. H. Page, Arthur Turner, Chas. Dixon, John Dickson, Chas. E. Pearson, W. P. Thomson, E. H. Jenkins, Geo. Paul, J. W. Barr, W. B. Cranfield, H. J. Jones, and W. G. Baker.

AWARD OF MERIT.

Daphne rupestris grandiflora.—A dainty little shrub of lowly Alpine growth, with short, closely set leaves and sweetly scented deep rose-pink flower of larger size than found in the usual form. From Messrs. R. TUCKER AND SONS, Oxford.

GROUPS.

Messrs. R. GILL AND SONS showed delightful Rhododendrons, especially the rich-hued Norman Gill, Gill's Crimson, the clusters of R. Nuttallii, R. campyloglossum, and the fine R. Falconeri. (Silver Flora Medal.)

Messrs. R. TUCKER AND SONS showed a large-flowered form of Daphne rupestris, the fragrant Viburnum Carlesii and Androsace pyrenaica.

Messrs. FELTON AND SONS showed some vases of charming Roses and of Double Gerbera. (Bronze Banksian Medal.)

Messrs. B. R. CANT AND SONS contributed Roses in fine form, their A. Hartmann, Emily Gray and Golden Ophelia being prominent. (Silver Flora Medal.)

Mr. GEORGE PRINCE also exhibited Roses, his group including Yellow Banksian bending over larger flowered varieties in low vases. (Silver Banksian Medal.)

Messrs. H. B. MAY AND SONS showed Ferns. (Silver Banksian Medal.)

Mr. G. REUTHE and Mr. G. W. MILLER showed hardy flowers. (Bronze Banksian Medals.)

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), R. A. Rolfe, R. G. Thwaites, Fred. K. Sander, T. Armstrong, A. McLean, J. Charlesworth, J. E. Shill, W. H. White, Walter Cobb, Frederick J. Hanbury, C. J. Lucas, R. Brooman White, and W. J. Kaye.

AWARDS.

FIRST CLASS CERTIFICATE.

Brasso Cattleya Princess Mary (*B.-C. Digbyano-Schroderae* × *C. chocoensis alba*), from Messrs. FLORY AND BLACK, Slough. A very handsome and distinct hybrid, partaking much of the fine form of C. Schroderae, but broader in all its parts and of fine substance. The broad sepals and petals are white with a slight blush tint on the reverse side, the fine circular-fronted fringed lip white, with rich orange disc and throat to the tube.

AWARD OF MERIT.

Odontioda Joan var. Rochampton (*Oda. Charlesworthii* × *Odm. ardentissimum*), from Dr. MIGUEL LACROZE, Brymdr, Roehampton (Orchid grower Miss Robertson). An ideal flower, of large size, perfect shape, and remarkably intense dark colour. The broad sepals and petals were entirely rich claret colour, with a dark maroon shade and a very slight white margin.

PRELIMINARY COMMENDATIONS.

Odontoglossum Miguelito (*Dora* × *Doris magnificum*), from Dr. MIGUEL LACROZE. A charming seedling, bearing one large claret-coloured flower of fine shape and substance, the outer parts of the segments being white and other slight white markings appearing between the large blotches.

Odontoglossum General Foch (*Armstrongiae* × *Colossus*), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells. A good result in fixing blue and violet colours, for which Messrs. Armstrong and Brown have made successful endeavours. The flower borne by the seedling plant was 3½ inches across, the ground colour white, with the greater part of the surface of the sepals violet, the fringed petals bearing numerous irregular violet blotches. Lip ample, white, with violet blotches in front of the crest, which constitutes a distinct feature, as the blotching of the lip is usually brown or red, and not coloured like the petals as in this seedling.

GROUPS.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), was awarded a Silver Flora Medal for an effective group, in which were a good selection of Miltonias, including a fine specimen of M. vexillaria Memoria G. D. Owen, with four spikes bearing together 17 flowers. Among the Odontoglossums were the fine O. Hallii King Edward VII., O. crispum Snow Queen, O. c. Oakwood Ruby, and other rare forms.

Dr. MIGUEL LACROZE, Roehampton, showed two good novelties in Brasso-Cattleya Beaumont

B. C. Chittoni magnificum, C. Empress Frederick, a good blush-white flower with greenish-yellow disc to the lips; and Odontioglossum Catanaroa Sceptrum, Fascinator, primrose-yellow with dark spotting.

Messrs. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for a very fine group containing a selection of new hybrid Odontioglossums, among which Odm. Bullecourt, O. eximium Xanthotes and other white forms were conspicuous. Among the showy Odontiodas, Oda. Henryi, with a rich spike of cinnabar red flowers, was the most attractive.

Messrs. CHARLESWORTH AND CO. were awarded a Silver Flora Medal for a group of fine Odontoglossums, Odontiodas, Laelio-Cattleyas, etc., with well-flowered white Dendrobium Infundibulum and D. Lamellianum.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a silver Banksian Medal for an attractive group, principally hybrids, the new forms being L.-C. Marcia, L.-C. Mrs. J. Schroder, a pretty pure cowslip-yellow flower, and L.-C. Semia, L.-C. Fetonia, C. Schroderiana, formed like C. Schroderæ, blush white, with orange disc. Fine specimens of L.-C. eximia, with fine flowers, L.-C. Dominiana, and the white Brassocattleya Queen Alexandra with four flowers, were also shown.

Messrs. C. F. WATERS, Balcombe, were awarded a Bronze Banksian Medal for a selection of well-flowered exhibit Dendrobiums, including a good white form of D. Ainsworthii, and the richly-coloured D. splendidissimum var. Mrs. Haywood.

Mr. J. E. SHILL, The Dell Gardens, Englefield Green, showed a splendid plant of Odontioda Duchess, with a branched spike of many well-formed flowers, handsomely blotched with bright red on a blush-white ground.

Messrs. FLORY AND BLACK, Slough, showed their new seedling Cattleya Peter Hardyana × Venus, nearest to C. Hardyana, and with yellow sepals and petals tinged with rose, the rose-mauve lip having the gold lines of C. Dowiana aurea and the yellow patches on each side of the lip as in C. Warscewiczii, one of the parents of C. Hardyana.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Miss E. W. Ingott, Rev. J. Jacob, Messrs. P. R. Barr, W. Poupart, F. H. Chapman, Horace Smith, W. B. Crisfield, Francis Boyd, Richard R. Wallace, W. F. M. Copeland, G. Reuthe, G. W. Leak, E. D. Pearson, and Chas. H. Curtis (hon. sec.).

AWARDS OF MERIT.

Narcissus Glowing Bowl.—A beautiful and greatly admired Daffodil with a white perianth of excellent form. The crown of yellow hue has a deep, frilled rim of vivid mandarin red. This belongs to the Barrii class, though a three-quarter bred poeticus. From Messrs. HERBERT CHAPMAN, LTD., Rye, Sussex.

Narcissus Miss E. M. Boarding.—A very dainty Giant Leedsii variety with faultless white perianth segments and a frilled Apricot-tinted pink-flushed trumpet. This is not a large flower, but so beautiful and well balanced as to attract considerable attention. From Mr. W. B. CRANSFIELD, Enfield Chase, Middlesex.

Narcissus Spalding Queenie (*N. poeticus ornatus plenus*).—A beautiful double white form of the popular N. ornatus, and particularly useful for market purposes and florists' use. It gained an Award of Merit as a show flower in May, 1917, and on the present occasion was granted a similar award as a market variety. From Messrs. F. CHIPPIN AND SON, Narcissus Gardens, Spalding.

GROUPS.

Mr. A. ROBINSON, Doncaster, is a new exhibitor at Westminster; he showed a great variety of Daffodils, amongst which were Orangeman, Mrs. J. H. Veitch, Cœur de Lion, Firebrand, and Croesus.

Messrs. HERBERT CHAPMAN, LTD., displayed a fine lot of poeticus forms and such brilliant varieties as Torso, Crimson Braid, Whitewell, and Débutante. (Silver-gilt Banksian Medal.) In their exhibit, which won for them the Engleheart Cup, this firm showed Bardmaster and Nell Gwynne in capital condition.

Major CHURCHER, Alverstoke, showed Will Scarlet, Red Beacon, and Gipsy Queen in good form.

Mr. W. F. M. COPELAND'S group included the handsome double Mary Copeland and the still more double Mrs. Maurice Malcolm, with many dainty seedlings representing other sections.

Messrs. BARR AND SONS had the best Daffodil display, and gained a Silver-gilt Flora Medal for their clean, bright flowers; Dolores, Red Beacon, Pyrrha, Ruby (finely formed), Cossack, Elvira, and Radiant were a few of the finer flowers in this group.

Fruit and Vegetable Committee.

Present: Messrs. Joseph Cheal (in the chair), H. Markham, P. D. Tuckett, J. C. Allgrove, Edwin Beckett, F. Jordan, E. Harriss, E. A. Bunyard, F. G. Tressider, W. H. Divers, A. Bullock, Geo. P. Berry, A. R. Allan and W. Wilks.

A few seedling and other Apples were placed before this Committee, but there were no other exhibits, and no awards were made.

NATIONAL AURICULA AND PRIMULA.

APRIL 23.—War conditions and weather conditions combined to make this society's exhibition, held in connection with the Royal Horticultural Society's meeting, a somewhat poor one. In many classes there were no entries and in others only one. Some of the flowers shown were quite good, but there was an entire absence of enthusiasm, and very few Auricula lovers were present.

Mr. J. T. BENNETT POE was the only exhibitor of two stage Auriculas. Mr. J. L. Gibson showed the finely-edged Auricula a good plant of Marmion, which gained a 1st Prize. For four show Auriculas Mr. Gibson gained first place, and showed, among others, a fine violet self-coloured variety.

Mr. BENNETT POE was first and second for six Alpine Auriculas, and showed Hero of Hyde in each case. Mr. J. L. Gibson had in the class Lucy, Alpine Auricula raised by Bennett Poe, Stephen Berry, Dwight, Guide Helper, Mrs. Jas. Douglas, and Prime Minister. Mr. H. W. Mason was placed second. Mr. Gibson was also awarded 1st Prize for six fancy Auriculas, showing Good Work, Kate Nicholson and some good seedlings.

The 1st Prize in a second class for six Alpine Auriculas was won by Mr. J. T. BENNETT POE with Golden Dustman, Duke of York, Argus, Dean Hole, Rosy Morn and J. T. Bennett Poe. For four Alpine Auriculas Mr. J. L. Gibson, Belmont, Surrey, won the first place for a good set, and was followed in order by Mr. J. T. BENNETT POE and Mr. H. W. MASON, Barstead.

Mr. G. W. MILLER, Wisbech, secured the 1st Prize for a collection of Primulas and Auriculas, and had no competitors. The best dozen Polyanthuses also came from Mr. G. W. Miller, who won the 1st Prize for a specimen Polyanthus, for a dozen Primroses and for six Primroses, the colours of the flowers in those classes being bright and varied.

CROPS AND STOCK ON THE HOME FARM.

VETCHES FOR HORSES AND COWS.

VETCHES are very useful for providing green food of an appetising nature for horses in August and September when they are doing extra work during harvest. Cows, too, appreciate them, and so do pigs, especially when they are podded. Two bushels of seed per acre, with half a bushel of Oats, should be sown broadcast on deeply ploughed land that may have produced a crop of roots during the winter. Manure freshly applied is not absolutely necessary. Harrow the ground well after sowing, and see that birds do not rob the seed.

Winter Vetches intended for sheep food, hay or seed, should be rolled without delay, especially in light soil, as recent frosts have loosened the surface. If it is not soon made firm again by the roller red rust may affect the growth.

MAIZE.

Cowkeepers who have not hitherto grown Maize as green food for their cows are realising its advantages in increasing the milk supply during August, September and October.

The second or third week in May is quite soon enough to sow the seed. If sown earlier in stiff soil, which is liable to be cold and wet, the seed rots; or the growth may be injured by late frost. Plough the land deeply, working it down to a fine filth, so that when ploughed again for sowing the fine surface soil will fall on the seed. This should be sown thinly in the furrow behind the plough, the furrow being, say, 3 inches deep. This is better than drilling the seed, as with the latter method some of it is sure not to be buried more than an inch deep. Rooks quickly find such stray seeds, and harrow for more, often spoiling the whole plot.

If the land was not previously manured, scatter in the furrow some superphosphate. The seed need not be sown closer than 3 inches apart.

TRIFOLIUM INCARNATUM.

sown last August or early in September to provide cattle food in May and June, is progressing favourably on well-enriched land. Liberal cultural conditions in regard to manure and thorough preparation are a great advantage. Plots that are not making satisfactory growth should be aided by a dressing of sulphate of ammonia sown over during dry weather at the rate of 1 cwt. per acre.

MANGOLD.

Now is the time to make final preparation for the sowing of Mangolds. The value of this root is well known. It may form the staple food for dairy cows from November until the middle of May. For sheep Mangolds can be used during the lambing period in February, and from then onwards until August. For horses they can be used daily from January until May, or later; and for pigs all the year round.

The best preparation for this crop is farmyard manure, ploughed in in November at the rate of 20 tons per acre, followed by 3 cwt. superphosphate in the spring, previous to sowing. The various manure merchants prepare a concentrated form of manure for this crop which saves the labour and expense of carting farmyard manure. Agricultural salt is beneficial, especially on light soil, as it conserves the moisture in the soil; 1 cwt. salt sown over the plot ten days before sowing the seed, and 5 cwt. superphosphate per acre will be sufficient, provided the soil has been well manipulated and is fairly free from weeds. Sulphate of ammonia sown evenly over the land at the rate of 1 cwt. per acre after thinning the plants is of great assistance to this crop. No time should be lost in getting in the manures to be applied, as delay in delivery may occur.

Manure can be applied with the seed in the drill, but it is better to sow broadcast, whatever the kind. Manure sown in the drill with the seed is liable to check the early growth; by distributing it over the plot it is made more available for future growth. If the weather is dry, and the land in good working condition, sow the seed in April. Early sowing provides a longer season of growth, and enables the roots to be lifted earlier in the autumn. The earlier storing of the roots renders them more secure from frost. Early sowing, too, enables the plants to be set out, thinned, and hoed before haymaking begins, which supersedes such work as hoeing. 2 lbs. of seed per acre is sufficient to produce a full plant. As to variety, this is a matter for circumstances. For cows in milk grow Golden Tankard. For sheep grow the Globe type, as it yields more bulk.

Mangold in clamps intended for food for some months yet, should be exposed to the air, and would be all the better if turned over, to check both root and top growth. Such growth is now taking place, owing to lack of air and light. Should there be any decayed roots they should be removed as having a tendency to contaminate those in contact with them. The sprouts should also be removed, as if fed to cattle or sheep they are apt to cause scour. In the case of cows, where the roots are put through the slicer or pulper the top (crown) of the root as well as roots and all dirt should first be removed, giving the animals only the clean root. Such details are of the utmost importance in obtaining satisfactory results. *E. Molyneux*.

REMARKS.—Supplies are considerably less this week owing to weather conditions. Arums (Richardias) are back to the prices realised at Easter, and Lilium longiflorum is very dearly. L. lancifolium is unobtainable. All white flowers are exceptionally scarce, and prices considerably higher. Small white flowers required for making designs will be difficult to obtain during the next two or three weeks. Small quantities of Stephanotis and Lapagerias are now being received, and Gardenias are increasing in number. Lily-of-the-Valley is very limited. Roses were considerably checked by the cold weather and lack of sunshine. Red and white blooms were in great demand for St. George's Day, red blooms realising from 5s. to 12s. per doz., and white from 4s. to 8s. Mme. A. Chatenay, Melody, Lady Ley, Sunburst, White Molly Sharman Crawford, Liberty, and Richmond are arriving in excellent condition, though they are not very plentiful. Spanish Iris is arriving in fine condition.

Watercress, per doz	0 8- 0 10	

REMARKS. Stocks of English Apples are now practically cleared, but French Russets are still available. The old crops of English Grapes are finished, and the new season's Black Hamburgh are on offer, as are also Green Figs and Peaches. Morning-gathered forced Strawberries are available in fair quantities for the season of the year. Lemons and Oranges continue to be scarce and expensive. Cases of Dates are now on offer containing about 2 lbs. weight of fruit. Supplies of Tomatos (English and Channel Islands) are increasing daily. Dwarf Beans have been a shorter supply this season than usual, and supplies of forced Seakale are limited. Outdoor Seakale is fairly plentiful. Asparagus, English and Continental, is limited in quantity, but supplies of Cucumbers and Vegetable Marrows are increasing. Mushrooms are not so plentiful, and English Onions are unobtainable. Valencia and French Onions are fairly plentiful, but are not keeping well. Outdoor vegetables and roots have advanced in price. *F. H. F. Covent Garden Market, April 25, 1918.*

Obituary.

J. HARRISON DICK.—Mr. J. Harrison Dick, whose early death we announced in our issue of April 6, p. 151, was born in Edinburgh on October 13, 1877, in the district of Morningside. When about four years of age, the family went for a time to Aberdeen. His father being appointed head gardener to Lieut.-General Henry,

THE LATE J. HARRISON DICK.

C.B., at the Pavilion, Montrose, the family returned to the Edinburgh district, and on this famous estate he spent his early days. In November, 1893, he went to Morton Hall, Liberton, as outside journeyman. Up at six every morning, he studied until eleven or twelve at night, and walked three miles to Edinburgh twice a week, all winter, to attend lectures. His next place was Trinity Grove, Edinburgh, close to the Botanic Gardens, at which latter place he obtained permission to attend the classes on botany, physics, chemistry, and landscape gardening. In 1898 he went to Veitch's Nursery, Chelsea, and a little later to Nostell Priory, Wakefield. In April, 1899, he joined the *Gardening World*, of London, as a reporter. He was appointed sub-editor of the *Journal of Horticulture* in February, 1901, and took over the editorial chair in November, 1911. During his five years at Edinburgh, Mr. Dick gained certificates and prizes for proficiency in such subjects useful to a gardener as botany, organic chemistry, entomology, surveying, and mensuration. He studied wash drawing at the Birkbeck College, and some of his illustrations have appeared in the *Journal of Horticulture*. Mr. Dick was a member of the committees of the National Sweet Pea Society and National Dahlia Society, and vice-chairman of the executive committee of the United Horticultural Benefit and Provident Association. He became editor of *The Florists' Exchange*, of America, in October, 1913.

Mr. Dick was responsible for the inception and editing of the *Gardeners' and Florists' Annual*, in the preparation of the several issues of which he devoted much of his spare time. For the A. T. De La Mare Co. he wrote *Sweet Peas for Profit*, *Commercial Carnation Culture*, and *Mushroom Culture*, these books enjoying an active sale among the trade. He edited the first issue, in 1917, of *Garden Guide, the Amateurs' Handbook of Gardening*, a most successful book. He made an efficient secretary of the American Dahlia Society, and compiled all its recent bulletins. He was re-elected on the executive committee of the American Sweet Pea Society at its annual meeting last July, and compiled its first bulletin. His position as editor of the *Florists' Exchange* provided him with the opportunity to visit all the large centres of the East and Middle West of the United States. Wherever he went he made warm friends, for with all his knowledge he was modest and unassuming, lovable and approachable by all. He leaves a widow and one young daughter.

ENQUIRY.

A READER will be much obliged if someone will supply her with a recipe for cooking Soy Beans. *M. F.*

DEBATING SOCIETIES.

BUSHEY AND DISTRICT GARDEN AND ALLOTMENT ASSOCIATION.—At the fortnightly meeting of the above society on the 9th instant, Mr. T. W. Birkinshaw, Gardener at Caldecote Towers, Bushey Heath, gave a lecture to the members on "Salad Plants and their Cultivation." He mentioned about a dozen varieties which were most serviceable for salads, and gave the full treatment of each variety. After the lecture a general discussion took place, and many questions were asked.

CATALOGUE RECEIVED.

ALLWOOD BROS., Wivelsfield Nurseries, Haywards Heath, Catalogue.

ANSWERS TO CORRESPONDENTS.

FLUE DUST: *J. H.* In appearance the sample of dust you submit resembles some of the flue dusts rich in potash, but no definite opinion can be given without a chemical analysis. Probably a local analyst would examine it for you for a small fee.

NAME OF FRUIT: *B. E.* Brabant Bellefleur.

NAME OF PLANT: *F. C., Guildford.* Staphylea pinnata, a Southern European shrub, also found growing wild in some parts of Great Britain.

RADIUM: *F. J. I.* An article on the subject of radium and plant-growth appeared in our issue for September 16, 1916, which can be obtained from our publishing department, price 3½d. post free. If you want a fuller work, Messrs. Sutton and Sons, Reading, have published an account of a series of experiments which you can obtain from them at 2s. 6d. net per volume, plus postage.

TOMATOS: *W. H. C.* The seedlings were heavily infested with disease; some were affected with bacteria, other stems were filled with the mycelium of a fungus. No measures short of the removal and destruction of such diseased seedlings can be recommended. Avoid excessive watering and crowding of the remaining plants.

THE JERUSALEM ARTICHOKE.

FOR nearly three hundred years the plant known to botanical science as Helianthus tuberosus has borne, in English gardens, the name of Jerusalem Artichoke. In these latter days, when many established beliefs are in the melting-pot, the claims of this appellation are being questioned, and efforts are being made to substitute another name, more descriptive and more truthful. Incidentally, the discussion has widened into an inquiry upon the subject of the introduction of the plant into this country, but has done little beyond disclosing how little is known as to its origin.

Botanists have long occupied themselves with this same question, and the names of Asa Gray, Decaisne, De Candolle, and Schlechtendal will readily occur to the mind in connection with this interesting point of historical research. The care, however, with which these eminent scientists have delved into the past has produced a negative rather than a positive result, in that they have all come to more or less the same conclusion that historical evidence of the origin and introduction of the Jerusalem Artichoke is almost unobtainable, and that tradition varies so greatly as to be entirely untrustworthy.

It appears evident, however, that the plant is a native of the United States or of Canada (the term "Canada" in the seventeenth century often included what are now known as the United States). Travellers at the end of the sixteenth and beginning of the seventeenth centuries used to tell of a native American plant the roots of which were eaten by the "Indians," and which tasted like the Artichoke. At that time the Potato was so little known in Europe that travellers from this continent frequently confused the Potato with other plants of which the tuber was eaten, thus considerably increasing the confusion in the nomenclature of the Jerusalem Artichoke. It seems fairly evident, however, that where a "taste of the Artichoke" is mentioned, the plant referred to is Helianthus tuberosus, as by no stretch of imagination could such a flavour be ascribed to the ordinary Potato. It is, however, this confusion which has led to one of the earlier names of the Jerusalem Artichoke, namely, "Battatas of Canada"; it is under this name that it is mentioned, in 1629, by Parkinson in his *Paradisus*.

The traditional origin of the French name Topinambour is so slight that one would hesitate to give it, were it not that it is supported by the authority of Monsieur Georges Gibault, the indefatigable librarian of the French Société Nationale d'Horticulture, in his *Histoire des Légumes* (1912). It would appear that in 1613, the approximate year of the introduction of the Jerusalem Artichoke into France, a little party of the savage inhabitants of the isle of Maragnon, Brazil, was brought to France as a curiosity. These natives were called by the French "Toupinambaux," which designation is apparently a corruption of the name "Tupi Guarani," by which they were known to Brazilian settlers. The coincidence, therefore, of the introduction of the "Topinambaux" and of the strange, new tuberous vegetable led to the tubers being called by the name of the savage visitors (afterwards still further corrupted to Topinambaux and Topinambours), though there is not the least evidence that the Topinambour was ever grown in Brazil, or that these particular savages ever ate it!

The name Topinambour, which falls so pleasantly and trippingly from French lips, and was willingly adopted in other (chiefly Latin) countries, did not find favour with the English. The vegetable was introduced into this country in 1617 by a Frenchman, Monsieur Francqueville, resident in London. It seems, therefore, reasonable to suppose that it must have come to us first under its quaint French name; but already in 1629 we find Parkinson describing it under the name of Battatas of Canada. In 1640, however, in the same author's *Theater of Plants*, there occurs, probably for the first time, the name by which it has ever since been known to us, Jerusalem Artichoke.

How did Parkinson arrive at this extraordinary name? Certainly he did not think the plant was a native of Palestine, for he himself had previously named it "of Canada." In order to obtain some light upon the subject we must go to Italy, which country had also, by this time, received the new vegetable, and had adopted it with some readiness. It was, in fact, introduced into Italy before it was known in this country, namely, some time before 1616; tradition says, from Peru, though it has never been found to be indigenous to that country, or to any part of South America. However that may be, it seems certain that it was not introduced into Italy through France, but direct from America. The Italians would thus be under no temptation to use the French name, but would name it for themselves—which they accordingly did, by the beautiful name of "Girasole" "Turn-as the sun." Now, it is quite probable that between 1629 (when Parkinson wrote his *Paradisus*) and 1640 (the date of publication of the *Theater of Plants*), when English gardeners appeared to have finally accepted the name of Jerusalem Artichoke, the Italian name Girasole had become known in this country. Topinambour, if ever used, had long been abandoned, owing probably, as before suggested, to the difficulty of pronunciation; "Battatas" would have been found impracticable, on account of the growing popularity of the true Potato, with which, if it bore a similar name, the new tuber would have been hopelessly confused; what, then, more natural than to adopt the simple Italian name of "Girasole"? Once adopted, it would share the fate of the majority of imported words; its meaning unknown to the greater number of people who used it, the word would immediately become converted to something that *was* known. English pronunciation, we know, has changed considerably in the past three hundred years; and what little we know of the rules it has followed would lead us to infer a still closer resemblance in 1640 between the words "Girasole" and "Jerusalem" than exists to-day.

Having arrived, then, at the word "Jerusalem" (which would be considered in the light of an adjective), some noun would be sought to tack on to it. The word "Artichoke" would naturally be chosen to fill this hiatus, on account of the taste of the new vegetable, which was considered to resemble that of the inflorescence of Cynara.

A correspondent who has written so interestingly in these pages on this subject over the initials *H. E. D.* mentions the name "Tartufoli" as a synonym for Girasole. But Monsieur Gibault (*op. cit.*) differs from him, and I am bound to say I agree with Monsieur Gibault when he says: "La plante appelee Tartufli, truffe, . . . décrite par Olivier de Serres en 1600, n'est pas le Topinambour comme Parmentier l'a cru. . . . C'est la Pomme de terre."

We may mention one more so-called synonym on which there appears also to have been some confusion. Lescarbot, who was one of the earlier colonists in Canada, writes in 1618 deprecating the use of the foolish name "Topinamlaux," stating that the natives of Canada called the vegetables in question "chiquebi." Monsieur Lescarbot tripped, however, in making this statement; the name "chiquebi" was applied by the Algonquins only to the tubers of Apios.

As an example of the danger of loose derivation, and of the habit of mind known to philosophy as "rationalisation," we give one quotation from the writings of De Combles, 1749. He wrote (at a time when the French taste for Jerusalem Artichokes had considerably declined): "Voici le plus mauvais légume dans l'opinion générale; cependant

. . je dois . . . placer ce légume avec les autres. Les fruits (tubercles) sont de la grosseur d'un oeuf; cette plante est venue d'Amérique, *du pays des Topinambours, d'où elle tire son nom.*" The italics are my own, but are scarcely necessary to point the moral to us, who know on how slight a foundation rests the assertion contained in those words.

The subject of popular nomenclature forms one of the most fascinating of studies; the pity of it is that too much of the evidence on which, *faute de mieux*, we must rely, is either altogether erroneous or in the nature of the extract given immediately above. *M. E.*

ORCHID NOTES AND CLEANINGS.

ODONTOGLOSSUM VICTORY VAR. THE BARONESS.

By the use of a specially selected hybrid of perfect shape—of which the parentage is not known—for crossing with Odontoglossum crispum The Baroness, Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, have raised a specially fine race, which they have named their "Victory" strain. The first of these hybrids was shown at the Royal Horticultural Society's meeting on October 12, 1915, and was awarded a Preliminary Commendation; the variety was described in *Gard. Chron.*, Oct. 16, 1915, p. 253. Since that time several forms of the batch have been shown, all bearing the same characteristics of perfect shape and remarkably firm substance as in the original cross. The variety The Baroness, illustrated in fig. 81, is the latest of these hybrids which has flowered, and shows the perfection of all the floral points aimed at by the hybridist. The ground colour is white, the markings rich Indian red with a shade of orange colour.

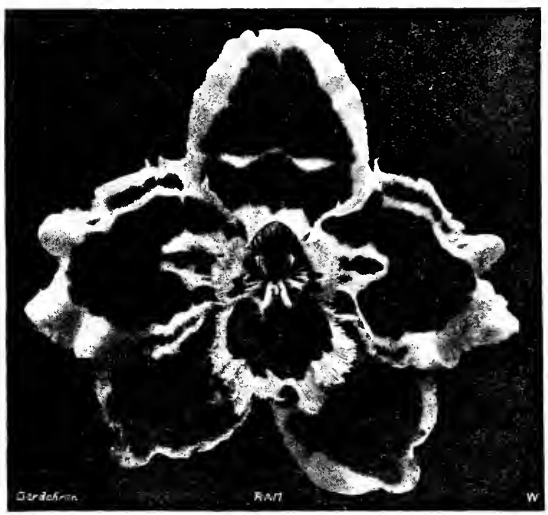

FIG. 81.—ODONTOGLOSSUM VICTORY VAR. THE BARONESS.

BRASSO LAELIA JESTER.

A flower of this cross between Laelia Jongheana and Brasso Laelia Jessopii (L. xanthina × B. Digbyana) is sent by Pantia Ralli, Esq., Ashtead Park, Surrey (Orchid grower, Mr. W. H. White), in whose gardens it was raised and is flowering for the first time. The flower, which is nearest in form to B. L. Jessopii, shows little of the Laelia Jongheana parent, except in the golden-yellow disc of the lip and the undulation of its fringed margin. The sepals and petals are sulphur-yellow with a slight tinge of rose colour on the tips of the petals and the margin of the lip, the colour on which is much more highly developed on one side than the other, and scarcely perceptible on the lighter side.

ODONTIODA LEDA.

An inflorescence of this bright scarlet Odontioda of medium size, sent by Eustace F. Clark, Esq., Eversholt, Dorsetshire, is specially interesting in that, although in the ancestry there are several blotched Odontoglossums, the flowers on the spike sent give not the slightest trace of markings. In the slender habit and colour of the flowers, and especially the form of the lip and its yellow crest, the hybrid closely adheres to C. Noezliana, differing mainly in its larger flowers. The purple colouring on the back of the column of C. Noezliana is also visible in the hybrid. Oda. Leda was raised by Messrs. Sander and Sons, who first flowered it in 1914. It resulted from crossing C. Noezliana and Odm. Rio Tinto (gandavense × sceptrum).

SOPHRONITIS GRANDIFLORA.

Several brilliant scarlet examples of this compact-growing little species were shown at the Royal Horticultural Society's meeting on the 23rd ult., the bright colours of the flowers contrasting pleasingly with the variously tinted Odontoglossums and other Orchids in neighbouring exhibits.

Mr. W. H. White, Orchid grower to Pantia Ralli, Esq., Ashtead Park, Surrey, sends several examples of the bright scarlet flowers produced in pairs, and not singly, as is usual in the species. The production of twin flowers has frequently been recorded, and usually in favourable seasons by plants well grown in a cool or cool intermediate house and suspended near the roof-glass. The production of two flowers is said to be more frequent with some plants than with others.

ORCHID SALES.

The sale by auction of the Orchids in the collection formed by the late O. O. Wrigley, Esq., Bridge Hall, Bury, took place on April 16 and two following days. The buyers, chiefly amateurs, showed keen interest in the sale. The next event of the kind will be the sale of the extensive collection belonging to the late Mr. John Leemann, Heaton Mersey, near Manchester. The sale will be conducted by Messrs. Protheroe and Morris, on Tuesday, May 14, and three following days. The collection is rich in hybrids and named varieties of species.

ON CALORIES.

(*Concluded from page* 173.)

We must now turn to the other side of the question and seek to discover how many calories are required to enable a man to do the day's bodily work. The caloric requirements will, of course, depend on many factors, of which some of the chief are amount of work done, age, weight, and sex.

So far as sex is concerned caloric experiments carried out in different countries indicate that a woman's requirements are, on the average, about 30 per cent. of those of a man. But a complication comes in when age is considered, for whereas persons of all ages require food, not only for work-doing purposes, but also for repair of tissues, youth, the period of construction, requires more of the repair and constructional foods—that is, the proteins. Hence, in any system of rationing provision must be made for supplying young children with sufficient tissue building foods.

Again, the energy consumed per day will manifestly depend on the quantity and *intensity* of the work done. Even during sleep, energy derived from the combustion of food is required to keep the bodily machine running; but since all that energy, needed for the pumping of blood through the body, the pumping of air in and out of the lungs, ultimately runs down as heat, it helps to maintain the temperature of the body. This latter work, however, that of keeping up the temperature of the body, is always a first charge on the energy obtainable by the combustion of food. When violent exercise is taken all the heat energy produced cannot be used, and the body automatically takes steps to use up the surplus heat-energy by promoting perspiration. The heat energy is used to evaporate water from the surface of the skin.

Therefore, violent work is extravagant of fuel; in other words, men engaged in heavy manual work use more calories than those engaged in work of average heaviness, and these in turn use more than those in semi-sedentary or sedentary occupations. Hence a scientific system of rationing must be based not only on age and sex, but also on occupation.

There are several means by which caloric requirements may be ascertained.

One, which is the best, but most laborious and difficult, is to measure the work done by an individual, and at the same time to determine the energy value of the food supplied. By experiments along these lines it has been found that, as already stated, about 30 per cent. of the energy supplied by the heat units of the food may be used for the day's work. Accepting this fraction it is possible to say that if the day's work of a man requires so much energy, he must be supplied with food sufficient to provide 3⅓ times as much energy.

Another experimental method of ascertaining the number of calories required is to measure the total output of energy in heat units (calories). Experiments made in this way have shown that in the case of a metal filer working at a known rate 3,656 calories were liberated (and therefore consumed) in a day, 8 hours of which were devoted to work, 8 to "rest," and 8 to sleep. Evidently if we had sufficient experimental evidence of this kind we should have a complete answer to our question; but we have not. Recourse must therefore be had to a third and less satisfactory method, that of collecting statistics with respect to the amount of food consumed, from large numbers of people belonging to one or other section of the community. In spite of the somewhat unsatisfactory nature of this indirect method, the results obtained in different countries and by many different observers, are very concordant. Thus the daily diet of a large number of English agricultural families was, on the average, composed of: Proteins, 3 oz.; fats, 3 oz.; and carbohydrates, 19 oz., representing a total of about

3,500 calories. The average diet of some 18,000 English munition workers proved to be: Protein, 4 oz.; fat, 4⅔ oz.; and carbohydrates, 14 oz., with a total caloric value of 3,460. Evidently bread, which makes so large a contribution to the agricultural worker's diet, was replaced in the case of the munition workers by an approximately corresponding amount of proteins and fats.

From these and other statistics it may be inferred that a grown man of average weight (150 lbs.), doing moderately hard work, requires 3,500 calories per day. As the work done increases or decreases, so the caloric requirements rise or fall very rapidly. Thus, for very active physical work about 4,500 calories per day are required, and this number rises in extremely hard work to 5,000. On the other hand, for light sedentary work no more than 2,500 calories a day are required, and those who do no active work whatever use no more than 2,300 calories.

With the table already provided in which the composition of the various foodstuffs is given anyone may work out for himself the amount—and at current prices the cost—of a sufficient ration. To do this a reduction of 12 per cent. on the caloric value of food "as bought" should be allowed for waste in cooking, in cut preparation and digestion.

It is also easy to calculate the number of calories contained in the rationed diet, and thus to ascertain the number which must be supplied from non-rationed articles.

Other points, however, require to be borne in mind by anyone who desires to base his diet on the ascertained facts relating to the human machine. One is that if food is of a very low grade—as, for example, in the case of horses poor hay—it may require so much digestive work to be done on it that the food if used alone, although it will keep store animals alive during rest, will not suffice for working animals.

Moreover, in addition to heat producing and tissue building foods, the body requires a sufficiency of mineral salts and of what may be called natural preventive medicine foods. These latter substances, known commonly as vitamines (see *Gard. Chron.*, December 22, 1917, p. 251), occur naturally in eggs, milk, and in fresh vegetables, and are essential for the maintenance of the health of the body. Hence every diet should comprise some of the vitamine containing food stuffs, although the quantity required is extremely small. A diet, for example, which is made up exclusively of canned foods is likely to be followed by signs of malnutrition and disease. The claims of fresh vegetables to a regular place in the diet are based on the fact that they are rich both in mineral salts and also in vitamines. To obtain the full value from these foods it is essential that they be properly cooked. If vegetables are cut into pieces and immersed for a long while in water, much of the "goodness"—that is, the mineral salts, and probably also the vitamines is dissolved and lost. Herein lies the advantage of vegetable soups, so popular among the thrifty peasants of France and Belgium.

NEW OR NOTEWORTHY PLANTS.

EUCOMIS POLE EVANSII, N. E. BR.*

It is interesting to note how certain genera have in some way appealed to the gardener, have gained his favour, have been modified and improved by his methods of selection and hybridisation, and have emerged from the process to become general garden favourites. Other genera that would seem equally to merit the consideration of the horticulturist have, from some cause or other, been neglected, with the result that they are not so frequently seen in cultivation as their worth might cause one to expect. Among such may be ranked the South African genus Eucomis, of the order Liliaceae. Some species of this genus have been in cultivation off and on for more than a hundred years, and one species for over two hundred years, yet they remain to-day as when first introduced. They are bulbous plants that never seem to have become popular, possibly because their flowers are not brightly coloured. Yet they are decidedly striking in appearance, and more or less ornamental in somewhat stiff looking. The tuft of small leaves which terminates the flower spike is their most striking characteristic, whilst the stout, dense spike of moderate sized flowers, although not brilliantly coloured, is by no means unattractive. All the species hitherto described range from about 1 foot to 2½ feet in height, but about three years ago Mr. I. B. Pole Evans, chief botanist to the Department of Agriculture, Pretoria, found growing along the edges of small streams on the high veldt between Lydenburg and Machadadorp, in the Transvaal, an undescribed species that is the most gigantic of all Eucomis at present known. Mr. Pole Evans sent living bulbs and dried specimens of the plant to Kew, accompanied by the photograph reproduced in fig. 82 of the plant as it grows in the grounds attached to the Laboratory at Pretoria. The illustration shows an ornamental plant of noble proportions: the fully developed flower stem is 5·6 feet in height, forming a large spike of cream-coloured flowers. The newcomer should prove a welcome addition to our half hardy plants, but it would probably not survive our winters if treated as hardy.

Specifically it is allied to E. pallidiflora, but is twice as tall; the leaves are longer and broader; the pedicels longer and much more spreading; the perianth cream-coloured, instead of greenish white; and the ovary straw-yellow, instead of green. I have a suspicion that this species has been introduced once before and wrongly supposed to be E. pallidiflora, but I have no knowledge that it still exists in cultivation. The following are its characters, partly compiled from particulars sent to me by Mr. Pole Evans, after whom I have great pleasure in naming this very fine plant.

Bulb ovoid, up to 4 inches in diameter. Leaves 9-12 to a bulb, 2½-4 feet long, 4-7 inches broad, ascending, broadly strap shaped-lanceolate, subacute, channelled along the midrib, undulated along the margins, soft in texture. Flower stem 5-6 feet in total height, with the peduncle about 4 feet long and an inch thick, light green; the raceme 12-18 inches long and 3½-5¼ inches in diameter, lax below and dense above, with a tuft

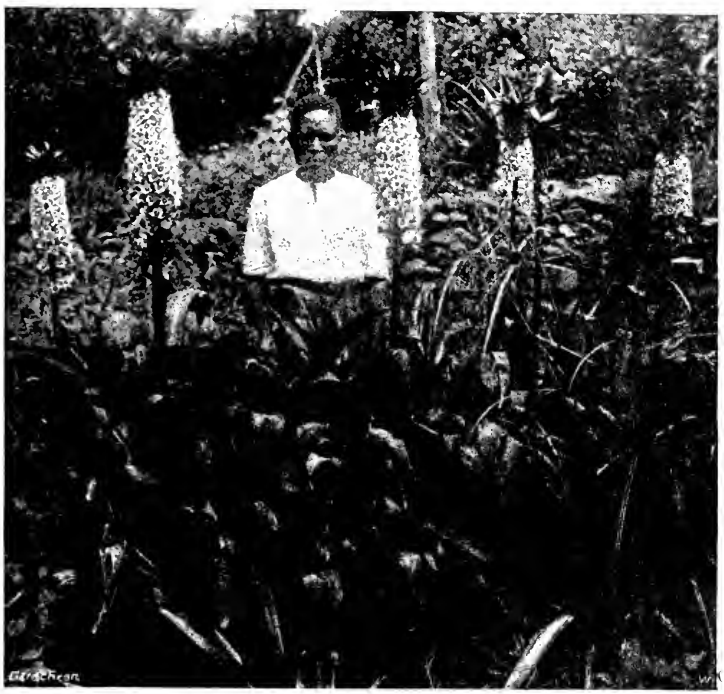

FIG. 82.—EUCOMIS POLE EVANSII GROWING IN THE GROUNDS OF THE BOTANICAL LABORATORIES OF THE UNION, PRETORIA.

of 23-90 small leaves at the top. Bracts about ⅛-¼ of an inch long, lanceolate, acute. Pedicels 1¼-2 inches long, spreading or slightly ascending, spreading. Segments of the flower ⅜ of an inch long, elliptic ovate, sub obtuse, cream coloured. Stamens shorter than the perianth segments, with the filaments dilated at the base and forming a distinct cup, green. Ovary globose conical, straw yellow.—*N. E. Brown.*

* *Eucomis Pole Evansii* n. sp. N. E. Br. Bulbus ovoideus, 10 cm. diametro. Folia 9-12, adscendentia, 75-180 cm. longa, 10-18 cm. lata, late lanceolata, et costam canaliculata, undulata. Pedunculus 120 cm. longus, 2½ cm. crassus, viridis. Racemus 30-47 cm. longus, 9-13 cm. diametro, Coma 23-90 foliata, foliis oblongo lanceolatis acutis. Bracteae 1-1½ cm. longae, 1-6 mm. latae, lanceolatae, acutae. Pedicelli 3-5 cm. longi, patuli. Perianthi segmenta 15 mm. longa, elliptico-ovata, subobtusa, pallide flavo alba. Stamina 10 mm. longa; filamenta basi dilatata viridia. Ovarium conico-globosum, in stylum abrupte attenuatum, stramineum.

sunny places the plant colours well, and is a fascinating subject for the rock garden. I believe the variety was brought by the late Mr. Potts, of Edinburgh, from Vienna a number of years ago and introduced by him to several gardens.

IONOPSIDIUM ACAULE.

IONOPSIDIUM ACAULE, the Violet Cress, is particularly suitable for the shadier nooks and corners of the rock garden. Growing only an inch or two high, it gives brightness and attractiveness to places where a few miniature flowers are welcome in late summer and autumn. The plant has glossy leaves and small, pale, violet-blue flowers. In a shady spot it blooms for a long time, and frequently sows itself for another season. Sown in the open from the middle of April to the end of May, the seedlings if well thinned soon reach the flowering stage. *Index Kewensis* refers it to Cochlearia and gives its name as C. acaulis, but the name of Ionopsidium has been long established in gardens. Maund, who called the plant Ionopsidion acaule, stated that according to the *Botanical Register* the plant was received by "the London Horticultural Society from the garden of the Duc d' Palmella, near Lisbon, in 1845. It is said to be found wild on the basaltic hills, near Lisbon, and occasionally on the limestone formation of Estramadura." *S. Arnott.*

NOTICES OF BOOKS.

THE FLORA OF MADRAS.*

THE families dealt with in this part of Gamble's *Flora* are eleven in number, and, apart from the Papilionaceae, mainly composed of woody elements. Celastraceae and Rhamnaceae are represented by nine and eight genera respectively, showing a relatively large concentration of these families; and Sapindaceae and Anacardiaceae by twelve and eleven genera, more than half by a single species each. The occurrence of a Maple, Acer niveum, is noteworthy. But the Papilionaceae constitute the bulk and important element of this part, comprising no fewer than 59 genera, some of them numbering many species. Thus 75 species of Crotalaria are described, 31 of Indigofera, 20 of Tephrosia, 12 of Smithia, 24 of Desmodium, 17 of Rhynchosia, 11 of Flemingia, and 15 of Dalbergia. Bentham and Hooker's classification is followed with slight modifications in the limits of some of the families. Each family is described in sufficient detail, followed by a key to the genera; the genera in their turn are described and followed by keys to the species. All is admirably and clearly set forth, and much less formidable than repetition of characters common to all the species of a genus. Vernacular names in several Indian languages are cited, and useful products are mentioned. Apart from well-known economic roots, timbers, fibres, oils, etc., there are references to other less familiar substances. For example: The root-bark of Ventilago maderaspatana gives a dye. Schleichera trijuga has an edible axil, and the seeds yield an oil; the best lac is produced on its twigs, and the hard, durable wood is used for rice-pounders. Buchanania Lanzan (Anacardiaceae) gives a copious gum, and the kernels of the seeds are largely collected and eaten, as well as those of B. lanceolata and B. angustifolia. The heart-wood of Gluta travancorica is dark red, mottled with orange and black streaks, and is valuable for furniture. Of Sesbania grandiflora the young leaves, flowers and pods are eaten as a vegetable, and the huge tubers of Pueraria tuberosa are sometimes eaten. *W. B. H.*

* *Flora of the Presidency of Madras.* By J. S. Gamble, C.I.E., M.A., F.R.S., late of the Indian Forest Department. Vol. I., Part 2, pp. 201–390. Celastraceae to Leguminosae Papilionaceae. Published under the authority of the Secretary of State for India in Council. (London: Adlard & Son and West-Newman, Ltd.) Price 8s.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey

FRENCH BEANS.—Make a first sowing of French Beans in a warm, sheltered position in double lines, in rows 2 feet apart, thinning out the plants later to 6 inches apart. These will follow plants grown in cold houses or frames. A few seeds should also be sown in 3-inch pots or boxes to replace any failures which may occur. A further sowing should be made in ten days' or a fortnight's time, to ensure a regular supply, and again as required. These plants are very tender, and must be protected as soon as they appear through the ground. A little extra attention at this stage may enable the crop to be gathered at least a fortnight earlier. Magpie, Dickson's Belfast, and Ne Plus Ultra may be sown for early supplies, with Canadian Wonder for general use later.

CLIMBING FRENCH BEANS.—These Beans are most productive, and will produce a continuous supply until late in the autumn. Give the plants a little more space, and support with Pea-sticks about 4 feet high. Otherwise treat as for the dwarf kinds. Veitch's Climbing and Tender and True are both prolific, and almost stringless.

RUNNER BEANS.—Seeds sown as advised in pots or boxes will now be growing freely. Continue to grow the plants in such a manner as to keep them sturdy, but protecting them from frost, and plant them out towards the end of the month. Stake the plants at once, to prevent their being injured by rough winds. Sow seeds on well-prepared trenches in double lines 9 inches wide, and allow from 6 to 8 inches between the seeds. Protect the plants as soon as they appear through the ground, and dust with lime and soot, or slugs will quickly destroy the crop.

BEET.—The principal sowing may be made at the beginning of this month on deeply dug ground. Let the rows be 15 inches apart, thinning the seedlings later to not less than 6 inches apart. To obtain exhibition specimens boring must be resorted to, and a little more room allowed; but very large roots are not desirable for ordinary use. Dell's Crimson, Sutton's Green Top and Pragnell's Exhibition may be relied on, with Crimson Globe for early supplies. Keep a sharp look out for sparrows, and dust the seedlings over with soot and lime as soon as they appear.

PARSLEY.—A sowing of this most useful herb should now be made, making a further sowing later to keep up a good supply. Select an open position in a convenient place on well prepared ground, thinning the seedlings later to 6 or 8 inches apart. Champion Moss Curled is a hand some variety and a good grower.

GENERAL REMARKS.—Continue to sow seeds of such plants as those recommended in previous Calendars. There is still time to make good any failures which have occurred. Use the hoe frequently among all spring crops in favourable weather, and apply light dressings of soot when the weather is showery. Allow plenty of air to Peas, Beans, Turnips and Carrots growing in frames when the weather is favourable, and harden off seedlings in readiness for planting out later. Early Potatos in warm positions will now require daily attention to keep them covered with soil as long as possible. A few branches of Spruce may also be placed around them.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

PHALAENOPSIS.—Phalaenopsis Schilleriana, P. amabilis grandiflora, P. Stuartiana, and others that have recently passed out of flower, are now becoming active at the roots. These plants should be given fresh rooting materials each year. A suitable compost is made up of equal parts A1 fibre and Sphagnum-moss chopped rather short. Any Teak-wood baskets that are decayed should be replaced by new ones. When removing the plants, first immerse the basket in tepid water for a short time, which will cause the roots to be more easily detached from the wood. The wires that hold the basket together should be cut, and the bars of wood removed singly. Carefully detach the roots with the blade of a thin knife, wash away all the old compost, and remove dead portions of the roots. Before placing the plant in the basket, half fill the receptacle with portions of Fern rhizomes or clean crocks for drainage purposes. The roots should then be inserted singly between the bars, working the compost between the roots until it is level with the top of the basket. Finish with a layer of clean Sphagnum-moss. If the baskets are in a sound condition, carefully remove all the old rooting materials from between the roots, and afterwards wash the inside of the basket and roots by syringing with clean tepid water, filling up the spaces with fresh compost. These plants may also be grown successfully in shallow pans, preferably without side holes. Employ clean crocks for drainage, and a similar compost to that recommended for the basket plants, with an addition of some crushed crocks and small lumps of charcoal. Phalaenopsis plants should be given a position in the warmest house, where a constant circulation of warm air can be obtained, and should be shaded from the sun's rays during the spring and summer months. The plants may either be suspended from the roof-rafters or placed on the stage on inverted pots standing in saucers of water. The surface of the compost should be watered sparingly with a fine rose until the roots have grown well into it, after which they may be given more liberal supplies. On the approach of winter, moisture should be afforded in reduced quantities. The plants should receive frequent fumigations with an approved vaporising compound in order to destroy insect pests. Plants of P. Rimestadtiana that are now coming into bloom should not be disturbed at the roots until after they have passed their flowering period.

THE HARDY FRUIT GARDEN

By JAS. HUDSON, Head Gardener at Gunnersbury House, Acton, W.

APPLES AND PEARS.—Many gardeners have had difficulty in obtaining sufficient labour in the pruning season for the past two years, and, in consequence, some trees have not been pruned. These trees are, in many instances, producing quite a good show for fruit, whereas the hard pruned trees that were more readily accessible have but a poor display. Possibly the increased root-action has had something to do with this result. Pears Louise Bonne of Jersey (double grafted), Williams' Bon Chrétien, Beurré Superfin, Beurré Diel, Pitmaston Duchess, Marguerite Marillat (also double grafted), and Thompson's, which did not yield well with us last season, are showing well this year. Among Apples, Blenheim Pippin was not at all remarkable with us for its crop last season, but this year the trees are showing well. These are tall trees, which used to be pruned, but have been left unpruned for two seasons. Now they are studded with flowers. Apples are, on the whole, showing very well, and the flowers are vigorous and healthy. Trees which were sprayed in February need not be sprayed again unless it seems necessary. Work of other kinds is very pressing, and increased food production calls for additional labour. These trees must, however, be watched in a month or six weeks' time for caterpillar attack. The recent rains have been beneficial in the case of soil which is shallow and rests upon gravel.

LATE-KEEPING APPLES.—Annie Elizabeth is a most useful late-keeping Apple. It is worthy of more consideration than it usually receives, and keeps until April in good condition. Newton Wonder also helps in providing a supply of Apples for dessert. When well coloured, moderately sized fruits of this variety are quite attractive. These late varieties have not kept so well for many seasons past. Belle de Boskoop and Royal Late Cooking are, as in past seasons, disposed to shrivel.

PEACHES AND NECTARINES.—The season is now at hand when aphis may be giving trouble.

A solution of Quassia chips and soft-soap is quite safe to use, and ought to be effective. Should the fly still be persistent, however, use liquid Gishurst Compound at the lowest strength advised by the makers. The specific should be thoroughly mixed with hot water, and cooler water added to make up the requisite quantity. The netting that has been used to protect against frost should now be removed in nearly every locality. If the soil appears to be at all dry, water the roots close to the wall. Where glass copings are used, watering is most essential at this season of the year.

PLANTS UNDER GLASS.

By E. HARRISS, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

FREESIA.—By careful attention to cultural details a good percentage of the bulbs which have flowered this season may be induced to flower again next year. Place the plants near the glass in a cool house in full exposure to the sun. Liquid manure may be afforded until the foliage shows signs of dying down; water must then be gradually withheld. Place the pots closely together in a cold frame and keep them quite dry. In August the bulbs may be shaken out of the soil and the most promising selected for potting, using a rich compost for this purpose.

TUBEROUS BEGONIA.—The young plants which have been raised from seed sown early in March should now be large enough to be pricked out. Prepare a quantity of seed-pans or boxes, filling them with a compost of loam, peat, leaf soil, and sand. Mix the soil firm, and prick out the seedlings about 2 inches apart. They must be kept growing gently in a moist, warm atmosphere, and sprayed lightly with tepid rain-water twice a day. When they are large enough to need another shift, they may be transferred to 5-inch pots to flower. Begonias require a little shade when grown under glass, but not too much. The blinds may be drawn up after closing the house in the afternoon.

CHRYSANTHEMUMS. Some of the earliest plants should now be sufficiently hardened to be placed out-of-doors. They must, however, be placed in a sheltered situation. Wattle hurdles make excellent screens for protecting plants from wind, and they should be so erected that a covering of tiffany can be thrown over them in case of frost. The large flowering kinds will now need stakes to prevent damage by strong winds. During favourable weather, the whole of the plants should be sprayed with rain-water twice a day, and as a precaution against aphis they should be sprayed with an insecticide once a fortnight. This should be done late in the afternoon, so that the specific does not dry too quickly. A batch of cuttings struck now will make useful plants for flowering in 6-inch pots. Single decorative varieties are especially useful for this purpose.

FRUITS UNDER GLASS.

By W. J. GUISE, Gardener to Mrs. DEMPSTER, Keele Hall, Newcastle, Staffordshire.

MUSCAT VINERY.—When Muscat vines commence to flower, a temperature ranging from 65 to 70 must be maintained at night. Difficulty in growing Muscats can usually be traced to insufficient heat at the flowering period, which prevents the fruits from setting, and leaves the bunches thin and straggling. During the daytime the thermometer may range from 85° to 90°, with a rather drier atmosphere. This will allow the pollen to ripen, and it can be distributed by lightly shaking the rods or tapping the wires. Gradually increase the top ventilation as the sun gains power, while a little air through the top ventilators at night will assist the development of the fruit. So long as the laterals do not touch the glass there need be no hurry in tying them down; the flowers will require all the light available. Directly the berries are set, atmospheric moisture should be increased and the house closed early in the afternoon, so as to raise the temperature to 90° by sun-heat. The paths and borders should be freely syringed just before the house is closed. Examine the borders, and if they are in need of moisture the opportunity should be taken to wash in a light sprinkling of Le Fruitier manure with tepid water, or to apply diluted liquid manure. Thin the bunches and berries in the early stages. Pinch the laterals two leaves beyond the bunches, and stop all sub-laterals at the first leaf. Muscat vines are very liable to scorching: in case of bright sunshine it is advisable to spray a thin mixture of lime-wash over the glass.

PEACH TREES IN POTS.—The early trees are now well through the stoning period, and more warmth may be provided, not by fire-heat, but by closing the house early. The trees will require frequent syringing. Vary the diet when feeding, for fruit trees readily respond to a change of food. Admit light and air wherever possible by periodically pinching the laterals. A drier atmosphere must be maintained when the fruits commence to colour, but, although syringing must be discontinued, the trees should not be permitted to suffer for lack of moisture at the roots. Ventilate the house freely, night and day, while the fruits are ripening.

FIGS.—Directly the fruits of early pot Figs show signs of ripening, a warm, dry atmosphere will be necessary to give the final finish and flavour. Syringing must cease, and only sufficient water be given to keep the plants in a healthy condition. The house may be damped down during the hottest part of the day, and every precaution taken to keep the foliage free from red spider. Cuttings rooted early this year will now require more root space, and should be shifted, or they will become pot bound. By careful pinching build up sturdy, short-jointed plants for fruiting next year.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HOPETOUN, Tyninghame, East Lothian.

SWEET PEAS.—Sweet Peas planted in pots or boxes should now be transplanted in the open. Give them an ample space. A dressing of superphosphate along the rows will give the young plants a fine start. Always provide supports from the outset, placing dead Spruce branches close to the plants, and outside the ordinary Pea-sticks.

SPANISH IRISES. These are now making rapid growth, and will require a surface dressing of soot, pigeon manure, superphosphate, and sulphate of ammonia. They should also be weeded, as weeds are growing among them for the last time. Last year I had a crop of early Potatoes from among the plants, and this year Broad Beans have been planted among them. The plants are too valuable for their flowers to be destroyed, and it does them no harm to crop among them, provided close cropping is not attempted.

EDGINGS.—Permanent edgings of Cerastium tomentosum will need hard clipping before the flowers are produced, to keep the plants thick and the foliage well coloured. An occasional slight trimming throughout the season will also be advisable. Hypericum calycinum used for a similar purpose also needs an annual cutting in to keep it neat; after a hard winter it may require to be cut to the ground. Aubrietias should be cut well in after flowering.

MIXED BORDER.—Now that the spring-flowering bulbs are over, a surface dressing of superphosphate of lime applied equally over all the border will be of much service to the later classes of border plants. Apply in dry weather, and run the Dutch hoe through all bare spaces immediately after sowing the manure. Seeds of annuals, plants of Pansies, Violas, Gazania splendens, Verbena verosa, Salvia patens, Lavatera Olbia, Chrysanthemums, and shrubby Veronicas may be used to fill vacancies, and all may be put in the border now, leaving spaces for tall Ageratums, Snapdragons (if not ready), Verbenas, Cuphea and Dahlias to be planted later.

HERBACEOUS PAEONIES. No delay should occur in placing the stakes by large herbaceous Paeonies and tying them firmly. The simplest and most effective method is to place the required number of stakes (five to seven) all round the plants, sloping outward, and tie a piece of stout string round the top of the stakes—one strand is sufficient. If once the shoots are beaten down by rain it is impossible to induce them to regain an upright position, hence the supports should be applied at once.

VIOLETS.—It is not yet too late to make new plantations of Violets, which, at least in the North, are not long past producing flowers. Quantities are grown here at the base of walls, and flowers are to be found sparingly from November until the usual flowering time in March. The Violet appreciates a liberal dressing of cow manure. Strong-growing varieties, such as Princess of Wales, should not be planted closer than 15 inches apart. Plenty of runners are available at this time for planting, further treatment being the application of water until new roots are made. Double varieties can be transplanted in autumn from the batch grown for forcing.

THE APIARY.

By CHLORIS

SWARMS AND SWARMING.—Where food is plentiful and the stocks are strong, early swarms may be expected. This generally happens where the Apple trees are in full bloom, usually from the middle or end of May or beginning of June. People who have never seen a hive at swarming-time are at a loss to know the signs. The first condition is a very crowded state; next, the presence of drones in plenty, and on examination queen cells may be found. Sometimes drone cells are mistaken by the beginner for queen cells. Worker and drone cells are horizontal; the former are the small ones, and number five to the inch, while the drone cells protrude further, and number four to the inch. Queen cells are generally found round the edge, or in a nook in the comb; they point downward, are much larger than the other cells, and when sealed are very much like an acorn in shape. On examining the hive, should the queen cells be capped, a swarm may be expected any fine day between the hours of 12 and 5 summer time. Rainy and cold weather will effectually prevent the issue of a swarm. In this case the more forward queen cells are often destroyed, and the occupants killed by the reigning queen. In some instances all the queen cells are destroyed and swarming abandoned for the whole season. When a swarm issues there can be no doubt about the fact, for the air in the vicinity of the hive is simply alive with bees. After the bees have flown to and fro for some time they begin to settle, often on some low-lying bough, but occasionally in almost inaccessible places. The first swarm rarely settles higher than some low bush, but later swarms, headed by the new queens, may settle anywhere, or even decamp. If the bees show little or no sign of settling, the process may be accelerated by using a syringe and driving the water high in the air over the bees to imitate a shower of rain.

HIVING THE SWARM. When a swarm has clustered, a little water from a syringe will make them cluster tighter. On the ground place a piece of cloth or a sack immediately below the bees, place the skep or other receptacle under the bees, give the bush or branch a sharp shake, and the bulk of the bees will fall into the skep. Those on the cloth will soon run into the over-turned hive, if plenty of open space be allowed by resting one edge of the skep on a brick or stone. If the day be hot, the bees should be sheltered from the sun by means of a leafy branch or an umbrella. They should remain until 6 or 7 p.m., when they will be ready for transfer to their permanent quarters. When bees settle on a wall they should be removed to the skep with a stout goose-quill. If they settle on a thick hedge, place the skep above the swarm and use a little smoke to make them rise.

HIVING.—Having fitted up the hive, with frames and foundation quite safely secured, place a board on the alighting board, cover it with a cloth, overturn the skep, and give the sides a sharp rap to dislodge the bees. They will soon run into the new home. Should the weather be bad, feed with honey or syrup, but if favourable put on some drawn-out shallow combs if the object be extracted honey, or drawn-out sections where comb honey is desired. There being no cells below, the bees will naturally go above, where cells are provided to store the gathered produce.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C

Editors and Publisher *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER, *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS. 41, Wellington Street Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAY 4—
Nat. Auricula Soc. (Northern Section) Ann. Ex., Manchester.

TUESDAY, MAY 7—
Roy. Hort. Soc.'s Comm. meet. Scot. Hort Assoc. meet.

THURSDAY, MAY 9—
Manchester and N. of England Orchid Soc. Ann. Meeting.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 50.7

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, May 2, 10 a.m.: Bar. 30.2; temp. 50.5°. Weather—Dull.

Food Substitutes.

A note in *Nature*, April 18, 1918, in commenting on a recent article in the *Illustrated London News*, entitled "Our Ill-fed Foes," makes the useful point that we should mark, learn, and digest (whenever possible) the food substitutes which are being used in enemy countries.

The excellence of Nettle-tops as a substitute for Spinach is well known. Dandelion leaves make one of the best of salads, and their ground and well-roasted roots are said to be a good substitute for Coffee. Properly cooked, Sorrel is—at least, in the opinion of the present writer—superior to Spinach; but to cook it properly either the water must be changed several times to get rid of the superfluity of oxalic acid, or it must be blended in a purée with a "softer" vegetable, such as Orache. The Broad Bean tops usually pinched out and thrown away are, in the opinion of many, as good as Asparagus. The present scarcity of food is bound to lead to the systematic collection of many of the tuberous and rhizomatous plants, many of which are rich in starch, and it may well be that if we insist on stiff collars and shirt fronts we shall have to get them starched by means of the meal from Lords and Ladies or from the water Flags.

The nation is at last alive to the incredible thriftlessness which general pre-war cheapness had begotten.

A national Autolycus—the snapper-up of unconsidered trifles—is already at work under the euphonious title of the National Salvage Board. Already thousands of tons of fat which formerly was put to the nugatory use of choking sinks is being recovered and put to profitable use either for food or munition purposes, and as a result of this belated thrift vast quantities of glycerine—indispensable for the manufacture of explosives—have been produced.

Diseased Potatos, where not wanted for pig food, are, we believe, to be used for the manufacture of alcohol; and we know that the Horse Chestnut harvest of last year was garnered in order to serve as material for the manufacture of an essential munition of war. Even bacteria are being trained to scavenge for the benefit of mankind, and in particular to manufacture one of the food substances of which at present we have none too much.

Messrs. Lowe and Shawyer, of Hounslow, are setting an admirable example in economy by using peat to absorb night soil, and are preparing therefrom what is evidently a valuable and perfectly inodorous fertiliser to supplement the decreasing supplies of farmyard manure. Household waste collected by the Boy Scouts at Ilford is being supplied to farmers as supplementary food ration for pigs, and many municipalities are undertaking pig-keeping—bringing, as it were, the pigs to the only remaining plentiful supplies of food. The waste of the Liverpool market is, we believe, dried and made into food for stock, and thanks to the enterprise of Professor Barker, of Long Ashton, the Food Production Department were able last year to arrange for some of the Cider makers to convert pomace into cattle food, and surplus cider Apples into Apple jelly.

Certain seaweeds, long used by the Germans—and sometimes by others—to form a jelly basis for jam, are now being collected and used as substitutes for gelatine. In Germany Tobacco is made from Hops and Beech leaves, but it is said in the note above referred to that the best substitute Tobacco is made from dried Coltsfoot leaves; the new Budget may therefore compel some of us to resume the vasculum of our youth and collect Coltsfoot wherewith to smoke the pipe of war. Even cigars—suitable, we presume, for presentation—may be made therefrom.

The thrifty Belgian—an excellent judge of food—esteems highly the young shoots of the Hop. Well cooked, they make a dish the equal of Asparagus. Edible fungi have long been used and esteemed as food, and doubtless wherever in any locality there is to be found a person both enthusiastic and knowledgeable, the countryside can be made to provide many a cuponless meal, and not only the countryside but the seashore. Indeed, it would not be a bad plan to require of every visitor to the sea that he should catch one meal a day, for the harvest of the sea is, of all harvests, the most bountiful; and even close round our shores will yield much to the gleaner as well as to the professional reaper.

Some of our museums are doing excellent work in holding exhibits of native edible weeds; and if demonstrations on how to cook them were also to be given periodically, those whose thriftiness is awakening under the stress of scarcity would be very grateful.

If we were not all Directors nowadays, we would venture to suggest that a Director of Food Substitutes should be appointed, with the condition that he should act as the people's taster: sample what he preached, and not, like Redi, "never drink the wines he vaunted" . . . We invite our readers to contribute to the list of food substitutes in order that the knowledge possessed by the individual may be made available to all.

BOTANICAL MAGAZINE.—PAEONIA PEREGRINA, TAB. 8,742.—This handsome, scarlet-flowered Paeony has several synonyms, including P. lobata, P. decora, and P. romanica. The *Botanical Magazine* states that Baker described the plant in *Gard. Chron.*, 1897, Vol. XXII., p. 10, under the name of P. decora, but this is an error, and we can find no reference to the plant in any of the issues of the year mentioned. Miller, who is the authority for the name, does not seem to have been closely acquainted with the plant, for his herbarium sheet under the name P. peregrina bears two small specimens, both differing, of which one appears to be P. monticola, figured in the *Bot. Mag.*, tab. 1,050, as P. peregrina. The confusion is probably due to Miller's having only known the plant from figures given by earlier writers. The species is a native of the Balkan peninsula, and does not appear to be common in English gardens. As it flowers profusely and is easy of cultivation, it would be very suitable for the herbaceous border.

PTERIDOPHYLLUM RACEMOSUM. TAB. 8,743.—Pteridophyllum is a monotypic genus, the solitary species of which is a native of the mountains of Central Japan. The plant has proved quite hardy at Kew, and the Fern-like foliage is its most decorative feature. The inflorescence, forming an erect raceme, with small, rounded white flowers, which soon drop, is apparently too fugitive to be a conspicuous feature.

MACODES SANDERIANA. TAB. 8,744.—This handsome Orchid was first described by Kraenzlin in *Gard. Chron.*, Oct. 26, 1895, p. 484, under the name of Anoectochilus Sanderianus. The ovate, crenulate leaves are reticulately veined with yellow on a greenish-brown ground.

INDIGOFERA PENDULA. TAB. 8,745.—A new Chinese Indigo, first found by the late Abbé Delavay in Yunnan, China. In May, 1906, Mr. Geo. Forrest sent home seeds, some of which were raised at Kew. The raceme of flowers is about 18 inches long, and the pinnate foliage is nearly as long. The species appears to be as hardy as other cultivated Indigoferas, and may be easily increased by means of cuttings.

AGAVE FOURCROYDES. TAB. 8,746.—This is an old garden species, and has been known under various names. It was described by Baker in *Gard Chron.*, Sept. 29, 1877, p. 397, under the name of A. Ixtli var. elongata. The plant is a native of Yucatan, and yields a valuable fibre resembling Sisal hemp. The tall, pyramidal inflorescence is composed of bunches of greenish-yellow flowers.

RHODODENDRON PROSTRATUM. TAB. 8,747.—A charming little Rhododendron from China forming a prostrate shrub 2 to 4 inches high, with a trailing habit, which renders the plant suitable for the rock garden. It is described as one of the most distinct and beautiful of the dwarf Rhododendrons in cultivation. The flowers are mauve-pink.

ECHEVERIA SETOSA. TAB. 8,748.—This new species, which is readily distinguished by the setose leaves, was discovered in 1907 by Dr. Purpus in Southern Mexico. It is tender, and

needs greenhouse cultivation in this country. The plant flowers regularly, producing arching spikes of dark red flowers tipped with yellow.

PETUNIA INTEGRIFOLIA. TAB. 8,749.—Commonly known in gardens as P. violacea, this species has proved a veritable trap for botanists, who have given it at least nine names under five different genera. In consequence of the confusion which reigned, the Kew authorities made frequent attempts to obtain the importation of the true species from South America, and were at last successful in obtaining seeds. The flowers are attractive, being bright rosy-purple, which, however, becomes paler with age. The plant is as easy of cultivation as the majority of Petunias raised from seed.

RHODODENDRON BRACHYANTHUM. TAB. 8,750.—A small-flowered, yellow species, regarded by some botanists as a form of R. sulphureum. The species was discovered by Mr. GEO. FORREST in China, and specimens, raised from seed sent home by him, flowered in Mr. J. C. WILLIAMS' garden at Caerhays. The plant does best in partial shade, and so far has proved hardy.

ASPARAGUS FALCATUS. TAB. 8,751.—A wild garden plant, which has been long in cultivation in gardens in this country, and sometimes confused with A. Sprengeri. Both species have flattened cladodia and racemose inflorescences, but in A. Sprengeri the cladodia are straight and not falcate. A specimen in the temperate house at Kew, forms a screen 30 feet high, clothing a staircase at the northern end of the building. The flowers appear in June, and their honey-like fragrance pervades the whole building.

NARCISSUS CRIMSON BRAID.—Modern developments in the Daffodil have broken down the dividing lines between what were formerly very distinct groups of these beautiful spring flowers. True poeticus varieties are numerous, and every year cross-breds between Poets' and Barrii Daffodils are shown by raisers, and in the majority of these hybrids the tendency seems to reduce the Barrii and exalt the Poets' varieties. Messrs. HERBERT CHAPMAN, LTD. have been successful in obtaining choice varieties, and their Crimson Braid, illustrated in fig. 83, though classed as Barrii is much nearer the Poeticus section. It is a flower of beautiful form, firm texture, and rich colouring, whilst the plant appears to have plenty of vigour, giving promise of being a useful market variety. The perianth segments are regular in outline, rounded, and deep, solid, glistening white, while the cup is apricot yellow with a deep rim of rich, bright crimson of the tone known as mandarin red. The frilling or plaiting of the cup and its wide rim of deep colouring doubtless suggested the descriptive name of Crimson Braid. The Narcissus Committee of the Royal Horticultural Society gave the variety an Award of Merit on the 23rd ult. and it had previously received an award at Birmingham.

KEW GUILD JOURNAL.—The *Journal* of the Kew Guild for 1918, though very rightly abridged in these days of paper shortage, is nevertheless as interesting as usual. The frontispiece is a first-rate portrait of Mr. J. A. GAMMIE, the President-elect for the present year, whose extraordinarily good work in regard to Cinchona cultivation in Sikkim is described by the Director of Kew, Sir DAVID PRAIN, in an appreciative notice. Mr. GAMMIE was born on Kincardineshire on November 12, 1850. He was appointed in August, 1865, manager of the young and struggling Cinchona plantations in Sikkim. Not only was Mr. GAMMIE successful in overcoming the difficulties of cultivation, but in association with chemists in London he assisted very materially in designing the process of extracting as a mixed febrifuge all the alkaloids in the bark. This was, of course, before a method of separating quinine had been devised. Sir DAVID PRAIN says that but for Mr. GAMMIE the humane object of the Indian Government to place quinine within the reach of the poorest would not have been realised so early and so effectively as it was. After eleven years spent in working and improving this process, Mr. GAMMIE retired in 1897. Besides Sir DAVID PRAIN'S article there are a number of interesting letters from Kew men serving in the Forces, the letters collectively representing all the various "Fronts." We note that in 1915 three members of the Kew Guild were added to the "Roll of Honour," in 1916 six, and in 1917 seven. Obituary notes and portraits of those who lost their lives in 1917 are contained in the present issue. The editor, Mr. OSBORN, is to be congratulated on the excellent manner in which the interest of the journal is maintained.

DEVON PRODUCE SOCIETY.—At a meeting recently held at Exeter Castle, under the presidency of Sir HENRY LOPES, a society was formed under the name of the Devon Garden Produce Society, Ltd. For the first season the work is expected to be largely educative, consisting of guiding allotment holders and other small growers in their choice of which crops to grow and how to produce the maximum of food from the ground at their disposal. Local centres will probably be formed for the collection and disposal of surplus produce, but it is not intended that the society shall become a trading association in the ordinary sense.

PRICES OF FRUIT.—With a view to maintaining the production of jam the Food Controller has decided to fix maximum prices for all English-grown fruit required for this purpose. As it is not possible to fix these prices until some estimate can be formed of the probable crops in the country, the Food Controller gives notice of his intention to cancel any contract for home-grown fruit existing at the time when such Orders are issued, except in respect of deliveries completed before the date of the Order. It is also his intention to fix maximum prices for fruit pulp, after due regard has been given to the average price of fruit on the one hand and the controlled price of jam on the other hand.

WAR ITEMS.—Mr. C. RALPH CURTIS, the only son of Mr. CHARLES H. CURTIS, secretary of the British Florists' Federation and formerly editor of *The Gardeners' Magazine*, has been gazetted 2nd Lieut. in the King's Royal Rifles. Lieut. CURTIS, who before the war was with Messrs. JAS. CARTER AND CO., enlisted in the Coldstream Guards, and was on service in France with his battalion in 1915.

—— Mr. HUGHES, Floral Nursery, Kirkealdy, has received news of the death in action, on March 25, of his oldest son, Second Lieutenant WILLIAM HUGHES, Manchester Regiment. Lieut. HUGHES was in the Territorial Regiment of the Black Watch at the outbreak of war. He served at the Front for some time, and was afterwards gazetted second lieutenant in the Manchesters.

ON INCREASED FOOD PRODUCTION.

SEED-SOWING—ONIONS AND CARROTS.

IN these days of shortage of many things, including seeds, it behoves all engaged in horticulture to see that the maximum amount of produce is obtained from the seeds used. Waste of seed sometimes results from too early sowing. There is nothing gained by sowing weeks before the soil is sufficiently warm to promote germination. With regard to Onions, it is most important that seed should not be sown until the ground is in perfect order. The object in view should be to get the seeds well in a firm seed-bed, with a light, loose layer of soil above them. Moisture rises through the firm seed-bed to the point where the seeds rest, where it is arrested by the loose surface layer, which acts as a mulch. The seeds thus readily absorb the necessary moisture, while warmth and air are freely supplied from above. Where the whole surface is consolidated there is a danger of the top layer, which contains the seeds, becoming a hard, dry cake. We may learn much by carefully noting the conditions we obtain when sowing in boxes, which generally secure a good germination, and applying the same rules as far as possible out-of-doors. When sowing in boxes the best method is to fill with soil firmly almost to the top, secure a level surface on which the seed is sown, then, before covering, use the presser (a flat piece of wood) firmly, finally covering with a quarter of an inch of fine soil, left quite loose; this method secures the simultaneous germination of practically every seed. To apply this principle to outside sowing, the ground should be worked down (after any dressings of fertilisers have been applied), all lumps broken, and the whole consolidated, leaving the surface very fine and loose. The drills should be very shallow. After sowing the seed thinly, tread along the line, depressing the row sufficiently to admit of a covering of about a quarter of an inch of fine soil, which is brought into place evenly with the back of the rake. The nature of the soil should always govern the procedure, but the foregoing will suit especially those soils liable to form a cake on the surface, through which the slender growth of young Onions can not break, or, at least, do so very irregularly. With very light soils, treading, both before and after covering the seed, or even rolling heavily, is advantageous, but even then it would be advisable to use the rake lightly, as a loose surface, however shallow, tends to increase the moisture available to the seeds. Should dry weather follow seed-sowing, other small seeds, besides Onions, will germinate better if covered lightly with a loose layer of soil, but they must not be in this loose layer (which will quickly dry), but immediately below it.

Carrot-seed may be economised by mixing it with dry, fine soil, which prevents it from being blown away. Additional sowings may be made of the seeds thus saved on any available ground, none of which should be idle this year. Sowings of Carrots may be made at intervals up to the end of July, following other early crops. The late sowings will provide a valuable addition to supplies. Early varieties of the stump rooted sorts should be used. *S. A.*

CELERY.

SELECT an open, sunny situation for Celery where the soil is not too stiff, but it will not matter if it is poor, as rich soil is only needed in the bottom of the trenches. Poor soil answers well enough for earthing-up, and is generally free from worms. Make the trenches from 2 feet to 4 feet wide, to hold two rows. From 9 inches to 1 foot is a good depth. Put the soil up in neat ridges between the trenches, and plant the tops at once with Lettuce or sow with Spinach. The earliest-raised plants of Celery may then be put into the trenches. Dig a large quantity of manure into the bottom, then lift the plants with as much soil attached to the roots as possible, and set them well into the soil, watering thoroughly immediately the planting is finished. Late plants now in their seed quarters should be placed 2 inches or 3 inches apart in rich soil in a cool frame or under a handlight. Do not allow them to become dry at the roots, and ventilate the frame freely.

BEETROOT.

TWO mistakes are frequently made in growing Beetroots. One is sowing too early, and the other is putting the seeds in soil that has been recently and heavily manured. If the first sowing takes place within the present week it is quite early enough, especially if the soil has been well and deeply dug, selecting a plot which bore last year a crop to which manure had been supplied in fair quantity. Sow in drills at least 1 foot apart for all the medium-sized early varieties, but if larger sorts of the market type are grown, 15 inches should be allowed. Sow thinly, and as soon after germination has taken place as possible, remove the more weakly plants or those not required, leaving those for the crop at 9 inches apart. If growth is not satisfactory, encourage the plants with artificial manure, especially superphosphate and either nitrate of soda or sulphate of ammonia, the latter giving the better results in soils which contain a moderate amount of lime. *J. J. Price.*

SUMMER SAVORY.

HABIT or tradition allows dried Mint to appear on the table when Pea soup is served. We find that Summer Savory is preferable, or at any rate useful, for a change, and may be used to give a fillip, as the mood of the moment may determine, to a stew or hot pot. The sugar caster may thus remain in use in these days. Various blends of different dried herbs may be used. Summer Savory raised without heat is hardly ready for the first Broad Beans, and what self respecting cook will serve Broad Beans if she is not supplied with a sprig of it? Last year some few plants did not blossom, for they were growing in poor soil; they have come through the winter well, and will supply a bouquet for the early Broad Beans (which were planted out in February under the "Red Cross stretcher shelter" described in *Gard. Chron.*, March 2, 1918). The plants began to blossom on April 22, though only about 14 inches high. The conclusion I arrive at is that Summer Savory should be sown in late summer and wintered; it will then be ready for the earlier Beans, without any start in artificial heat. *H. E. D.*

DUTCH BROWN BEANS.

LARGE quantities of Dutch Brown Beans will doubtless be grown during the coming season, both for private use and commercial purposes. We grew this Bean successfully at Aldenham last year, under several conditions. The most satisfactory method was sowing the seeds in boxes during the second week in May, raising the plants in a gentle warmth, and planting them out in a sunny position in well prepared ground at the end of that month, allowing a distance of 2 feet between the rows and 10 inches from plant to plant. This system has much to recommend it over sowing in the open. The seeds germinate better, are much more under control from injury by slugs and late spring frosts, and, in addition, the plants mature earlier and the crop of seed ripens in the best summer weather. When sufficiently ripe, the plants should be pulled up, tied in bunches by the roots, and hung in an airy shed to dry, when the pods may be shelled at convenience and the Beans stored for winter use as required. The growth of the plant is about that of the ordinary French Bean. *F. Beckett.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

ANEMONE PULSATILLA (see pp. 163, 179).—Anemone montana and A. Pulsatilla are quite distinct, even in the wild state, and can be recognised even when not in flower, once you know the true plants. However, it seems that the Anemone Pulsatilla of gardens is more or less a hybrid, having blood of either montana, Halleri or patens, as practically all the species of the Pulsatilla group cross fertilise easily. Your correspondent on p. 163 is quite right with regard to the leaves, but he did not mention the darker colour of the leaves and stems of a violet shade, and the more ferulike appearance. Professor Schinz, in *Flore de la Suisse*, mentions Anemone montana as to be found in the southern Alps, with a white and a pink form near Sion, and Pulsatilla in the northern Alps and the Jura. Thomas, in *Flora von Mittelcuropa* writes in a similar strain. Anemone patens Linn is found near Munich, and is a glorified A. Pulsatilla. Messrs. Regel and Kesselring, Petrograd, distributed a yellow and pink form; they also offer Anemone Pulsatilla chinensis, which is practically identical with A. Pulsatilla Mrs. van der Elst figured in a coloured plate in *Gard. Chron.*, Jan. 25, 1913. A Continental author mentions the following hybrids as occurring in a wild state: A. nemorosa × ranunculoides; A. patens × pratensis; A. patens × vernalis; A. patens × Pulsatilla; A. pratensis × vernalis; A. pratensis × Pulsatilla; A. vernalis × Pulsatilla. None of the American varieties of the Pulsatilla group has flowered here. *E. Riehls, Wood Road, Coleshill.*

FOOD CROPS AND THE PROTECTION OF BIRDS. The serious diminution in the numbers of our resident insect-eating birds, which resulted from the severe winter of 1916-17, and also from the widespread destruction of birds and eggs in the summer of 1917, is a cause for grave anxiety at the present time. Plagues of insect-life of various kinds were reported in the summer and autumn from many districts, and but for the services of summer migrants would have proved alarmingly destructive to Corn, grass, green crops and fruit. This year a greater danger faces us. Under the most favourable conditions it must be some years before many of our small birds regain their normal status. The continual ploughing up of old grassland multiplies insect pests; the increased crops afford them increased food and thus stimulate the hatching out of countless swarms. Owing to these circumstances the protection and preservation of insect-eating birds, and of those birds which destroy small vermin, is a matter of urgent necessity. All who have studied economic ornithology and entomology are agreed that the great majority of wild birds are beneficial to man. *Royal Society for the Protection of Birds.*

TULIPA SAXATILIS (see p. 164).—As my experience with this plant differs entirely from the treatment recommended by Mr. Dykes, I venture to give it. In November, 1908, I planted 12 bulbs in front, but outside of, an open verandah facing south, in ordinary garden soil. The bulbs have never since been disturbed. I had to wait four or five years before I had a bloom, but since then the plants have flowered freely every season, and I have just counted 28 buds, some on the point of opening. Each flowering stem usually bears two flowers, but one of mine has three. *Alfred O. Walker, Ulcombe Place, near Maidstone.*

SCARCITY OF PEAR BLOOM (see pp. 170, 179).—In reference to Mr. Beckett's remarks concerning the absence of blossom on Pear trees, I may say that similar conditions prevail in these gardens. The majority of Pear trees are quite bare of bloom, while other fruits, Plums, Damsons, and Cherries, are a mass of blossom. Even trees of Fondante d'Automne, which have done well consistently for many seasons past, are singularly poor in prospect. Apples show great promise, after bearing heavily last year. All the trees here are young, having been planted by me during the past 10-12 years. *F. W. Spencer, Tockenham Manor Gardens, Swindon, Wiltshire.*

SOCIETIES.

NATIONAL AURICULA AND PRIMULA (Midland Section).

APRIL 26, 27.—Although the nineteenth annual show of Auriculas, held at the Botanical Gardens, Edgbaston, on the above date, was less extensive than in many previous years, and the size and quality of the flowers below the Birmingham standard, the show, on the whole, was a success. Alpine varieties were shown in better condition than the show varieties, which were generally undersized and lacked finish. Of the first-named section, four new varieties gained first-class certificates, against two certificates awarded to show varieties. All the exhibitors were Midland growers, and, with one exception, entries were made in all the thirty-one classes, in two of which there were seventeen entries in each, and in another, fourteen. The weather was fine, and there was a record number of visitors.

Mrs. WINN was the most successful exhibitor; she won the silver medal offered by the Birmingham Botanical and Horticultural Society, the bronze medal of the Society being awarded to Mr. H. W. MILLER. The silver medal offered by Mr. James Udale was won by Mr. E. KENWRIGHT, whilst the two Lindley silver medals for show and Alpine Auriculas were won by Mr. J. T. PLANT and Mr. J. D. WILLIAMS respectively.

The premier flowers were as follows:—Show Auricula George Lightbody, shown by Mrs. WINN (gr. Mr. T. T. Sheppard); seedling show Auricula W. H. Parton, shown by Mr. H. W. MILLER; Alpine Auricula Phyllis Douglas, shown by Mr. J. FREEMAN; Alpine seedling Auricula Tom Stevens, shown by Mr. H. W. MILLER.

First-class certificates were awarded to yellow show Auricula Mary Winn, shown by Mrs. WINN (gr. Mr. T. T. Sheppard); grey-edged show Auricula W. H. Parton, shown by Mr. H. W. MILLER; Alpine Auricula Woodfield Sheppard (light centre), shown by Mrs. WINN (gr. Mr. T. T. Sheppard); Alpine Auricula Kathleen Muir (gold centre), shown by Mr. J. D. WILLIAMS; Alpine Auricula Dora (gold centre), shown by Mr. J. D. WILLIAMS; and Alpine Auricula Tom Stevens (gold centre), shown by Mr. H. W. MILLER.

SHOW AURICULAS.

Mrs. WINN, Selly Park (gr. Mr. T. T. Sheppard) won 1st prizes in classes for (1) eight varieties, (2) six varieties, (3) three selfs, (4) three varieties reserved for local growers, (5) one grey-edged variety, and (6) one self variety.

Mr. H. W. MILLER, Handsworth, was awarded prizes in the two first-named classes. Mr. J. T. PLANT showed the best four varieties, as well as the finest green-edged variety. Mr. RICHARD HOLDING, Bournville, exhibited the best pair of varieties. The same exhibitor also had the best of fourteen entries in a class for one self variety. The best white-edged variety was shown by Mr. J. FREEMAN. The most successful maiden grower was Mr. W. W. FREEMAN.

ALPINE AURICULAS.

The 1st prize in a class for eight varieties, and in another for a single plant possessing a gold centre, were won by Mrs. WINN (gr. Mr. T. T. Sheppard). Mr. H. W. MILLER led in classes for (1) six varieties, (2) one plant having a light centre, and (3) three varieties in a class for local growers. Mr. J. T. PLANT excelled in the class for four varieties, and Mr. J. D. WILLIAMS was successful in a class for a pair of plants. Mr. G. W. ROE took first place among maiden growers, and Mr. E. KENWRIGHT led in a class reserved for young amateur growers.

SEEDLING SHOW VARIETIES.—Mr. H. W. MILLER staged the best pair of plants, his varieties W. H. Parton and Cordelia were very good. The same exhibitor also showed the best grey-edged variety. Mrs. WINN was awarded the 1st prize in a class for one white-edged variety.

SEEDLING ALPINE VARIETIES.—Mr. J. D. WILLIAMS had the leading four varieties. Mr. H. W. MILLER was placed 1st for (1) two varieties, and (2) one gold-centred variety. Mr. RICHARD HOLDING showed the best light-centred variety.

HONORARY EXHIBITS.

A *Silver-gilt Medal* was awarded to the Misses POPE, King's Norton, for Daffodils; a *Silver Medal* to Mrs. WINN, Selly Park (gr. Mr. T. T. Sheppard), for Schizanthus and Antirrhinums and a *Bronze Medal* to Mr. C. S. YEOMANS, Hollywood, for Polyanthuses.

SCOTTISH HORTICULTURAL.

APRIL 2.—The monthly meeting of this Association was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. Robert Fife, President, in the chair.

A lecture on "Allotment Pests" was given by Dr. W. G. SMITH, Edinburgh and East of Scotland College of Agriculture.

An exhibit of *Cineraria Maritima* and seedling Pentstemons was staged by Mr. McHATTIE, Superintendent of the Edinburgh Public Parks.

ANCIENT SOCIETY OF YORK FLORISTS'.

APRIL 20.—On this date the Ancient Society of York Florists, one of the oldest and most interesting societies of the sort, celebrated its 150th anniversary, having been established, according to records still in existence, on April 20, 1768. From that date the Society has been carried on without a break by succeeding generations of enthusiastic florists, and it is one of the oldest floricultural societies in the country.

The first show of the Society was held a week from the date of its inauguration on April 27, 1768. The prizes, apart from the cups and silver spoons and goblets, included pieces of plate, value 5s. 6d. each, and in 1770 Gooseberries were first shown, prizes being given for the exhibit with the best number of berries to the pound and also for the largest berry. The Gooseberry Show was discontinued in 1833. In 1856 Polygoneums were shown for the first time, and in 1859 Dahlias were admitted, the shows gradually being thrown open to the exhibition of practically all classes of flowers.

LAW NOTE.

DAMAGE TO A MARKET GARDEN BY SUBSIDENCE.

In the Outer Division of the Scottish Court of Session judgment has been given in an action brought by Mr. Thomas C. Gibson, market gardener, West Thorn, London Road, near Glasgow, against Mr. A. J. Crawford, Earle, Lanarkshire, and the Earnie Coal Company, for payment of £2,600 as damages caused by coal workings under his market garden, and also for interdict against the defenders working coal and other minerals there. Lord Ormidale gave decree against the defenders for £1,200, with expenses, but, as the action for interdict was not insisted upon, dismissed that part.

CROPS AND STOCK ON THE HOME FARM.

SUCCESSION OF CROPS.

Following a crop of late Turnips eaten off by sheep in March it is usual to sow Oats or Barley. Where, however, the root crop was poor owing to such influences as late sowing, poorness of soil, or the Turnip plants being infested with Charlock to such an extent as to cripple their growth, it would not be wise to sow corn. In such cases adopt one of the following methods:—Summer fallow, clean the ground of Couch if present, apply farmyard manure in September, plough, press if light soil and sow with Wheat. An alternative method would be to plough and clean the land and sow Mustard broadcast in July, at the rate of 20 lbs. per acre. Plough in the crop early in October and sow with Wheat. This latter is a good plan to adopt where sheep are not kept to require the Turnips. A crop of Mustard is one of the best methods of preparing land for Wheat. Two pounds of Rape drilled with 1 lb. of Pomeranian White Turnip is ample seed. Some broadcast the seed as being easier, but I do not approve of this method, especially in soil which is liable to Charlock growth, as no means exist by which the Charlock plant can be removed. When, however, the seed is drilled, horse-hoeing is easy, and the stirring of the surface soil accelerates the growth of the Rape and Turnips. If the plant does not start into growth vigorously, sow 2 cwt. of sulphate of ammonia per acre evenly over the crop.

WEEDING THE CORN CROPS.

The eradication of weeds in Corn is, I hear, much neglected, but it is not wise to allow Docks or Thistles, for example, to remain, as they are detrimental to the sale of the straw. Some persons cut off the crown of Docks with a weed hook, but this produces treble crowns and naturally more seed. A two-pronged prong is the best tool with which to root them up, and when found they are brushed with. Thistles should be cut off with weed hooks; cutting the plants down weakens their growth and prevents their seeding. Scabious is a bad weed among Corn, and it increases rapidly.

SWEDES.

This root crop is important to the cowkeeper and sheep farmer. For the former, Swedes in October following Turnips in August and September form a valuable food, increasing the milk yield considerably. For fattening cattle the Swede Turnip is the most valuable of all roots, whilst to the sheep farmer with ewes and lambs in March, April and May, a full Swede crop is a boon. For a flock of 100 ewes and as many lamb I always try to have at least thirty acres of Swedes.

If the land has previously carried a straw crop, is free from weeds, and was autumn ploughed, 1 cwt. of superphosphate, 30 per cent. strength, will grow a full crop of Swedes. In southern counties Swedes suffer much from mildew if the seed is sown before the middle of June and a spell of dry weather sets in in July. It is not wise either, to follow Turnips with Swedes. I have seen much rotting of the roots of the latter before Christmas when sown after a Turnip crop.

Ploughing the land repeatedly before sowing the seed is important. In dry weather it is a good plan to sow the same day as ploughing is done; the soil then is more uniformly moist, ensuring a quick germination, which is all important, as the Swede plant should make free, quick growth from the start. When the soil is ploughed, left a day or two, then harrowed, rolled, and so forth, the surface becomes devoid of moisture, and as the seed is not drilled more than an inch or so deep, germination is slow until rain falls, which may not be for weeks, and thus the plant is retarded at the most critical period.

Directly the plants in the drills can be seen across the field, stirring the soil about the plants with the horse hoe, or even harrows drawn crosswise over the rows before thinning, will hasten growth. Two lbs. of seed per acre is ample, and 1 lb. of Rape seed. This I sow through one coulter of a five coulter drill. I find the lambs appreciate the extra green food this row of all Rape provides in the spring. The varieties of Swedes are numerous: Dunn's Defiance, Toogood's Purple Top, John Bull, and White Elephant are desirable sorts. *E. Molyneux.*

MANGOLDS FOR SEED.

In view of a possible shortage of mangold seed next year, the Food Production Department suggest that farmers having a surplus of mangolds at the present time should consider the desirability of planting selected roots for seed production. Sound, medium sized, well shaped roots should be selected, untouched by the trimming knife. The ground should be prepared by deep tillage and liberal manuring, and the roots planted at least 2 feet apart; if planted at a greater distance they suffer from beating by the wind. All roots planted should be sunk in the soil to their full depth, so that the crown shows just above the surface. The seed is usually ready for harvesting in September, and may be threshed out by flail on a sheet or on the barn floor. A yield of about 3 lb. per rod (30½ square yards) may be expected under favourable conditions.

Smilax, per bun. of 6 trails ...	4 0– 4 6	

REMARKS. All white flowers are very scarce. Much prices are maintained for Lilium longiflorum and Richardias (Arums). The supplies of Carnations are sufficient for the demand, and the quality is generally good throughout. The cold weather is preventing an excessive supply of Roses, and prices are still high for the best blooms. Daffodils are also dearer, and prices advanced from 2s. to 4s. per dozen bunches during Friday and Saturday last. The better quality flowers now consist of Gardenias, Lapagerias, Stephanotis, and white and coloured Sweet Peas. Cattleyas are the leading line in Orchids. Spanish Irises are arriving in good condition, and prices are a little easier. Small consignments from the Channel Islands are arriving here on Mondays, Wednesdays, and Thursdays only. The chief kinds of Narcissi just now are Barri, Tulips, and Ixias. French flowers are fine in quality, and in quite satisfactory condition when they arrive.

REMARKS. Supplies of English Apples are practically cleared. A few samples of French Russets are on offer ahead. A few samples of French Russets are on offer ahead. A few samples of English Black Hamburgh and Muscat Grapes are available. Supplies are increasing daily of home-grown Cucumbers. Good Tops from Worthing are on offer, and Melons are making their appearance. English and Channel Islands Tomatos are in ample supply. The following forced vegetables are also plentiful. The following forced vegetables are also plentiful: Asparagus, Mushrooms, Seakale, French Beans, Cucumbers, New Potatos, Mushrooms and Peas. Outdoor Seakale and Asparagus are also on offer. Supplies of Greenkale and Asparagus are also on offer. Supplies of Greenkale and Asparagus are also on offer. *Supplied by Messrs. Rigg & Co., Covent Garden Market, May 1, 1918.*

Obituary.

MR. WILLIAM MELVILLE.—We regret to record the death, on April 17, of Mr. William Melville, formerly gardener at Glenlee, New Galloway, Kirkcudbrightshire, who retired several years ago. Mr. Melville, who was in his 83rd year, died at Portalloch Gardens, Argyll.

J. C. WATT. We regret to announce the death, on the 15th ult., of Mr. J. C. Watt, head gardener, Central Queen Street Gardens, Edinburgh. Mr. Watt, who was seventy years of age, had occupied his position for 37 years, and was on duty the day before his death.

ALEXANDER MILNE. The death is announced, at the Edinburgh Royal Infirmary, of Mr. Alexander Milne, gardener to Lord Lamington, at Lamington House, Lamington, Lanarkshire. Mr. Milne was 67 years of age.

WILLIAM MERRILES. We learn with regret of the death of Mr. William Merriles, Edinburgh, a prominent member of the Scottish seed trade. He served his apprenticeship with Messrs. Roughhead and Park, Ltd., seedsmen, Haddington, and was associated with the firm for upwards of 50 years, in the capacity of one of the directors during the past ten years.

JOHN G. BARKER. Our contemporary, *Horticulture*, U.S.A., states that Mr. John G. Barker, Superintendent of Rosedale Cemetery, South Bend, Indiana, died on February 7, after a brief illness, at the age of 75 years. Mr. Barker was a native of Huntingfield, Suffolk, England. At the age of 14 he went to the States with his parents, and assisted his father, who became superintendent of Forest Hill Cemetery, Utica, N.Y.

LAWRENCE COTTER.—Mr. Lawrence Cotter, manager of the Lakeview Rose Gardens, Jamestown, N.Y., died on Saturday, March 23, after a long and painful illness. He was a native of County Cork, Ireland, and emigrated to America when a young man, since which time he has been active and prominent in commercial horticulture in America.

MAURICE DE VILMORIN. As these pages are being passed for press, news reaches us of the death of Monsieur Maurice de Vilmorin, one of the partners of Messrs. Vilmorin, Andrieux et Cie., nurserymen, Paris. He died at the end of last month, at the age of 69, and was buried in Paris on the 29th ult.

ANSWERS TO CORRESPONDENTS.

APPLE BUDS INJURED: *G. F. M.* The flower-buds have been attacked by grubs, and the birds were probably seeking them. Spray the trees with arsenate of lead either before or after the blossoms open. The specific will kill the grubs and render the buds distasteful to the tits which you consider may have caused the damage.

APPLE DISCOLOURED: *Pomona.* There is no fungus or organism of any kind on the Apple which would account for the markings, which must have been caused by some external agency, such as hail.

BEANS DISEASED: *M. M.* The Beans are infected with the fungus known as Uromyces Fabae, or Bean rust. Spraying with dilute Bordeaux mixture arrests the spread of the disease, but cannot be said to constitute a cure, which has yet to be discovered. Burn all the infected plants as soon as the Beans are harvested.

BULBS DISEASED: *A. O. W.* Both plants are attacked by the fungus Botrytis. This fungus is usually a saprophyte, but when plants are subjected to unfavourable conditions (of weather, etc.) it becomes parasitic. Remove all diseased parts of the plants and apply flowers of sulphur.

FUNGUS ON LAWN: *F. O. L.* The fungus is apparently a species of Peziza or allied genus. It would not be advisable to eat it before having its identity determined more exactly.

GRUBS ATTACKING PEAS AND CABBAGES: *M. L.* The Peas are attacked by Blanjulus guttulatus—the small snake millipede. The insects are not likely to do more harm if the plants are stimulated by a fertiliser and a dressing of equal parts fine lime and old soot is hoed in each side of the rows. The millipedes from the land on which the Cabbages are planted are Julus londinensis; they are not harmful.

NAMES OF PLANTS: *H. H. T.* We do not undertake to name varieties of Pelargoniums or other florists' flowers. Send them to a nurseryman who specialises in Pelargoniums. *J. B. M.* Skimmia japonica (male plant).

NECTARINE AND PEACH LEAVES: *Leaves.* See reply to *Puzzled* and *H. P.*

PINE DISEASED: *W. A.* The fungus on the Pinus is the "rust" (Coleosporium Senecionis). It is also found on species of Senecio (S. vulgaris, or Groundsel, and S. Jacobaea, Ragwort). Such weeds should not be allowed to grow in or near the nursery.

ROSE CANKERED: *J. H.* The Roses may have been injured by the fungus Coniothyrium, but only a barren stroma of the fungus was present; it is therefore not possible to determine the exact identity. Cut out and burn the cankered parts of the branches.

VEGETABLES AS PAID WORK: *Learner.* As you contracted to supply "House, coal, and vegetables," without mentioning that your offer only applied to vegetables grown on the estate, we consider that you are bound to supply them, even if it involves buying them for that purpose. If you could prove that there exists a general custom to the effect that gardeners were entitled, as perquisites, to a reasonable quantity of vegetables grown on the estate, you might possibly have contended that your offer had only reference to this custom; but even then the burden of proof would have been upon you.

VINE LEAVES INJURED: *Puzzled* and *H. P.* The leaves are not infected with any specific disease; their injury has followed improper conditions of cultivation. As a rule, such a condition is produced by imperfect ventilation of the vinery. Early in the day there is generally an excess of moisture in the atmosphere, and when this condenses on the leaves bursts of bright sunshine are apt to cause "scalding" of the foliage.

THE MARKET FRUIT GARDEN.

APRIL for the most part was a cold and cheerless month. The wind was from the north, north-east, or north-west on most days, and on rare half it was very strong. Only three times, however, was frost registered on the screen at my place, and then it did not exceed 2° in the upper parts of my orchards or at the lowest level. In some parts of the country, including some important fruit districts, 8° were reported as having been registered on the 13th or 19th, doing some harm to Plum blossom. Rain fell at my station on 16 days or nights, amounting to 2·53 inches. The progress of vegetation was extremely slow during the month, in consequence of the general lowness of the temperature, the nights having been very cold, even after the few sunny days.

Fruit Prospects.

Apart from damage by frost, which is reported to have affected Gooseberries as well as Plums, we can only judge as to probable fruit crops by the extent of blossoming. This is generally fair with respect to Plums, Gooseberries, Currants, and Cherries, which it seems likely to be so with Strawberries. In my orchards the only variety of Plum which has not made a fair to full show of blossom is Belle de Louvain. This variety is now in the seventh season from the planting, and it has not yet shown any blossom worth notice, less than a score of the trees having had any at all. Such shyness in fruiting is greatly to the disadvantage of the variety, which it was hoped might be to a great extent a substitute for Victoria, now that the latter has become so seriously liable to silver-leaf attack. But although frost in my district was not severe enough to do any material damage to Plum blossom, the very cold and often virulent winds of April were not conducive to its free setting. It was only occasionally that bees and other insects were at their useful work of pollinating. Reports as to Pear blossoming are almost uniformly unfavourable, although the comparatively small number of trees grown by me have enough bloom on the whole for a full crop. The outlook for Apples is a chequered one; some varieties are fully furnished with trusses of blossom buds, only a few of which are open at the time of writing, while others are almost entirely bare. A surprising proportion of fruit buds, on opening, were found to be only clusters of leaves. They were fruit buds, but not sufficiently developed to blossom this season. Even where there is a great show of blossom, however, there is grave reason to fear disappointing results, unless timely spraying has averted a danger to be noticed below.

Another Caterpillar Season.

When my notes for March were written caterpillars had only begun to hatch to a small extent. Early in April, however, they became numerous on nearly all varieties of Apples, and the attack developed into one as bad as that of last season. But there is this important difference in the circumstances of the two seasons in relation to this pest. In 1917 I was not prepared for so destructive an attack of caterpillars, never having seriously approach to it before. This year I was on the watch for it, spending most of my time examining trusses of blossom-buds with a lens, and promptly beginning my counter-attack as soon as required. All varieties infested to any considerable extent were sprayed with soft soap and either arsenate of lead or nicotine at 90-40 degrees of purity, the quantities used with 100 gallons of water being 10 lb. of soap, 4 lb. of arsenate of lead, and 2 lb. of nicotine. As nicotine costs 14s. 6d. per lb. its use is extremely expensive, consequently, it was used to a much smaller extent than arsenate of lead. Soft soap was used with nicotine because of its penetrative capacity, while it was used with arsenate of lead as a contact spray fluid to kill aphides, suckers, and small caterpillars. Aphis was not found to any considerable extent on any variety except Apples other than Worcester Pearmain and Allington Pippin, but suckers were numerous on several varieties [illegible] Apples and Pears. The spray [illegible] was done early. Previously I have waited [illegible] the blossom-buds to open separately, but this season I gave them [illegible] caterpillars and other pests before they had time to do much damage. To some extent the work was done too soon, while the trusses of buds were so compact that the spray could not get into them properly, so that the trees had to be sprayed a second time. The results were fairly successful, but there are to be noted [illegible] subsequent examination having shown that all but very small proportion of the caterpillars had been killed.

In the last week of April a bad infestation of caterpillars on Plums and particularly on espalier trees was discovered, with slight attacks of the aphis in places. These are to be dealt with after all the blossom had fallen, which is not the case at the time of writing.

A General Caterpillar Campaign Needed.

What is wanted is a general effort among fruit growers this season to destroy caterpillars, not only for the purpose of saving serious loss in this year's fruit crops, but also and even more emphatically, with the object of preventing the production of myriads of the pests in the next and later seasons. In districts where fruit farms are numerous and adjacent, the latter object is certain to be attained by the action of a minority of fruit growers, as the moths which produce the caterpillars are strong flyers, and clean orchards are infested from foul ones. It is particularly unfortunate that bloom for spraying should be short, and that spray stuffs should be inordinately expensive. But there is no other work at this time which should not be set aside, if necessary, for the sake of spraying, and no outlay that can be expected to prove more remunerative than that which is necessary for fighting against the destroyers of fruit and foliage and the prospective progenitors of similar malefactors for action in future seasons.

How to Destroy Apple Suckers.

For the first time my spraying operations have been fully successful in the destruction of Apple suckers, the reason being that the insects were attacked when they were quite small, and before they had become old enough to protect themselves with globules of mucus and the filaments which they also excrete. This is not to say that they have been exhaustively destroyed. But in many cases forty to fifty trusses of blossom buds on varieties that had been badly infested have been recently examined by myself and another observer without finding a live sucker, hosts of dead ones being found by the use of a lens. This was where the trees were drenched in spraying until they dripped all over. It has been a difficulty to induce my sprayers to spray profusely enough, and where they were left too much to themselves a second spraying in some cases was found necessary. Most writers on spraying urge that when either nicotine or arsenate of lead is used the spraying should be a slight and misty one. Where this plan was adopted, though too much hurrying over the work, a second spraying was found necessary; but where the trees were drenched, one operation was strikingly successful. It is expensive to drench trees with costly spray fluids, no doubt, but a doubled expense pays well when it secures success, instead of partial failure. Even the poison needs to be forced among the buds partially separated blossom buds in the trusses, in order to poison the caterpillars before they have spoilt all or many of the buds, while it is obvious that the soft soap or nicotine cannot otherwise destroy suckers or aphides.

Nicotine versus Arsenate of Lead.

With respect to the comparative advantages of these two spray-stuffs, it is desirable to make further observations before coming to a decided conclusion. At present I am disposed to prefer nicotine, with soft soap, for early spraying, and arsenate of lead, also with soft soap, for later work. There is no doubt that nicotine adds greatly to the strength of soft soap as a contact wash for killing suckers, aphides, and small caterpillars; but, as a poison for biting pests it is less effective than arsenate of lead, and less lasting in potency. Therefore the latter is much more likely than the former to destroy caterpillars hatched after a spraying, as well as those which have escaped from the blossom trusses to the foliage. After the present date the preference, it seems to me, should be given decidedly to arsenate of lead.

Disappearance of Thrips.

In previous years it has been noticed most dentally that thrips have almost entirely disappeared from the trusses of Apple blossom buds shortly after a spraying. This season the subject has had more definite attention in connection with the worst infestation of the insect that I have ever seen. Over 200 trees of James Grieve variety at the beginning of April were so densely attacked by thrips that hardly a truss was free from them, and four to six in a truss were frequently counted. The trees were sprayed with soft soap and arsenate of lead on April 5, and a few days later it was found that some thrips were dead in the trusses, while many more were missing. On April 15 only 19 were found alive in 40 trusses, and on the 25th only two in 60 trusses. If any entomologist who may read these notes can account for this wholesale disappearance the explanation would be interesting. Mr. Theobald states that the insects of the first brood normally drop to the ground not long after they have reached maturity, and that some which he had under observation had all dropped by May 10. But on April 25 the pests, or at least many of them, were not mature, and the majority of them had disappeared fully a fortnight before that date. My suggestion is that, when hit by the spray, many of the insects drop to the ground, and that, later, others that have been wetted and weakened rather than killed, drop or are blown from the trees. Otherwise it is possible that the embryo fruit and foliage are rendered distasteful to them by the spray fluid, and that they drop to the ground prematurely to pupate and to produce a second brood of egg-laying insects by about the middle of June. *Southern Grower.*

PLANT NOTES.

NICOTIANA SYLVESTRIS.

The two tobacco-yielding species of Nicotiana are N. Tabacum and N. rustica, both South American plants, now largely cultivated in the warmer countries of the world, and in some of them established as wild plants. According to De Candolle, all the fifty or so species that have been described by botanists are American except N. suaveolens, of Australia, and N. fragrans, of the Isle of Pines, south of New Caledonia. The same authority states that certain narcotic plants were smoked in the Old World from a very early epoch, and that tobacco was only substituted after the discovery of America. Although the leaves of only two species of Nicotiana are used for the making of tobacco, there does not appear to be any good reason why other species should not possess the same property, except, perhaps, that the two named are easy to cultivate, and smokers are quite satisfied with the qualities of the best samples of the "weed" obtained from them.

N. suaveolens and N. fragrans have attained considerable repute as garden plants on account of the delicious fragrance of their large, long-tubed flowers. The red-flowered N. Forgetiana, introduced from S. Brazil by Messrs. Sander and Sons eighteen years ago, was crossed by them with other species, and the beautiful hybrid tobaccos distributed under the name of N. Sanderae were the result. So far as I know Messrs. Sander did not use N. sylvestris in their crossings, but in my opinion it is a better plant for the purpose than any other of the Nicotianas. It is a tall, stout, branching, leafy annual 5 or 6 feet high, with lyrate, dark green leaves a foot or more long, and large nodding cymes of white, long-tubed flowers. The plant first flowered at Kew in August, 1898, the seeds having been obtained from Messrs. Dammann and Co., Naples, who procured it from the mountains of Bolivia at an elevation of about 5,000 feet. For years a bed of it was annually a striking feature at Kew, as shown in the photograph reproduced in fig. 84, which was taken in November when the plants were in perfect health and in full flower. Seeds were sown under glass in spring, and the young plants were put in the bed in early summer. They produce seeds in abundance. The plant is an annual, as nearly all the Nicotianas are. Another large-leaved species is N. tomentosa (colloseal, from Peru, which in a greenhouse at Kew reached a height of 10 feet and had leaves a yard long and 18 inches wide; the flowers were in large terminal panicles and were bell-shaped, yellowish, flushed with rose. This species has also been used effectively as a sub-tropical bedding plant at Kew. W. W.

ORCHID NOTES AND GLEANINGS.

LAELIO-CATTLEYAS AT THE DELL, ENGLEFIELD GREEN.

In Baron Schroder's famous gardens there is a remarkably fine display of Laelio-Cattleyas. The large, span-roofed house, in three divisions, contains over 3000 blooms. The greatest number of flowers are borne by fine specimens of L.-C. Fascinator (C. Schroderae × L. purpurata), which bears fine spikes, on each of which are from three to six flowers, varying in tint from blush-white with rosy-mauve, veined lip, to bright rose with ruby-red labellum. The Dell strain of L.-C. Aphrodite (C. Mendelii × L. purpurata) is exceptionally fine. Among yellow-petalled varieties L.-C. Anaconda, golden-yellow with claret-coloured lip, is specially attractive. In the general collection there is a fine specimen of Cattleya Skinneri alba, bearing many flowers; a batch of the white C. Astor, and other white Cattleyas; a handsome batch of Brasso-Cattleyas and Sophro-Cattleyas, including some very promising new forms; and a selection of the best Miltonias, including the unique M. The Baron and M. Vexillaria Memoria G. D. Owen. This latter was one of the original specimens of the old collection.

ORCHIDS FROM WARNHAM COURT.

C. J. Lucas, Esq., sends flowers from plants flowering in his collection at Warnham Court, Horsham.

Odontoglossum Crispo-Othello (raised between O. crispum and O. Othello (Adrianae × Harryanum) is a pretty and distinct flower, and throws an interesting light on the possibilities of development by the hybridiser. The outstanding features in the flower are the thick substance imparted by O. Harryanum, and the unexpected development of the lip, which is broad, flat, and nearly circular in outline. It is attributable to O. Adrianae, which has much undulation of the margin of the lip. The wavy edge has been ex-

panded, and membrane provided for its extension in a flat surface, the margin only having a very thin, wavy band, which is fimbriated. The flower is of good shape, cream-white, with purple spots of varying sizes.

ODONTOGLOSSUM DIRCIMIUM (Dirce × eximium Warnham Court variety) has bright red-dish-claret coloured sepals and petals, the tips and slight margin in the outer halves being white, tinged with rose.

O. ZENA (Harryanum × sceptrum) is a great improvement on O. sceptrum, and has a large, sulphur yellow, fringed lip.

O. ANDERSONIANUM STUNNER forms a link with the old-time imported natural hybrids, and is one of the best varieties.

LAELIO-CATTLEYA GEORGE BRANCH (Schilleyensis × G. S. Ball) and two very dissimilar flowers of L.-C. Lawrie (C. Lawrenceana × L.-C. warnhamensis) are included. Both these flowers show C. Lawrenceana plainly in the lip, the colour of one being ruby red and the other purplish mauve with orange-coloured disc.

habit. Such dimorphism is, if I remember aright, described by Darwin in his *Forms of Flowers* as occurring not infrequently in thrum and pin-eyed species. On my hypothesis—if a guess may be dignified by so large a term—the pure pin and the hybrid between pin and thrum have of necessity the large habit, and only in the pure thrum may the compactness and floriferousness find expression. If this is so then it is desirable not to let the two forms have intercourse with one another, for if they grow side by side any chance seedlings are almost or quite sure to be hybrids, and to have the less pleasing habit.

The pigs are now established, and in the absence of birds who seem, except a robin which comes and perches almost on my spade to collect the wire-worms to have deserted my nesting-boxes, make a pleasant porky music near the house. I have been testing their taste in weeds and so far find that Chickweed is the favourite. Next they take to oil, yeasty when it is in blossom, and after that a patty, smooth my light-turned

deuer and myself. As he remarked but yesterday, "to see this place now anyone would say that we *mother* of us knew anything about gardening"; truly a subtle way of setting a novice in his place. *A. N.*

THE ALPINE GARDEN.

SEDUM COERULEUM

THE Blue Stonecrop, Sedum coeruleum, is of very suitable stature for the Alpine garden, generally about 6 inches or less, while the pale blue flowers do not clash, but rather harmonise, with other rock plants. It may be employed profitably to give a display of blooms after the bulk of the perennials have gone to rest. Sow the seed very thinly where the plants are required to bloom, in a sunny position in light soil, from the middle of April until the end of May. Thin the seedlings to about 3 inches apart.

CONFESSIONS OF A NOVICE.

INEXTRICABLE links associates the early year note of the cuckoo with spring, were it not so my garden in its present immobility would deny that the life of the earth is again renewing itself. It is true that the land is green again, and that the pink and white blossom of the Apricot is breaking; but, despite those inevitable movements of life, these things that stir in spite of untowardness of the weather, the garden as a whole is doing its best to "stand still." The Birches have recorded their protest against the nipping winds by the jaundiced sodden of their young complexions. Anemone Pulsatilla, or mayflower, I know not which has produced none but the miffiest of flowers, and flowers of the Magnolias, of which last year I wrote with pride, have become lax brown flatterns instead of white emblems of the year's dawn. Only the Saxifragas seem indifferent to the east wind, and flower as though it reminded them of the cool breath of the snows. Old men tell me that we must search the records for nearly forty years before we find a parallel with this year's unkindly coming in of summer.

The general scarcity of Pear blossom has been referred to by Mr. Beckett and other of your correspondents. Here in this garden is a pretty illustration of the fact that this scarcity is to be regarded as the inevitable aftermath of two years' plenty. On all save two trees the blossom was of the slightest, but two Doyenne du Comice bloomed profusely. They were young cordons, bought and planted rather late last year, when they bore no flowers. Wherefore I infer that the popular explanation is the correct one, and that profuseness of blossoming and fruiting bring barrenness in their train.

Like an oasis in a desert of dreary days Saturday of last week stands out, and, as good fortune willed it, I happened on that day to make a spring pilgrimage to Wisley. There, as always, I found much to admire and something to puzzle about. This time the puzzle was Primula Juliae. There, on the rock garden, this charming plant is flourishing, and in two forms. The one plant is small, both as to leaf and flower, of compact habit, and admirable as a garden subject. The other is of larger and laxer habit, much less of a cushion plant, with individual flowers undoubtedly superior to those of the former, but so few in numbers as to make a relatively poor showing. A study of the specimens indicates that whereas the small, compact form is thrum-eyed, the larger form may be pin or thrum. I think that the explanation is to be found in the direction of what the botanists call dimorphism; that the thrum habit goes with floriferousness and compactness, and the pin habit with sparseness of flowers and laxity of

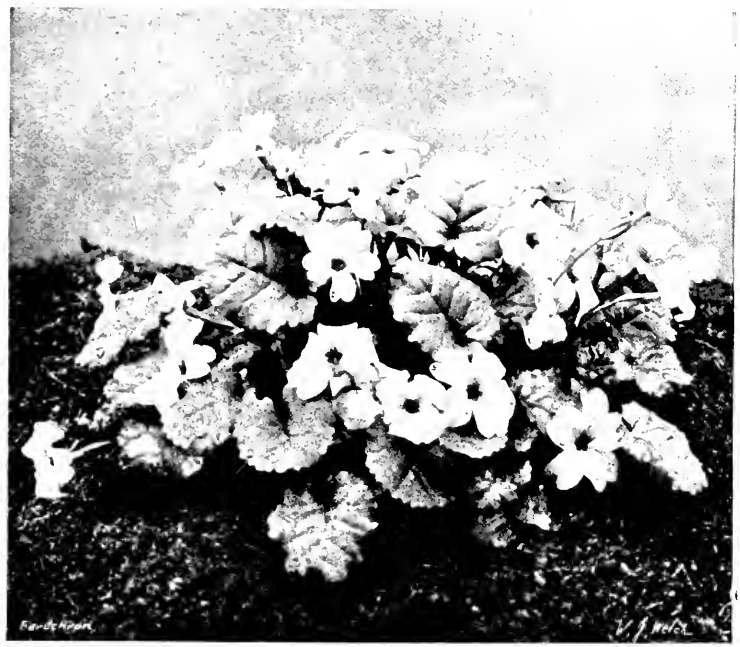

FIG. 85.—PRIMULA JULIAE: FLOWERS ROSY PURPLE.

borders enough Sorrel grows to feed a herd of asses. I do not recall that any of the books that discourse of weeds have pronounced praises on the subtleness of Sorrel in its habit of growth. Yet the weed deserves praise, such as one gives reluctantly to successful enemies. Not only does it grow indefinitely, budding at short intervals—pushing out laterally or plunging vertically downward, but, and this is its chief anchor, which makes dislodgment so difficult, each runner grows for a foot or so and then bifurcates. The two branches turn their backs on one another, and go off in opposite directions, with the result that when the main branch is torn out only one of the laterals comes away with it, the other remaining to cumber the ground and teach patience to the gardener. But in any case weeds in a garden now are an honourable sign, and I feel no jealousy but only pity for those of my neighbours whose borders are spick and span; yet I will confess here that the weed-grown gravel paths, though they feed my patriotic pride, are a source of real sorrow to my gar-

PRIMULA JULIAE.

THERE are some flower-lovers who do not care for the colour of Primula Juliae (see fig. 85), and consider it hard and unsatisfying, yet, grown in suitable surroundings, such as in the chips of the wet moraine or in short grass, the plant is quite attractive.

It is one of the dwarfer hardy Primulas classed with our common Primrose, but very distinct. The small rounded leaves make a low carpet on which nestle a wealth of little red flowers. The red is undoubtedly a trifle hard, but, all the same, the flower is a precious one. It is well to mention, however that there are forms of P. Juliae which are not so floriferous as others, and that it is desirable in purchasing to stipulate that the free-flowering variety should be supplied. Although a moisture-lover, and delighting in damp places, I have found it grow and flower highly satisfactorily in a dry moraine. The species is a native of the Caucasus. *W. Arnott.*

NOTICES OF BOOKS.

FUNGOID AND INSECT PESTS AND THEIR CONTROL.*

THIS pamphlet, published by the author, should be in the hands of all gardeners who desire to know something of the common garden pests. The plan of the pamphlet is to describe by coloured illustrations the chief phases in the life history of each of a number of common pests, to attach to the illustrations a brief account of the pest, of the injury which it does to the plant, and of the method of control.

Although it cannot be said that the illustrations are always well done—that of club-root, for example, we ourselves, though only too familiar with the symptoms of the disease, find a difficulty in recognising—yet their boldness and distinctness make them in general valuable as means of identification. Among the pests and diseases illustrated and described are Bean aphis, club-root, Cabbage white butterfly, Cabbage moth, Cabbage-root fly, Cabbage-gall weevil (which should be placed next to the page devoted to club-root, for the symptomatic swellings on the root caused by the weevil are often mistaken by the uninitiated for the more irregular lumps caused by the club-root parasite), Carrot fly, Celery spot and "blight," Celery fly, Onion mildew, Onion fly, powdery mildew of Peas and Pea spot (the allied disease of Haricot Beans might also be mentioned), Potato blight, brown scab, black wart, and corky scab.

The methods of control are in most cases well chosen, but we note the tendency common in those who approach the subject from the pathological point of view to prescribe a remedy at all costs. For example, we ourselves should never waste time or money in spraying Peas affected with powdery mildew with Bordeaux mixture. This disease is general in late summer among Peas grown on light soil, and may be regarded as an indication that the soil is unsuited for the purpose of growing late Peas. We prefer, therefore, to cut our losses and either refrain from growing late Peas at all, or choose a variety which is fairly resistant to mildew and let the disease do its worst.

In the account of the Cabbage-root fly the early symptoms—flagging of the plants in sunshine and a general yellowing of the foliage—should be mentioned, for plants which are thus affected should be pulled up at once, the maggots in the roots destroyed, and the space the plants occupied used for some crop other than Brassicas.

Other comments of a similar nature might be made, all tending to show that this booklet leaves room for improvement, but, when all is said, the fact remains that it is in the main an excellent piece of work and one which deserves to be generally known among and consulted by gardeners. We hope, for the sake of small cultivators generally, that Mr. Mosley will regard this pamphlet as a first edition, that he will continue his observations on these pests, and as his experience is enlarged will give the public the benefit of it in a new edition. There is also a great body of scattered information—much of real value—which is to be gleaned from the literature relating to horticulture and to garden pests, and it would be a really useful work if the author would survey this, test his information by actual experiments and give the public the benefit of the results. As an example, it is stated somewhere in the French periodicals that copper-sulphate is peculiarly fatal to slugs: if this be true, and a device for applying it could be discovered, many a gardener would rise up and call the discoverers blessed. The booklet concludes with illustrated accounts of the general feeders—wire-worm, snails, slugs, millipedes and centipedes. Under the heading of wire-worms attention should be drawn to the beneficial effect of a dressing of sulphate of ammonia in enabling the crop—for example, Potatos—to "grow away" from the pest, and also, in the case of Tomatos, to the successful practice of shallow planting so as to leave the ball of the root and not the stem at the mercy of the pest. Again, it would be interesting to know the evidence on which it is stated that Mustard is a good crop to take on ground infested with wire-worm. We ourselves have tried it, but not under critical conditions. Mention should also be made of the value of naphthalene and of the proprietary specifics which in certain conditions give good results.

Finally, we suggest that the plant pathologists interested in horticultural crops should arrange between them a programme whereby each undertakes to study thoroughly and continuously one or more of the chief pests and to go on doing so until he is satisfied that he has the pests really under control. Five years expended thus would do more for horticulture than a generation of exhortation and incompletely authoritative advice addressed by pathologists to practical gardeners.

The Week's Work.

THE KITCHEN GARDEN.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

BRUSSELS SPROUTS.—The earliest plants of Brussels Sprouts are ready for transplanting in their permanent quarters. Allow a distance of 2½ feet between the plants and the same space between the rows. Lift the roots carefully with a trowel with a good ball of earth attached to prevent a check to growth. Although Brussels Sprouts will grow on almost any kind of soil, only ground that has been thoroughly prepared during the winter will give good results. Transplant seedlings of later-sown plants at 4 inches apart in a sheltered position. Syringe and shade the seedlings if necessary for a few days, and do not allow the roots to suffer for want of water.

LEEKS. Leeks raised from seed sown as advised on p. 34 to produce large specimens should be ready for planting in narrow trenches prepared as for Celery. Fork in a liberal quantity of rotten manure in the bottom of the trench, and cover with the finest soil to the depth of 4 to 6 inches. Plant carefully with a garden trowel, allowing a space of 1 foot apart for single rows. Give the roots liberal supplies of liquid manure throughout the growing season. To economise labour and ground Leeks large enough for all ordinary purposes may be obtained by sowing seed out-of-doors in March and planting the seedlings in deeply-dug ground at a space of 1 foot and 15 to 18 inches between the rows. Make a deep hole with a dibber and drop the plants in the hole, just covering the roots with fine soil.

BROAD BEANS.—Sow one or two more rows of Broad Beans of a maincrop variety in double lines 2½ feet apart for autumn supplies. A row of Spinach may be intercropped between the Beans, and the Spinach will be used before the Beans need the space.

POTATOS.—Finish the planting of maincrop Potatos at the earliest opportunity. Encourage the development of plants which are well through the ground by frequently stirring the soil. Ventilate Potatos in pits and frames freely, removing the lights altogether on mild and rainy days, and keep them well supplied with water.

GENERAL REMARKS.—Many seedlings raised on gentle hot-beds and in cold frames require transplanting in a sheltered position 3 or 4 inches apart. Examine seed-beds carefully and make fresh sowings where there are failures. Make small sowings weekly of Mustard and Cress in slightly shaded positions. Also make regular sowings of Radishes; sow and prick out Lettuce regularly, utilising frames that have been cleared of other subjects, so that supplies may always be available. Make a sowing of Endive now, and further small sowings about once a fortnight for autumn and winter supplies. Thin seedling Turnips, Onions, Carrots, and similar crops at an early stage. Run the Dutch hoe between the rows as soon as the plants are well through the ground to prevent the growth of weeds, and keep the soil in a friable condition.

THE ORCHID HOUSES.

By J. COLLIER, Gardener to Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate.

ODONTOGLOSSUM.—Plants of Odontoglossum Insleayi and its variety Leopardinum are starting to grow afresh, and should be repotted or top-dressed as is found necessary. Those that have sufficient pot-room for another year, and with compost in good condition, should be immersed in water in order to soak the soil thoroughly, afterwards allowing it to become partially dry, when portions of the old materials should be picked from between the roots on the surface of the pots, and replaced by fresh compost. Others that need repotting should be afforded sufficient rooting space to accommodate them for two seasons. Ordinary flower-pots form the most suitable receptacles. O. Uro-Skinneri is also developing new roots from the base of the young shoots, and should be treated in a similar manner. O. Rossii majus and its many hybrids will, as they pass out of flower, require repotting or top-dressing. These plants are best grown in plain, shallow Orchid pans suspended from the roof-rafters. When dealing with specimens with numerous back leafless pseudo-bulbs, and growths that have grown over the sides of the pans, the plants should be broken up, and the back pseudo-bulbs cut away, leaving only three or four behind each lead, making them up again into specimens of the required size. All the Odontoglossums mentioned will succeed well in the warmest position in the cool Odontoglossum house.

SHADING.—Lattice blinds alone will not afford sufficient protection for many occupants of the Orchid houses. At this time of year we may reasonably expect bright sunshine, and it will be necessary to have the roof-glass of nearly all the houses stippled outside. Exceptions are the Mexican and the Dendrobium houses. A mixture of whiting and paraffin will answer the purpose, with the addition of a little clear varnish to cause it to adhere to the glass. Before stippling the glass should be thoroughly washed and allowed to become quite dry. The stippling should be applied as thinly as possible on the houses containing Cattleyas and Laelias, but should be put on more thickly over the divisions containing Odontoglossums, Phalaenopsis, Miltonias, Vandas, Aërides and Saccolabiums. The stippling should be done whilst the sun is shining full on the glass, so that the mixture may dry as quickly as possible.

THE FLOWER GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

DISBUDDING ROSES.—Both standard and dwarf Roses produce certain buds of poor quality, which, if left to grow, are of no value to the plant, and are probably distinctly prejudicial. These are easy to distinguish, and should be rubbed off. Those that are left make stronger growth, and superior foliage and finer blooms are the result. It will be of advantage to most Roses to be surface-dressed with a slow-acting manure, and then to have the surface soil deeply hoed or forked over. See that strong young shoots of climbing varieties are securely fastened.

PROPAGATING SHRUBS.—A number of shrubs may be propagated from cuttings made from soft, young shoots of the current year, and rooted in a heated propagating pit. The best stage is just before they begin to harden, for if too soft they damp off, and if too hard they fail to develop roots. The cuttings should be

not more than 5 inches long, and the usual heel need not be made. I strike them in pure sand kept constantly very moist, and a heavy shade is of value, for if the cuttings are allowed to flag there is slight hope of success, and the shoots from the time they are severed from the parent plant must be kept damp.

Box Edgings and Grass Verges.—The present is the usual time for trimming Box edgings, great consumers of labour in flower gardening, but I have never found it convenient to cut them in this month, some being clipped earlier, others later—so late as September, and those to whom labour presents a difficulty may well leave theirs to the same month. The edgings remain trim and neat for nearly twelve months when cut in that month, and rough parts may be quickly reduced during summer without touching the other parts. Grass verges should be regularly trimmed before the grass makes much perceptible progress. The saving in labour is considerable, apart altogether from the enhancement of pleasure to those who constitutionally dislike untidiness. And so with parts which cannot be reached by mechanical mowing. There is nothing gained by allowing unrestricted growth, and the beauty of specimen shrubs is greatly spoiled by a fuss or more wide band of coarse grass encircling their bases. All this kind of labour may be overtaken after rain, when general garden work cannot be done with profit.

Frost-bitten Shrubs.—The effect of the severe frost in January is now sadly apparent, and Fuchsias, Banksian Roses, Bentbamias, and many other plants will require to have the dead material excised. Where the injury has been very severe the plant should be cut down. Shoots springing from parts which are badly frosted will die back before summer is far advanced. It is better to look closely over the plant and do the necessary pruning now, after which strong shoots will soon appear and take the place of those removed.

Summer Bedding.—A commencement may be made with setting out the less hardy plants, and more particularly if the parts to be filled are sheltered. It was a not unusual custom at one time to delay planting till June, with the result that the plants were half starved through long keeping in pots and boxes, and that many days might be occupied a few weeks later in filling up blanks. The planting of material now that is capable of enduring a slight frost has the further advantage of lessening the strain on labour later, for it is less exacting to plant sectionally and choose one's time for planting than it is to delay till the last moment, and have to take so many days that other work is neglected. The plants that may be put in now are Antirrhinums, Scapdragons, Verbena venosa, Alyssum (Koniga), Phalaris arundinacea variegata (Gardeners' Garters), Gazanias, Silvia patens, Asters, and half hardy plants in general. If possible, choose afternoons for this work and dull weather rather than sunny, the right properly treated, with a good soaking and subsequent hoeing, all should succeed well even in hot weather. Badly rooted plants should be rejected; when used they remain, if they live, a continual eyesore.

THE HARDY FRUIT GARDEN.

By Jas. Hudson, Head Gardener at Gunnersbury House, Acton, W.

Apricots and Caterpillars.—The caterpillar of the Apricot moth is causing some trouble to our trees, but not to a serious extent at present. If the pest seems likely to spread the trees will be sprayed with weak Quassia extract, but I do not like to apply an insecticide of average strength to Apricot trees, and I would be especially loath to do so this spring, as there is a very fair crop of fruit at the swelling stage. Syringing with clear water will be resorted to in the hope of keeping the pest in check. I have been troubled with this same insect in mid-season vineries, the creatures fixing two or more berries together by their web and often eating the skin of the berries, causing them to decay. They cause the same trouble to Apricots. This insect is very active, and drops quickly to the ground.

Black Aphis and Cherries.—The Cherry aphis increases very rapidly, and the dry, easterly winds are favourable to the spread of the pests. The insects may not appear on the trees for a week or two, but a watch should be kept and measures taken at once to check them. It is a good plan to pinch all forelight shoots as soon as the pest appears, for it thrives on these leader shoots more than on any other part of the tree. If the insect is troublesome on other branches they may need dipping in a nicotine solution. The Cherry aphis should never be neglected in the early stages, for it soon disfigures the foliage and also makes the fruits glutinous and sticky; moreover, it is more difficult to destroy when the foliage has developed.

Standard Cherries.—Trees of May Duke and the Kentish varieties of sweet Cherries are covered with a profusion of flowers. For want of opportunity our trees have not been pruned for the past two seasons, hence, no doubt, their profusion of flowers, the trees being still on the young side. Besides flowering so freely, the trees are in the best of health and growing vigorously, for this healthy condition is not due to the use of organic manures; indeed, autumn-fruiting Raspberries are planted under them, so that the soil is not over rich.

PLANTS UNDER GLASS.

By E. Harriss, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Richardias (Arum Lilies).—There are two methods of treating the young Richardias after flowering. One is to place the plants out of doors in a sheltered position and gradually reduce the supply of water until the foliage has died down. They are then turned on their sides for a period of rest, and potted afresh in August. The other method is to plant them out in well-prepared ground, where they are left until there is danger of frost in the autumn. Either of these methods may be adopted with success; the latter probably involves the least labour and in these days of labour shortage this is a consideration.

Humea elegans.—Plants of Humea elegans which were raised from seed sown last year should not be hastened into flower by the use of fire heat. Undue forcing of the plants is the cause of many failures. Let them grow slowly in a cool house and shade them from bright sunshine. Admit plenty of air to the house in favourable weather, leaving the top ventilators open all through the night, more or less, according to the weather. The pots are filled with roots, and stimulants may be used, but not to excess. Seeds may be sown now in shallow pans filled with a light compost for raising another batch of plants to flower next year. Well water the soil previous to sowing and lightly cover the seed with very fine soil. Place the seed pans in a fairly warm house and cover them with sheets of glass, which in turn should be covered with brown paper till the seedlings are through the soil.

Coleus.—To obtain large specimens of good colour grow Coleus in a warm, moist house. Repot the plants when they need more root room, using a fairly substantial compost—a mixture of rich, fibrous loam, leaf-mould, manure from a spent Mushroom bed, wood-ash and sharp sand is suitable. Ventilate the house carefully during the forenoon and maintain a moist atmosphere by damping the bare surfaces in the house frequently. Gradually reduce the amount of ventilation as the sun's power declines in the afternoon, but expose the plants fully to the sunshine at all times.

FRUITS UNDER GLASS.

By W. J. Geise, Gardener to Mrs. Dempster, Keele Hall, Newcastle, Staffordshire.

Melons in Frames.—The present month is a favourable time to start the growing of Melons in frames. Successional crops may be had through the season as more frames become available. The greatest care should be given to the making of the bed and seeing that the fermenting materials are properly prepared. Some growers use stable manure only, but a hot-bed made of Oak leaves and manure in equal proportions retains the heat for a much longer period than manure alone. Well mix the materials under an open shed, allow them to ferment for a few days, and when ready make the bed in the frames. Cover the surface with old turves when the warmth from the bed is suitable, and employ similar soil mixed with old lime rubble as compost for planting. Place the soil in a small mound in the centre of the frame. Plant firmly, but not deeply, and apply light top-dressings of the compost when the roots grow through the surface. Spray the plants twice daily with tepid water and close the frame early in the afternoon. Plenty of heat, and atmospheric moisture, with moderate ventilation, are essential details in the culture of frame Melons. Place mats or other material over the lights at night. Blenheim Orange, Ingestre Hybrid, and Hero of Lockinge are suitable varieties for growing in frames.

The Cherry House.—Established trees in Cherry houses that have passed through the stoning stage must be examined for the active little grubs that do so much damage. A night temperature of 50° to 55° should be maintained, and a little air admitted through the top ventilators. As the sun gains power, and the thermometer rises rapidly, ventilation must be liberally increased. With early varieties a very short time elapses between stoning and colouring, which makes it necessary to guard against aphis attacks before this period arrives. Trees with fruit or nearly ripe fruit should not be fumigated, as the nicotine would injure the flavour of the Cherries. The fruits will hang for a considerable time when ripe, but the house must be kept cool, dry, and well ventilated. If cold, wet weather intervenes, guard against damp by a gentle circulation of warmth in the hot-water pipes just sufficient to keep the house free from moisture. Precautions must be taken to keep birds from the houses by placing small meshed nets over the ventilators.

Plums.—Plum trees growing in borders and carrying full crops of fruit should be mulched and fed with diluted liquid manure, and, occasionally, soot water. Syringe the trees twice daily with clean tepid water, free from lime or other sediments. If not already thinned, the superfluous fruits should be removed at once with a pair of Grape scissors, leaving sufficient to form a crop spread evenly over the trees. Keep all shoots of cordons pinched at the third or fourth leaf, to preserve the symmetry of the trees. Closely pinch the side-shoots of trees trained on walls or trellises to cause fruit spurs to form. The leading shoots may be allowed to grow for some time to come. Plums, like Cherries, are subject to attacks by grubs, aphis, and red spider. The last will not be troublesome where the syringe is used freely. Aphis can be effectively dealt with by fumigation. Soot-water is an excellent stimulant for all stone fruits, and if it is prepared as follows there need be no fear of injury to fruit or foliage (except when the fruit commences to colour, when all syringing must cease). Place about a peck of soot in a sack, weight it so that it will sink to the bottom of a tank or cask of water. Do not disturb the sack, but use the water until it is gone, when the tank should be filled again. The water should show just a tinge of colour.

Peaches and Nectarines.—Young Peach and Nectarine trees require careful attention as regards thinning and tying of the shoots. Guard against over-cropping, and allow a space of at least 4 inches between the shoots. Retain those of medium size, and remove all others. By doing this the shoots that remain will receive more light and air, and the wood for next season's fruiting be better ripened.

Apples and Pears.—When the flowers of Pears and Apples in pots have set, and the fruit commences to swell, lightly spray the trees twice daily with tepid water free from all impurities. Never let the roots suffer from lack of moisture; nor yet be kept in a saturated condition. Light top-dressings or weak stimulants may be given the roots when the fruits are swelling.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER** 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher *Our correspondents would obviate delay in obtaining answers to their communications and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents —*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Local News —*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITORS**, 41, Wellington Street Covent Garden, London. *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 52.5.

ACTUAL TEMPERATURE:—
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday*, May 9, 10 a.m. Bar. 29.7, temp. 60° Weather—Sunshine.

Fruitfulness.

It is curious that our knowledge of the causes of fruitfulness of plants is so meagre. Apart from certain generalisations and beliefs, we really know nothing about it. Why this year the Pears are blossomless we cannot say; all that can be said is that after two good years the trees were exhausted. But in what way are they exhausted? They are making growth, as usual, and hence it must be a specific and not a general exhaustion. The old hypothesis, or rather way of expressing the fact, was that a plant produces a specific flower-forming material—a something which makes a bud become a blossom bud instead of a wood bud; but what that material is, and whether it indeed exists, we do not know.

The common belief that fruitfulness is in some way connected with a more concentrated and unfruitfulness with a more watery sap is probably correct. Actual determinations of concentration of sap, carried out by Mr. C. C. Wigans, of the Missouri Experiment Station, have demonstrated that the cortex sap from bearing spurs of fruit trees is more concentrated than that from non-bearing spurs, and that conversely the leaf sap in leaves of non-bearing spurs is more concentrated than that from bearing spurs; but whether this is a cause or a consequence of fruitfulness remains to be determined. The fascinating researches of Kleb, which have been described fully in these columns, tend to indicate that fruitfulness in the lower plants is associated sometimes with starvation phenomena—the plants become fruitful as their food supplies are approaching exhaustion—and it may be that fruitfulness even in the higher plants is induced by similar causes; as, for example, by a shortage of some special food. This, at all events, would fit in with the fact that when a plant is producing a heavy crop its growth is more restricted than when the crop is short.

The precocious flowering of starved plants is a fact of common observation, and the tendency of plants to bolt after they have sustained a check is another which points in the direction of fruitfulness owing its inception to the lack of something rather than the presence of a special flower-forming material.

But, after all, speculation and guessing, although legitimate in science as a means of jostling the mind out of its ruts, can never by themselves advance knowledge. For that experiment is the only means, and it is to be hoped that when the time comes for the resumption of the pursuit of knowledge some of our investigators will tackle this question of fruitfulness and provide us with the solution of what now remains enigmatical.

ROYAL HORTICULTURAL SOCIETY'S GENERAL EXAMINATION IN HORTICULTURE.—One hundred and thirty-four candidates entered for the Society's General Examination for Seniors, held on March 20, 1918. Four of them, however, were not present on the date appointed, and eleven were not placed. The examiners, the Rev. Prof. G. HENSLOW, M.A., and Mr. JAMES HUDSON, report that of the candidates there were none whose papers were of sufficient merit to warrant a place in the First Class; eleven, or 8 per cent., were placed in the Second Class; and 108, or 80 per cent., in the Third Class. In Section A (Principles), a large number of candidates answered fairly well the first two questions dealing with the nature of the soil, and with the importance of light, their significance in cultivation being understood. In Section B (Operations and Practice), those questions having a bearing on practical work were, on the whole, well understood. Twenty-five candidates entered for the Juniors' Examination, and of these three secured a Second Class, four a Third, and nine a Fourth Class.

MARKET GARDENING ADVISORY COMMITTEE.—Mr. R. E. PROTHERO has appointed a Horticultural Advisory Committee to advise the Board of Agriculture and Fisheries on all questions connected with the promotion of market gardening, fruit growing, and horticulture generally, and, in particular, with regard to the distribution of produce and the organisation of the trades connected with those industries in the situation created by the war. The Committee will be constituted as follows:—Representatives of the Board of Agriculture: Lt.-Col. Sir DAVID PRAIN (Chairman), Dr. F. KEEBLE, F.R.S. (Deputy Chairman), and Mr. A. G. L. ROGERS. Representatives of the Growers: National Fruit Growers' Federation, Messrs. W. COLTHUP, G. F. GLENNY, W. G. LOBJOIT, A. MARSHALL, L. OAKES, and E. S. WARWICK; National Farmers' Union (Kent Branch), Messrs. BERNARD CHAMPION and A. J. RAYNHAM; Horticultural Trades' Association of Great Britain and Ireland, Messrs. A. G. JACKMAN and G. W. LEAK; British Florists' Federation, Mr. G. MONRO; Lea Valley and District Nurserymen and Growers' Association, Mr. JOSEPH ROCHFORD; Market Gardeners, Nurserymen and Farmers' Association, Mr. A. J. LEENEY (Worthing), and Mr. R. R. ROBBINS (Middlesex). Representatives of the Distributors: National Federation of Fruit and Potato Trades' Association, Messrs. ERNEST GLOVER, A. S. HARPER, and THOMAS MAJOR; London Fruit, Flower, and Vegetable Markets Association, Mr. F. R. RIDLEY; London and Provincial Fruit Buyers' Association, Mr. JAMES BRADNUM; London and Home Counties Retail Fruiterers' and Florists' Association, Mr. E. L. VINDEN; Fruit Preservers' Association, Mr. W. R. DEAKIN. Together with Fruiterers' Company, Mr. STANLEY MACHIN; Gardeners' Company, Mr. FRANCIS AGAR; and Royal Horticultural Society, Lord LAMBOURNE and Sir HARRY J. VEITCH. The joint secretaries are Mr. G. P. BERRY and Lieutenant R. WELLINGTON.

WOODLAND INDUSTRIES.—It is remarked in the *Journal of the Royal Society of Arts* that the Forestry Sub-committee of the Reconstruction Committee, in their recent report, state that the wood distillation industry had failed to develop in Great Britain before the war, not because the raw material was not available or too expensive, but because of unscientific methods and lack of encouragement from the Government. The report refers to what has been accomplished by the utilisation of the produce of some 2,000 acres of coppice in the Crown woods at Tintern. Attention is also called to other small industries, including tent-peg and spoke making, that have been set on foot during the war as illustrating the possibility of further utilisation of coppice material.

COFFEE IN BRITISH GUIANA.—The *Journal of the Board of Agriculture*, British Guiana, states that the Coffee industry of the colony continues to increase. In 1905 the area under cultivation was 1,432 acres; in 1910, 2,546 acres; and in 1915, 4,468 acres. The Liberian variety is chiefly planted, as it gives good returns, and costs less to cultivate than the Arabian variety. Most of the Coffee produced in the colony is consumed locally, only a small proportion being exported.

SOIL STERILISATION BY FORMALIN.—For the sterilisation of soil of glasshouses—and, for that matter, small areas in the open—formalin (formaldehyde) is said * to give valuable results. The solution should be made by mixing 3½ pints of formalin (commercial 40 per cent.) with 50 gallons of water, and used at the rate of 1 gallon to the square foot.

NEW FOOD PRODUCTS.—The Council of the Royal Society has appointed a committee to investigate and report on the possibility of obtaining and replacing food materials and other necessaries by the utilisation of natural products not hitherto generally employed for such purposes. Suggestions as to such products and the means of organising their collection should be addressed to the secretary of the Natural Products Committee, Royal Society, Burlington House, Piccadilly, London.

WAR ITEMS.—We deeply regret to learn that Lieut. ARTHUR BARNES, eldest son of Mr. N. F. BARNES, Eaton Gardens, Cheshire, has been killed in action. Lieut. BARNES formerly served in the Royal Horse Guards (Blue), and received his commission in the Cheshires. He had been acting captain some time, and was about to be gazetted to that rank.

—We regret to learn that Lieut. JOHN O'BRIEN, son of Mr. JAS. O'BRIEN, was wounded in the left hand in action on April 30, in Portuguese East Africa. The wound is not expected to prove dangerous.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

Plums in Pots. This spring our earliest plants in pots have set a most abundant crop of fruit. Our usual method of fertilisation, by employing a hive of bees, was practised. No actual forcing has been attempted, as these trees, after having been forced for twenty years, come to bloom almost of their own accord, but in a temperature at least a few degrees above freezing point has to be maintained. We never had a greater profusion of fruit upon Count Althann's Gage or Early Transparent Gage. Other Transparent Gages, Kirke's Early Prolific Jefferson, and Blue Rock, have also set well. *J. H. Ivins, Gannochy, Hoose, Gardens, Perth.*

Manuring Experiments on Fruit. A sentence in Jethro Tull's *Horse-Hoeing Husbandry*, which I happened to take up just after reading the article on "Manuring Experiments on Fruit," on p. 135, set me wondering on what plan the plots had been laid out at the Ridgmont Fruit Farm. The sentence was in reference to the tap-root: "This tho' it goes very deep has horizontal ones passing out all round the Sides and extend to several Yards Distance from it, after they are be their Moisture, and rotten Timber become invisible to the naked Eye." I wondered what precautions had been taken to prevent the invasion of the plot to which one kind of manurial treatment had been given by those roaming roots from a neighbouring plot to which another was driven? In the Report No. 15 (1916) there are many experiments to learn that in the Ridgmont soil fruit trees assume "a remarkable shallow rooting habit" as is only to be expected, for the depth to which roots may penetrate depends largely upon the presence or absence of air, and in Ridgmont soil is, one may suppose, very wet at a little below but beyond telling us that there were 21 plots of 18 trees of certain varieties on paradise stock the report is silent. The first report, however, shows us that each "plot" consisted of a single line of trees planted 11 feet from the lines on each side of it. The trees in one line received one dressing, those in the next another. Other details are to be learnt from the first, second, fourth, and ninth reports, and they go to show that the roots spread far, but there is nothing whatever to show that the roots of one line of trees did not benefit or suffer, as the case may be, from the treatment of the lines on either side at least. It is a pity this point seems to have been overlooked in the compilation of the reports, for those who are seriously occupied in the growing of fruit are desirous of knowing the conditions under which experimental results have been obtained, and here is one which seems to render doubtful the validity of the whole of the conclusions based upon the results of manuring at Ridgmont. To point to the Millbrook experiments where positive results were evident in somewhat similar circumstances, will not explain away this disturbing factor, for there the soil is very different, and probably the nature of the root development will also be different too. Another omission seems regrettable, too. We are given comparisons between the crops, but nowhere can we discover an indication of the actual yields the trees are giving. No system of manuring will compensate for treatment detrimental to the trees in other directions, and the enquiring fruit grower would have welcomed evidence to show that the trees normally treated at Ridgmont were producing annually crops such as might reasonably be expected from trees of their variety and age. Such a statement would have been more illuminating than the figure 100 used as a basis for the "normal" trees, and would have tended to allay any fear the reader's mind might harbour that perhaps the lack of response to manuring was due to some other disturbing factor in the tree's growth. It is to be hoped that further experiments may be set afoot ere long where precautions are taken to prevent the treatment of one plot influencing the trees on another, for the question of the need for manure in the fruit plantation is one of immense and increasing importance, for fruit growing is increasing, and supplies of stable and farmyard manure are decreasing. *F. J. C.*

SOCIETIES.

ROYAL HORTICULTURAL.

May 7.—The fortnightly meeting in the Drill Hall on Tuesday last was the most successful for many months past. The exhibition was sufficient to fill the large building, and there were numerous visitors. The importance of the meeting was largely accounted for by the fact that the National Rose Society had arranged a number of special classes for Roses. This gave raisers the opportunity of showing their new seedling varieties, which they have hitherto been able to do at their own spring Rose shows, which, of course, this year, on account of the cold

The Floral Committee recommended three Awards of Merit to new plants and awarded seven medals to collections.

Messrs. Barr and Sons' exhibit of Daffodils and Tulips was the best group in the section, and the Committee gave an Award of Merit to a seedling Daffodil shown by the same firm. The Award of Merit given to Narcissus Crimson Beacon (see p. 181) at the last meeting (see p. 181) was raised to a First-class Certificate.

Floral Committee.

Present:—Messrs. H. B. May (chairman), J. Cheal, S. Mortimer, G. Routhe, R. C. Notcutt, W. J. Bean, J. Hudson, C. R. Fielder, W. Howe, J. Jacques, A. Turner, H. J. Jones, C. Dixon, J. Douglas, W. P. Thomson, E. H. Jenkins, G.

Fig. 89.—TWO NEW GOLD MEDAL ROSES.

Above—Lyon Garden (crimson). Below—Frances Gaunt (apricot colour). (See p. 201.)

tions. The National Society's Gold Medal was awarded to two new varieties, and Certificates of Merit were awarded to several others. Groups of Roses were exhibited by traders and others, and received awards from the National Rose Society.

Exhibits before the Floral, Narcissus and Tulip, and Orchid Committees were of a high standard.

There was one exhibit of especial importance—two hundred seedling Potatos from Messrs. Sutton and Sons—before the Fruit and Vegetable Committee. The exhibit was given a Certificate of Appreciation.

The Orchid Committee awarded a Cultural Certificate to Mr. Collier for a magnificent plant of Laelio-Cattleya J. E. Bickleck, Fowler's variety, and four Medals to groups

Paul, W. Cuthbertson, J. F. McLeod, W. Mouter, Jas. Hudson, and H. Cowley.

Awards of Merit.

Rhododendron Royle magnificum.—A glorified form of the hardy Chinese species R. Royleï; the flowers are both larger and brighter in colour than those of the type. The interior of the blossom is salmon-pink, which darkens on the outside towards the calyx tube to rich crimson, with a bluish bloom. Trusses contain from five to six of the wide-spreading, pendant blossoms which are well set off by the handsome leaves, silvery grey beneath and Holly green above. Exhibited by Mr. G. Reuthe.

Primula spicata.—This species has the appearance of a miniature P. mutans, but the flowers are held more erect. They are a beautiful shade of

lavender blue, with a white interior; both flower-stem and calyx bear white farina. The foliage closely resembles that of the common Primrose, but is much smaller, and is delicately pilose. The species is a native of China, and was introduced by Mr. Geo. Forrest. It will be very suitable for growing in the Alpine house, or in parts of the rock-garden where its delicate beauty will not be overlooked. Shown by Messrs. R. WALLACE AND CO.

Polyanthus Miller's Giant.—The award was made for a large-flowered strain of Polyanthus, with the usual wide range of colouring seen in this spring flower, including blue, primrose, yellow, crimson, and maroon. Exhibited by Mr. G. W. MILLER.

GROUPS.

R. L. MOND, Esq., Combebank, Sevenoaks (gr. Mr. C. Hall), filled one of the long tables with plants of *Calceolaria Clibranii*, a beautiful hybrid raised in the John Innes Institute, Merton. The plant is excellent for the greenhouse or conservatory; it bears lax trusses of clear, rich, self-yellow flowers. The plants shown were remarkably well grown, and were awarded a *Silver-gilt Banksian Medal*.

Mr. L. R. RUSSELL, Richmond, showed ornamental-leaved and flowering shrubs, for which a *Silver Flora Medal* was awarded. Japanese Maples were a feature of this group, and acted as foils to Laburnums, Wistarias, and Cytisus praecox in bloom.

Messrs. H. B. MAY AND SONS were also awarded a *Silver Flora Medal*. Their exhibit consisted of indoor Ferns, interspersed with bright groups of flowering plants, such as Verbenas, Hydrangeas, Clematis, and scarlet Salvias.

Silver Banksian Medals were awarded to Messrs. STUART LOW AND CO., for Perpetual-flowering Carnations; Mr. G. W. MILLER, for hardy flowers; Messrs. PIPERS, for hardy flowers and flowering shrubs, which included a magnificent specimen of Enkianthus campanu-

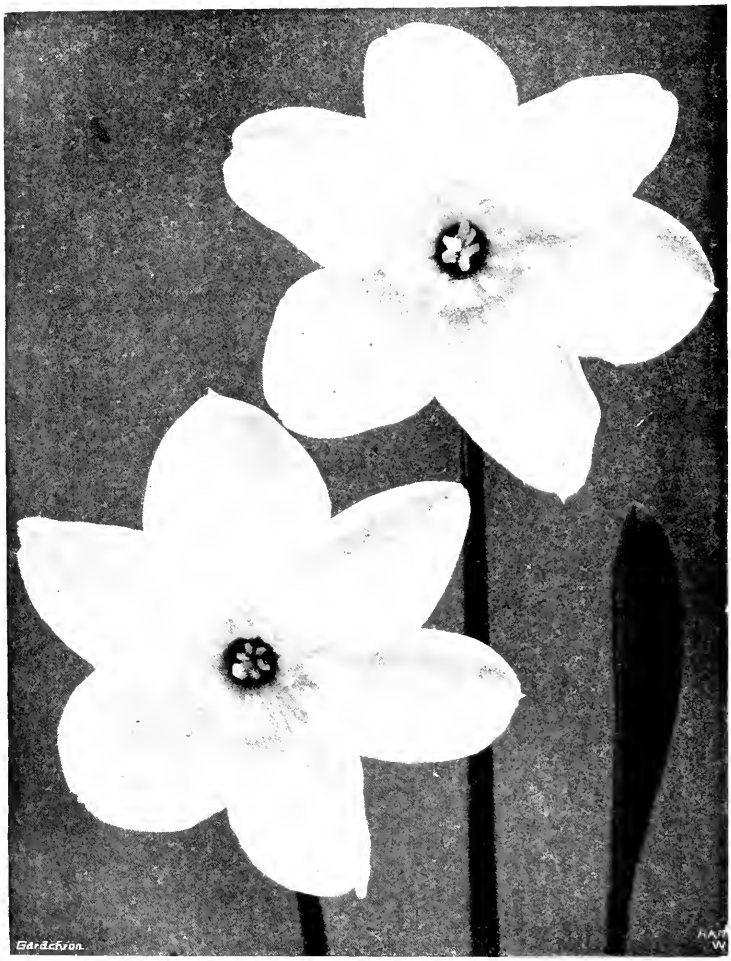

FIG. 87. NARCISSUS ANCHORITE.

(See Awards by the Narcissus Committee.)

latus and Schizandra chinensis rubra; and Mr. G. REUTHE, for hardy plants, Rhododendrons, and uncommon shrubs. The Rhododendrons were the chief feature of Mr. Reuthe's exhibit; besides the fine form of R. Roylei which gained the Award of Merit, he showed the curiously flowered R. spinuliferum, which has fleshy-coloured flowers, ovate in shape, not expanding at the mouth, with the stamens protruding a considerable distance from the apex; and R. campylocarpum, the finest of all yellow-flowered Rhododendrons.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Sir Harry J. Veitch, Messrs. Jas. O'Brien (hon. secretary), R. Brooman-White, Walter Cobb, W. H. White, W. J. Kaye, J. Charlesworth, Arthur Dye, T. Armstrong, E. R. Ashton, Pantia Ralli, Frederick J. Hanbury, Stuart Low, R. A. Rolfe, Fred K. Sander, and C. J. Lucas.

AWARDS.

CULTURAL COMMENDATION.

To Mr. J. COLLIER, gardener to Sir Jeremiah Colman, Bart., Gatton Park, Surrey, for a plant of Laelio-Cattleya J. F. Birkbeck, Fowler's variety, with six grand flowers, one spike bearing four blooms. The same plant was shown by the late Mr. J. Gurney Fowler on March 30, 1915, when it was unanimously awarded a First-class Certificate. In Mr. Collier's hands it has greatly improved beyond its then fine form.

The cross is between Cattleya Mendelii and Laelio-Cattleya Henry Greenwood (L. C. Schilleriana × C. Hardyana), and it appears to have developed the good qualities of all the parents. The sepals and petals are white with a slight blush tint, the labellum ruby-crimson with gold lines from the base to the orange-shaded centre.

NOVELTIES.

SIR JEREMIAH COLMAN showed Odontoglossum Gatton Princess (Queen of Gatton × eximium). The plant had a fine spike of well-formed, light yellow flowers, which are profusely spotted with dark purplish-red. The lip is white, and has a dark red blotch in front of the yellow crest.

A. P. CUNLIFFE, Esq., Woodford, Salisbury (gr. Mr. Tindall), showed a remarkably fine form of Cattleya Tityus (Enid × Octave Doin). The large, bright, rose-coloured flowers have a ruby-crimson front to the lip.

GROUPS.

Messrs. ARMSTRONG AND BROWN were awarded a Silver Flora Medal for a group of Odontoglossums, Odontiodas and Miltonias. Among the Odontoglossums were several handsomely blotched *O. crispum* raised from home-raised seed, and other showy hybrid Odontoglossums. Miltonia Frank Reader, a large, rose-pink flower with dark, ruby-crimson mask on the lip, and Odontioda Henryii, with a fine spike of orange-scarlet flowers, were the most striking plants in their respective sections.

Messrs. CHARLESWORTH AND CO. were awarded a Silver Flora Medal for a group of handsome Odontoglossums and other showy varieties. Odontoglossum Dorcen (*eximium* × Empress of India), a pretty seedling, bore one large white flower prettily marked with light purple; Odontioda Joan variety, with dark lilac flowers, Oda Brewer, and forms of Cattleya Tityus, were specially attractive.

Messrs. STUART LOW AND CO. were awarded a Silver Flora Medal for a varied and interesting group which included several rare species. *Dia crium bloomfontum*, with pure white flowers, and several bright red Renanthera Imschootiana, showed up well, whilst among the hybrids the finely formed Laelio-Cattleya Moonbeam (C. Schroderae × L. C. G. S. Ball), with clear apricot-yellow flowers having an orange centre to the lip, and Odontoglossum Oberthürii (Adrianae × harvengtense), with handsome light canary-yellow flowers spotted with chestnut-red and well-rounded labellum, gave good examples of the hybridist's success.

Messrs. C. E. WATERS AND CO. were awarded a Silver Banksian Medal for a group of well-flowered Dendrobiums, with Cattleyas, Brasso-Cattleyas, and Odontoglossums.

Narcissus and Tulip Committee.

Present: Mr. E. A. Bowles (in the chair), Rev. Joseph Jacob, Miss Willmott, Messrs. W. Poupart, W. B. Cranfield, R. W. Wallace, Peter B. Barr, Herbert Smith, G. W. Leak, F. Herbert Chapman, J. T. Bennett-Poë, R. A. Wallace, and Chas. H. Curtis (hon. sec.).

AWARDS.

FIRST-CLASS CERTIFICATE.

Narcissus Crimson Braid.—This fine Barrii form, which gained an Award of Merit at the meeting held on April 23 last (*see Gard. Chron.*, May 4, 1918, fig. 83), was given the higher award of a First-class Certificate. Shown by Messrs. HERBERT CHAPMAN, LTD.

AWARD OF MERIT.

Narcissus Anchorite (see fig. 87).—A large flowered bicolor Barrii variety having blooms

about 3¼ inches across. The perianth is white and well formed, and the cup is bright pale yellow, beautifully trilled and lending its colour to stain the bases of the perianth segments. It is a tall-growing form, averaging about 19 inches in height. Shown by Messrs. BARR AND SONS.

GROUPS.

The most important group was staged by Messrs. BARR AND SONS, and was composed of Tulips and Daffodils. The former flowers were rather small and dark-coloured varieties predominated, notably La Tulipe Noire, Zulu, Valentine, Viking, and Sirdar. Tulipa viridiflora praecox was also included. Among Daffodils, a greenish-yellow trumpet seedling was conspicuous, with Anchorite, White Lady, Thisbe, and Minerva, the latter a very neat Poet's Daffodil, not far removed from N. poeticus of Linnaeus. Silver-gilt Banksian Medal.

Narcissus Crimson Braid was shown in grand condition by its raisers, Messrs. HERBERT CHAPMAN, LTD. The same firm staged a bunch of flowers of the Narcissus poeticus of Linnaeus. This form was thought to have been lost to cultivation, but Mr. William Poupart, Twickenham, had a small stock, and distributed a few bulbs to friends, and it was from this stock that the flowers shown were produced.

Mr. W. B. CRANSFIELD, Enfield Chase, exhibited up a few seedling Daffodils, notably Cantata, a bright-eyed Poeticus variety, and Cansonet, a bicolor Barrii of considerable beauty and substance.

Fruit and Vegetable Committee.

Present: Messrs. A. H. Pearson (in the chair), J. Harrison, W. Bates, W. H. Divers, A. Bullock, E. Beckett, G. Kelf, O. Thomas, A. R. Allan, E. A. Bunyard, H. S. Rivers, Jos. Cheal, and W. Wilks.

Messrs. SUTTON AND SONS contributed an exhibit of much interest and value—a selection of two hundred seedling Potatos of their "Casbi" strain. These represented the selection of 70,000 crosses, and including first-early, second-early and maincrop varieties. None of the varieties was named, but we understand that all have shown the desirable qualities of productiveness, flavour, and robust constitution after trials extending over a number of years. (Certificate of Appreciation.)

NATIONAL ROSE SOCIETY'S CLASSES.

THE National Rose Society arranged a number of classes for Roses in connection with the Royal Horticultural Society's fortnightly meeting on Tuesday last. There were no money prizes, but each exhibitor was allowed to show his flowers as he pleased.

There were three nurserymen's groups, of which that staged by Mr. ELISHA HICKS was particularly pleasing. The centre consisted of a large group of Mojesti (a very deep and perhaps slightly sombre colour when grown under glass), which was brightened by a pretty bank of R. Harrisoni, with its cheerful yellow flowers and small decorative foliage. Flanking this group were two stands of Mrs. Elisha Hicks, Joanna Bridge, the fragrant Mrs. George Norwood on the one side, and on the other Mme. E. Herriot, and a particularly bright pillar of the dwarf Polyantha Ellen Poulsen, which seems to be as good under glass as it is in the garden.

Messrs. B. R. CANT'S group included several Roses of interest. In the centre was a large group of Dr. Williams's climbing Rose, Emily Gray, with deep yellow flowers and large foliage of the Noisette type. It has a certain, though not pronounced, fragrance of its own, and is a colour that has long been sought for in a climbing variety for the garden, Maréchal Niel, alas, being useless to most of us, except under glass. There was here also a good stand of Golden Ophelia and one of Augustus Hartmann. The attraction of this Rose lies in its brilliant colouring, and it was no surprise to find the shade of the petals as grown under glass even more brilliant than when grown in the open. This fine variety has, unfortunately, a certain dislike of transplanting, and many seem to have failed with it through not pruning sufficiently hard after moving it.

Messrs. PAUL AND SON, Cheshunt, showed a fine group of standards and pot Roses, among which Ethel, Mme. Segnad Weber, Edward Mawley, and G. C. Ward were specially worth notice.

The exhibits of amateurs were not numerous, but Mr. E. J. HOLLAND showed a few exhibition blooms in baskets and vases showing great perfection of culture. Some wonderfully fine blooms of Mrs. Foley Hobbs were contained in one basket, while Mrs. Welsh, William Shean, and Edgar Bamber were also noticeable, both for large size and the nicely formed character of the flowers.

Mrs. O. FISHER showed a beautiful bowl of Ophelia, and Mrs. COURTNEY PAGE two bowls, of which that containing Melody was particularly pleasing.

SEEDLING ROSES.

Seedling Roses always attract attention, and several of those displayed were worthy of something more than passing notice. All those exhibited were of the H.T. section.

The first and perhaps the most perfect in form was Mrs. Elisha Hicks. This Rose possesses a delightful fragrance, which brought one back several times in the day to inhale its sweet perfume. The colour is a soft blush pink, very clear and delicate, and the growth seemed of a satisfactory character. The variety was awarded a Card of Commendation.

A Gold Medal was awarded to Messrs. B. R. CANT AND SONS for a crimson variety named Covent Garden seedling, 36, of a colour near that of Hoosier Beauty, but practically without perfume. They were also awarded a Card of Commendation for Golden Ophelia, which is a well-formed flower, carried well on good stiff stalks of a bright golden colour. The variety was probably not shown quite at its best, and when this occurs it should secure the Gold Medal without difficulty.

Messrs. A. DICKSON AND SON exhibited several new Roses. They were awarded a Gold Medal for a decorative Rose named Frances Gaunt (see fig. 36), of a pinkish apricot, almost orange-coloured flower of moderate form. The award received some criticism, but was probably justified by the colour, which certainly looked well in the mass, and seemed to improve on a second and third visit.

A more beautiful flower of excellent form was Molly Bligh, which received a Card of Commendation. The colour is pink with a tinge of apricot and a suspicion of brick-red shading, and the flower reminded one, both in colour and form, of that finely formed Rose, Lady Moyra Beauclerc, and like this Rose, it seemed to have the defect that the edges of the petals are easily injured. Notwithstanding this fault, it is a lovely flower, which one could visit again and again with an increasing satisfaction, which was not diminished by its pleasing perfume.

Chameleon is a fairly well formed flower of a distinct orange or strawberry pink colouring, of medium size, and Mrs. Dunbar Butler a pretty pink form. *White Rose.*

CROPS AND STOCK ON THE HOME FARM.

SUMMER FALLOWS.

THE summer fallow is an old-fashioned method of cleaning land and laying a thorough foundation for a future Wheat crop. Some think such a method of Wheat preparation a waste of land, yet the plan cannot be surpassed. They prefer to sow some catch crop, even if the land is foul, in which case it will always be weedy, undesirable ground. It is much better to summer fallow such land and thoroughly clean it once for all. Plough sufficiently deep to get under the roots of the Couch, cross plough within a short period, drag over the surface to disintegrate the soil and get the Couch on the top, harrow to further remove the soil, and roll the surface if the ground is cloddy. Collect the rubbish by the aid of chain harrows, and burn it in small heaps over the ground. When this is completed, plough again to disturb any roots missed the first time, and repeat the collecting and burning process. All such work needs to be done in dry weather to be effective.

STIMULATING THE OAT CROP.

Where Oats were sown on newly broken up pasture and especially where manure was not added at sowing time, I note in many cases the Oat plant needs some assistance to enable it to develop vigorously, especially where wireworm is prevalent. No time should be lost in assisting the growth by sowing evenly over the surface 1 cwt. sulphate of ammonia per acre.

POTATOS.

No time should be lost in completing the planting of the Potato crop. The land is now working well, except in a few instances where the soil is heavy. Turf land newly broken in January has come to hand remarkably easy, and the promise of crops under such conditions are favourable. The early plots, whether on the flat or in ridges, should now be harrowed over to kill the first crop of weeds, loosen the soil, admit air, and enable the cultivator or horse-hoe to run the more freely between the rows later.

SUGAR BEET.

There seems to be a prospect of factories being erected in various parts for the manufacture of sugar from Sugar Beet. If this suggestion is to be practical then the growing of Sugar Beet will be encouraged, because, with a reasonable prospect of a fair return, farmers will grow the crop.

During the past two years I have proved that Sugar Beet can be grown successfully in this county. I have at the present moment many good roots still in the ground, which I fear I shall have no use for, as although horses, pigs and cattle eat them willingly, they cannot consume so many as I have grown. The middle of the present month is a good time to sow the seed, at the rate of 6 lbs. per acre, drilled like Mangold or even a trifle closer. The deeper the land is broken and disintegrated the better, as more roots are made than in the case of Mangold. Manure, too, should be evenly distributed, whether it is farmyard dung or superphosphate; the latter should be sown over the plot at the rate of 4 cwt. per acre.

THE GOVERNMENT DRAINING SCHEME.

I am pleased to see that the much needed legislation for dealing with land drainage is on the taps, and likely to come into effect. One point which ought not to be lost sight of is the neglect of farmers to clean out ditches and watercourses. I come across many instances of this while inspecting farms with a view to the ploughing of grass land for corn crops. Too many farmers, as an excuse for ploughing grass land, point to the wet condition of the soil, but they forget to say this is caused by the neglect to keep the ditches clean. Where farms are situated on hills there does not seem to be much excuse for having wet fields if reasonable attention is paid to the natural watercourses. *E. Molyneux.*

LINSEED.

THE Food Production Department strongly recommends farmers to grow a small area of Linseed this year. The crop is particularly suited to the circumstances of the present time. It should be sown about the middle of May. The crop is practically immune from wireworm, and may therefore be taken after old grass or used for filling up a thin corn crop or replacing one that has failed. When it is too late to sow Barley, there is still time enough for Linseed. The possession of even a small quantity of Linseed next autumn should go far to solve the difficulties at present attending the rearing of calves. It is particularly rich in oil (35 per cent.) and in albuminoids (23 per cent.). A pound of Linseed is for general purposes equal to nearly 2 lbs. of Oats or 1½ lb. of the best oilcake or cereal food. In addition to this, Linseed is a crop that can be cultivated easily. A fine surface tilth and a light covering are all that it needs. It is suited to most parts of the country and to most soils.

There should be no difficulty in securing seed. Stocks of both home-grown and Argentine Linseed suitable for seed are available. Particulars as to the price may be obtained from the Controller of Supplies, Food Production Department, who will also forward on application a memorandum giving full information as to the cultivation and uses of Linseed.

REMARKS.—The market is well to very supplied with blooms, but prices remain high, more especially for white flowers. A few boxes of the double white Narcissus flore pleno Narcissus poeticus White Stock and Red Inia, Iceland Poppies, and Gypsophila are coming in, received from the Scilly Isles in excellent condition. Red Roses are scarce. Carnations are good, and sufficient for the demand. Sweet Peas and Lilium longiflorum are good and clean. There are abundant supplies of Darwin Tulips principally from out of doors. Daffodils are almost finished, but good blooms are still being sent from Scotland. The chief varieties are Emperor and Victoria which had a ready sale.

REMARKS.—Apples from all sources are now practically exhausted. Supplies of Black Grapes are increasing daily. Muscats are also on offer. Supplies of Peaches, Strawberries, Figs, and Melons all show an increase. Tomatos (English and Channel Islands), Peas, Beans, Marrows, and Cucumbers are all more plentiful. Mushrooms continue a fair supply. Green Gooseberries are fairly plentiful. Asparagus (French), Cavaillon and Lauris is getting scarcer, but consignments from Worcester are now reaching the market. The market is well supplied with Long Scarlet and Turnip Radishes. Lettuces, Spring Cabbages, and Cauliflowers are all plentiful. *E. H. R. Covent Garden Market, May 8, 1918.*

Obituary.

MAURICE DE VILMORIN.—The funeral of Monsieur Maurice de Vilmorin, whose death on April 22 we announced in our last issue (p. 192), took place in Paris on April 29, in the presence of a large and distinguished gathering. Maurice de Vilmorin was in his 70th year. He was a son of the great French biologist and agronomist, Louis de Vilmorin, brother and uncle respectively of the late Henry and Philippe de Vilmorin; co-proprietor of the firm of Vilmorin, Andrieux et Cie; vice-president of the French Société Nationale d'Horticulture, of the Dendrological Society, and of the Acclimatisation Society, and a member of the Academy of Agriculture, of which he was president in 1915. His name, however, will be chiefly famous as that of a dendrologist. His connection with French missionaries such as the Fathers Delavay, David, Farges, and Soulie enabled him to introduce into Europe numerous plants, and in particular flowering shrubs, of which many were exhibited at the Quinquennial Floralies at Ghent in 1908 and 1913. We may instance, among his most remarkable introductions, Buddleia variabilis, Buxus Delavayi, Davidia involucrata, and Rosa Soulieana. He took over for his own use—particularly as regards the shrubs—the collections of Alphonse L. Lavallée at Segrez, which would otherwise have been dispersed, and created, in 1904 the well-known Fruticetum of Les Barres, near the celebrated Arboretum planted by his grandfather Philippe André de Vilmorin; in which he brought together the most important known collection of the flowering shrubs of temperate regions. The catalogue—*Enumeratio Vilmorinianum*—was published in 1904 with the aid of Monsieur Bois. Maurice de Vilmorin leaves two children. The eldest, Jacques de Vilmorin, is one of the present heads of the firm of Vilmorin, Andrieux et Cie.

GARDENING APPOINTMENTS.

Mr. **W. R. Wright**, for the past 2½ years Gardener to Major P. L. T. Hibbert, Ashby Saint Ledgers, near Rugby, Northamptonshire, as Gardener-Bailiff at the same place. [Thanks for 2s. for R.G.O.F. box. Eds.]

Mr. **Robert G. Martin**, for the past 9 years Gardener to Lord Wimborne, Ashby St. Ledgers, Rugby, as Outdoor Superintendent and Horticultural Instructor at the Horticultural College, Swanley, Kent.

THE WEATHER.

THE WEATHER IN SCOTLAND.

April was a bright, dry month, with an average mean temperature. Easterly winds prevailed during the month, chiefly from the north-east. Rain fell on ten days, five of which were "rain days," the total fall being 0.85 inch. The greatest fall on any one day was 0.26 inch on the 5th. Snow fell continuously for five hours on the 20th. Of sunshine 186 hours were recorded, being on average of 6.2 hours per day, and a percentage of 43.8; there were only three sunless days. With a mean of 30.152 inches, the barometer varied between a highest of 30.455 inches on the 23rd, and a lowest of 29.315 inches on the 1st. The mean temperature for the month was 45°; the mean range being 16°, and the absolute range 37°. The highest maximum of 62° was on the 27th, while the lowest minimum of 25° occurred on the 16th, while the lowest maximum of 42° and the highest minimum of 44° were on the 14th and 28th respectively. On four nights the thermometer fell below 32°. On the grass the mean minimum was 29°, with a lowest of 19° on the 16th. There were sixteen nights of ground frost. At 1 foot deep the soil temperature, with some fluctuations, rose from 45° to 47°. *James Malloch, Director of Studies, St. Andrews Provincial Training College Gardens, Kirkton of Mains, near Dundee.*

ANSWERS TO CORRESPONDENTS.

BEES: *Markets.* Place the sections in the hive when the bees are ready for them. When these sections are nearly filled with honey, put another crate underneath. You should use queen excluders, otherwise the brood will be raised in the sections.

FLUE DUST: *J. H.* Since the flue dust apparently contains a high percentage of potash, it will be especially valuable for Potatos, and can be spread over the ground at the rate of 3 or 4 ozs. to the square yard, as well as being dusted in the trenches when the sets are being planted. For mixing with potting compost, use a fair-sized flower-potful to a barrow-load of soil.

JAM: *Mrs. S.* Green Gooseberries make excellent jam, but naturally they require more sugar than ripe ones, and they are more likely to ferment. Jam is inclined to become mildewed on the top if it is kept in a damp place, and also if the cover was not sufficiently air-tight. The best way to cover jam is to pour hot mutton fat (or other fat) on the top when the jam is quite cold. This solidifies, and keeps the air out; the jars can then be tied down with paper or not, as preferred. In any case, ordinary paper is not airtight, and if that alone is used the jam is liable to become attacked by mildew.

MARKET VEGETABLES: *H. R. W.* A bundle of Asparagus contains approximately 120 shoots. The number of roots in a bunch of vegetables are: Carrots, about 12; Horseradish, 12 to 18; Leeks, 6 to 12; Onions, 3 doz.; Radishes, 1 doz. to 2 doz.; Turnips, 1 doz. The ordinary size of a bunch of Mint or Thyme is a handful. A "strike" of Parsley is about 6 lbs. weight. A "tally" of Cabbages is 60 head.

MEALY BUG ON CACTUS: *J. H.* Mealy bug is a troublesome pest on Cactaceous plants, as it usually harbours in the clusters of spines. Syringing is very little use; the best way is to use a small, stiff brush, dipped in insecticide, and with this thoroughly clean the plants. Diluted petroleum is an effective insecticide.

NAMES OF PLANTS: *C. F. W.* 1, Dendrobium Ainsworthii splendidissimum (aureum × nobile); 2, Dendrobium Wigandianum (Hildebrandii × nobile).—*L. W. Y.* Viburnum Sandankwa, a Japanese species.—*T. L., Ireland.* Amelanchier canadensis.

SCALE ON PEACHES: *Miss P.* Thoroughly moisten the surface of the bark with a lather composed of soft-soap and water, and then scrape the surface with a blunt knife, or rub with a piece of coarse canvas, so as to clear off the scales without injuring the bark. Afterwards apply by means of a brush a mixture of 2 lbs. of soft-soap to 1 lb. of flowers of sulphur, thoroughly mixed with about 14 gallons of water; or, if you have not many trees, you can make a smaller quantity, but do not vary the proportions. You should do this at once, as the young insects creep out from under the dead scales in May, ready to begin a new attack.

NOTES FROM KEW.—V.*

THERE has been remarkably little advance in vegetation since my last notes appeared. The cold east winds, coupled with lack of sunshine, have retarded growth at a time of year when it is usually on the rush. However, it has been all for the best. Vegetation is quite forward enough, as there may be frosts before this month is out; the Potatos on the Palace lawn are above ground, and many other plants are uncovered to frost attack. The flower garden in front of the Palm House is planted with fifty thousand seedling Onions, and the flower-beds elsewhere are being sown or planted with other vegetables, including such out-of-the-way things as Sweet Maize, Ground Nut, Chinese Cabbage and Caraway. The last-named has been the subject of frequent inquiry at Kew. Oil of Caraway (Carum Carvi) is used in medicine and as a perfume for soaps; the popular liqueur Kummel is flavoured with it, and, as everyone knows, the seeds are used for flavouring cakes. The plant is as easy to grow as Parsley; it is, indeed, a Parsley in habit. Seeds nowadays are not to be had, unless one can find them in the spice-chest of a careful housewife, as Kew did, after trying Messrs. Vilmorin and other seed merchants unsuccessfully.

The garden attached to No. 1 Museum, formerly the residence of the Duke of Cambridge, is planted with a selection of drug and other plants of economic importance. Generally, each kind occupies a separate bed on the lawn, so that those interested may see what the plants are and obtain some idea of their cultural requirements. Here is a list of them:—Aconitum Napellus, Achillea Millifolium, Acorus Calamus, Agrimonia Eupatoria, Agropyron repens, Althaea officinalis, Anthemis vulgaris, Artemisia vulgaris, A. Abrotanum, A. Absinthium, Asperula odorata, Arctium Lappa, Atropa Belladonna, Calendula officinalis, Carum Carvi, Chelidonium majus, Chrysanthemum Parthenium, Colchicum autumnale, Convallaria majalis, Datura Stramonium, Daucus Carota, Digitalis purpurea, Foeniculum dulce, Gentiana lutea, Helleborus niger, Hydrastis canadensis, Hyoscyamus niger, Hyssopus officinalis, Lavandula officinalis, Lamium album, Leonurus Cardiaca, Linum usitatissimum, Marrubium vulgare, Mentha piperita, M. viridis, Melilotus officinalis, Melissa officinalis, Nepbrodium Filix-mas, Papaver Rhoeas, P. somniferum, Pimpinella anisum, Pyrethrum Parthenium, Pyrus Cydonia, Ranunculus Ficaria, Rheum officinale, Rosmarinus officinalis, Ruta graveolens, Spiraea Ulmaria, Stachys Betonica, Symphytum officinale, Tanacetum vulgare, Taraxacum officinale, Teucrium Chamaedrys, T. Scorodonia, Tussilago Farfara, Valeriana officinalis, and Verbena officinalis.

An Aristotelian garden this, with no interest whatever for the "decorative" gardener, who scoffs at beds of Dandelion and Tansy. All the same, it has a real value to those who desire to know the official plants. Modern gardening has gone too far in the direction of the merely ornamental. The beautiful wild Cherries, Pears, and Plums at Kew have few equals, but if one goes where fruit orchards abound one will see acres of such displays of flowers, and they will be succeeded by crops of fruit as pleasing to the eye as they are useful as food. If, instead of the Lime, Hawthorn, Laburnum, Lilac, Laurel, Aucuba, and the pestiferous Privet which fill so much space in the gardens of to-day, we had Apples, Pears, Plums, Cherries, Currants, Gooseberries, and some of the best Blackberries, our gardens would be none the less beautiful and the flowers would be followed by fruit which is good for man. Too much art, too little common sense, is a fair criticism of much of our gardening efforts. Of course, when a man owns sufficient land to be able to indulge in the merely beautiful as well as the really useful, he is lucky, but there are thousands who can only afford one phase of gardening, and it is unfortunate that they usually prefer the wrong one. It really is astonishing how rapturous we can grow over plants that are little better than weeds. The early English gardeners cultivated only plants that had a direct economic value, and we moderns might very well take that leaf out of their book. This is rank heresy, no doubt; still, it has to be said by someone, and I might as well say it.

There is no better hedge plant than Berberis stenophylla. At Kew this shrub is represented by large masses in prominent positions, but it is turned to useful purpose as a hedge enclosing the hardy aquatic garden, and a most perfect hedge it is. It can be sheared as Privet and Thorn are, and it quickly becomes a wall-like screen, pleasant to the eye at all times, a protection from cold winds, and in May it is a wall of golden flowers.

By far the best of the trees introduced in recent years from China is Davidia involucrata. Its praises have been sung by Henry, Wilson, and others, and to these may be added a strong recommendation from its behaviour in this country. The tree is quite hardy at Kew, never having suffered either from frost or from east wind in Spring from its first planting in the open some ten years ago. It grows as vigorously and is as shapely as a well-behaved young Pear tree, and it does not start into leaf too soon. The specimens planted out-of-doors at Kew are flowering well this year, and, judging by the tree in the Temperate House, when they are a year or two older they will bloom as freely as the wild Cherry. The tree in the Temperate House is probably the largest in this country. It was presented by M. Maurice de Vilmorin in 1901, and as soon as it was large enough it was planted in the Himalayan section of the house, where it grew well and flowered for the first time in 1913. It has flowered every year since, and at the present time there are more than a thousand fully expanded flower heads on it, a truly remarkable sight. Belonging to the Dogwoods, the pendulous flowers are in button-like heads, and set in a pair of white membranous, leaf-like bracts, the larger being about 6 inches long. These bracts have the effect of pieces of white paper hanging from the branches. Fruits are ripened every year, and some of last year's are hanging now. There were thousands of seedlings of this Davidia in Messrs. Veitch and Son's Coombe Wood nurseries a few years ago, and I suppose they were purchased by some enterprising nurseryman when the nursery stock was disposed of by auction.

I have never seen a Cornus at Kew so full of flowers as several young trees of C. Nuttallii near King William's Temple are now (see fig. 88). A visitor called them tree Clematis, and the white "flower," 4 inches across, with a black, button-like centre, certainly suggests a Clematis. In North America this and several other species of Cornus are very free flowering: evidently they like more sunshine than we get here. C. Nuttallii is said to be one of the most beautiful of the flowering trees of North America, and in autumn it is again effective owing to the yellow and scarlet tinting which the leaves assume.

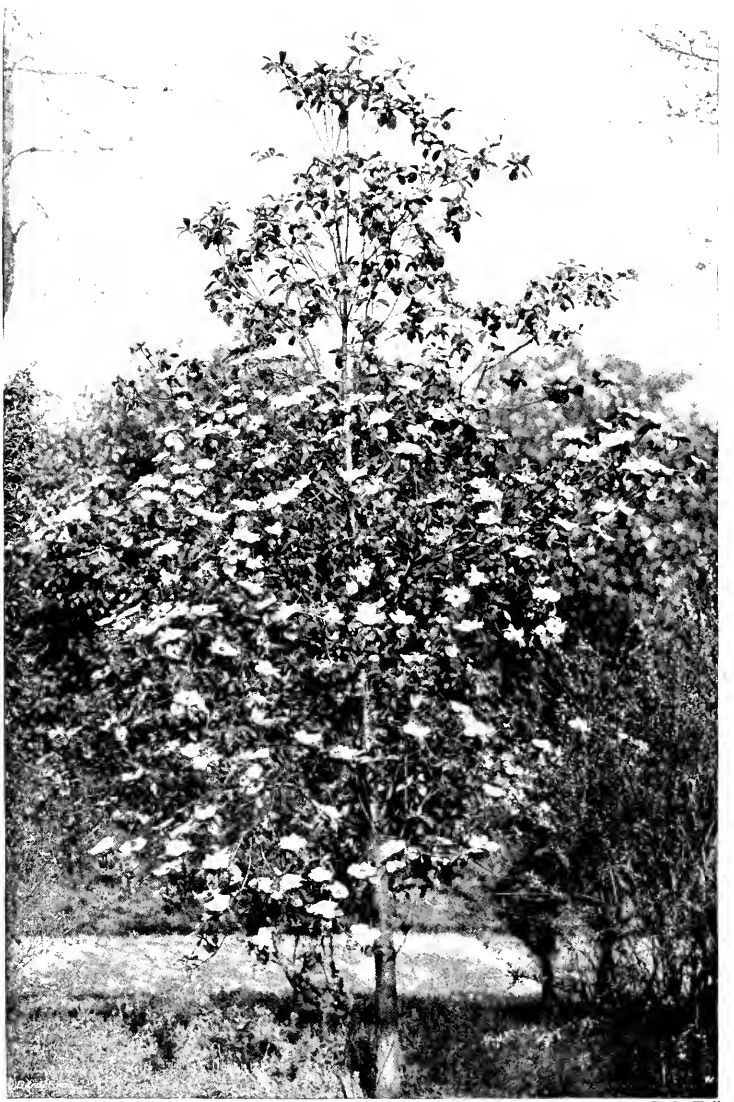
Amherstia nobilis, first flowered in England in 1849, by Mrs. Lawrence, the mother of the late Sir Trevor Lawrence, in her garden at Ealing Park, is represented by a large specimen in the Aroid House (No. 1) at Kew, which flowers regularly in May, and is in flower now. It is somewhat disappointing in this country, probably because it makes less show under artificial conditions than in the tropics of India and Malaya, where it is often cultivated in gardens, growing 40 feet or more high with a trunk 6 feet in girth. Dr. Wallich described it as being "profusely ornamented with pendulous racemes of large, vermilion-coloured blossoms,

* Previous articles appeared in the issues of January 19, February 9, March 9, and April 6.

forming superb objects, unequalled in the flora of the East Indies, and, I presume, not surpassed in magnificence and elegance in any part of the world." Given sufficient head room, say, a house 20ft high, it can be grown and flowered in a stove temperature such as suits its relations the Browneas and Jonesias. The tree produces long, leafy shoots every year, and the large, pendulous racemes hang among the big, pinnate leaves, the flowers dropping daily to the ground, for they are very fugitive. The blossoms are said to be used as offerings in the caves before the images of Buddha in Martaban.

In the Orchid houses the most noteworthy plants in flower are Lueddemannia Vyverensis, Schomburgkia tibicinis, and Epi rhyncostyloides. Other interesting plants in flower in the tropical houses are Puya coerulea, Til landsia Glaziovii, Nidularium Meyendorffii, Cereus flagelliformis, and Strelitzia Reginae. The seedling Victoria regia has just been planted in its big tank, where in about three months it will have leaves 6 feet across and flowers as big as Cabbages. I know no plant that increases so rapidly as this does; in about six months it produces scores of leaves which would together weigh about half a ton, and forty or fifty big flowers, not to mention the hundreds of grape-shot-like seeds which it ripens.

Standing over the Victoria tank is a good example of the Sealing wax Palm, Cyrtostachys Renda, which recalls its first appearance in Europe at a Ghent Quinquennial when I offered Mr. de Smet Duvivier 500 francs for a young plant which he showed there, and he refused the offer. Ah, me! Will there ever be such shows, such gatherings of plant fanciers from all parts of the world, such fraternising, and such trading as the mighty men of Ghent were used to organise every five years? Those gatherings were the Olympiads of horticulture. There, giant met giant; Sander v. Linden, Holford v. Vuylsteke, Wills v. Van Houtte, Vilmorin v. Krelage, and such-like leviathan contests. And what plants one saw at these shows! Shall we ever see their like again? Now, it is get on with the war; grow food; waste nothing. The world is struggling for freedom, and the art of gardening, like so much else that we valued, must drop its luxuries and help to provide food for the warriors. On the whole, we appear to be doing it fairly well. Nearly every man, and a large number of women, too, are actively engaged in their spare time in making the soil produce food. Many lessons are being learnt in the process, one of the most important of which is that vegetables are good for man. For food is a habit, a fashion, and we are apt to eat, and look upon as essentials, things that we could very well dispense with.



[Photograph by E. J. Wallis.

Fig. 88.—cornus nuttallii flowering at kew.

(See p. 203.)

Many Rhododendrons are in flower, both outside and under glass. In the Himalayan House, the most striking are The King and William Taylor, two hybrids raised at Kew; Loderi, white and rosy-mauve forms; Nuttallii, six flowers in a head; Griffithianum Rose Mangles, a lovely waxy flowered hybrid; and the true bright crimson arboreum. Outside, a bed of Vaseyi is a great attraction, and campylocarpum proclaims itself the best of all yellow Rhododendrons.

The rockery is coming on, although, as one soldier recently remarked to another, it will be better when the plants have covered all the soil and the stones! They might, if the weather were more propitious. Daphne petraea is one of the gems, a nice little colony of it being quite happy in the Saxifraga section. The best Primulas are chionantha and davurica, and Trillium grandiflorum is a king among its less showy brethren, cernuum, sessile, and erectum. Meconopsis is at present represented by three species, simplicifolia, grandis, and aculeata, and there are others coming on. The Bluebells are in flower, and so are the Lilacs and Azaleas. As a modern poet has sung, you should "Go down to Kew in Lilac time, it isn't far from London." W. W.

LEAF-MOULD BENEATH TREES.

It cannot be contended that the accumulation of leaves beneath trees may be removed with advantage. The leaf-mould serves a two-fold purpose—that of manuring and of mulching, and perhaps the latter, by which the moisture is conserved and the trees whose roots are comparatively near the surface, is the more important, for the trees with their blanket of leaf-mould are thus enabled better to withstand periods of summer drought. Nor should the winter value of the mulch be overlooked, for even during the hardest spell of frost the layer of partially-decayed leaves protects the ground below. As an illustration of the great value to trees of the fallen leaves, I have in mind a large Beech wood conveniently near to a country garden. Every winter, for very many years, hundreds of cartloads of leaves were removed from a portion of the wood and taken to the garden for making hot-beds, and, later, to be used as manure in the kitchen garden. From the gardener's point of view this was an admirable arrangement. But the most casual observer could not fail to note the difference in the condition of the trees in the Beech wood. One could see to almost a yard how far the leaf-raking had extended. Beyond, where nature's plan of manuring and mulching had never been interfered with, the trees, of the same age and in similar soil, were in marked contrast. Although most had become "stag headed" with

age, they were taller, larger in the bole, and the leaves retained their greenness longer in the season than those that had been denuded of their natural mulch.

The value of the annual fall from broad-leaved trees is so well recognised by foresters that mixed plantations of broad-leaved trees and Conifers are frequently made. In the arboretum a periodic top-dressing is a regular routine. At Dropmore the late Philip Frost carried out much of this admirable work. Profiting by this example I treated many of the specimens at Pencarrow with road scrapings and other material, though in North Cornwall the annual rainfall is much heavier. The good effect was soon seen, particularly in the case of an avenue of Araucaria imbricata on high, poor ground, where the trees had practically stood still for a dozen years, yet in three years after a liberal top-dressing they renewed their vigour and grew with remarkable freedom. *A.
